Gryphon Tire Co. To Expand

$221,000 in 7 Per Cent. Cumulative Preferred To Be Marketed

NEW YORK CITY, Oct. 25—The Gryphon Rubber & Tire Corp., this city, in order to take care of expansion, is offering through Boughton & Co., this city, $221,000 in 7 per cent cumulative preferred stock. Ten shares of preferred, $100 par, and two shares of common, $100 par, are being offered for $1,000. Gross earnings are estimated at $1,856,280.40. Operating expenses, including taxes, etc., are placed at $1,312,279.80, giving a surplus applicable to dividends of $544,000. The company's factory is now fully equipped and will be turning out 300 tires a day by Dec. 1.

This company was formed in 1915 to manufacture a tire manufactured extensively throughout Europe, the patentee being I. S. McGiehan of London, England. The American patent is No. 1,110,451, filed May 15, 1911. The tire is composed of a fabric carcass or foundation and a tread portion composed of layers of rubber-filled fabric of different widths formed into a crescent band, united thereto by an interposed film of softer rubber, all homogeneously vulcanized.

The company is capitalized with $650,000 common and $350,000 preferred. The directorate includes S. A. Cunningham, president of the Bankers Safe Deposit Co.; C. W. Hunt, secretary of the American Society of Civil Engineers; J. W. Jones, president of the Jones Speedometer Co.; P. S. Jones; R. M. Owen, president of the R. M. Owen Co.; N. W. Peters; H. W. Schuette; H. A. Weatherbee, president of Arnold, Constable & Co., and D. W. Whipple.

—

Amazon Tire Enlarges Plant

AKRON, OHIO, Oct. 28—The Amazon Tire & Rubber Company, Akron, Ohio, have found it necessary to increase its floorspace. The factory is at present turning out about forty-five tires a day, and when the new four-story brick building is completed the production will average 300 tires daily. The company is building a standard tire with an extra side wall breaker strip, or blowout protection, added.

—

New Plant for Racine Tire

RACINE, WIS., Oct. 28—The Racine Auto Tire, Racine, Wis., organized 7 years ago to manufacture tires, tubes and rubber goods, will undertake the construction and equipment of a large new plant during the winter months to enable it to handle the fast growing volume of business. The present quarters at Fourteenth and Clark Streets have been overcrowded for many months, but not until this week was it possible for the company to purchase a desirable site. A deal was closed for the 4-acre tract on North High Street and the Chicago & North-Western tracks, known as Racine Baseball park, and approximately $100,000 will be expended in the erection of a group of new buildings. When this is completed, the present force of 125 workmen will be doubled, and the production of 250 tires and tubes per day increased to 600 of each. Plans for the factory will be prepared early in November, and contracts awarded, so that occupancy can be taken on or before July 1, 1917.

—

Tire Plant for Toronto

NEW YORK CITY, Oct. 27—A factory in which pneumatic tires of both the fabric and the cord type will be made has just started to operate in Toronto. This is owned by the van der Linde Rubber Co. and is backed by several men who have been interested in the Canadian developments of Bakelite by the firm of Plastics, Ltd. It is understood that the two concerns will work together although they will have separate financial organizations. Deliveries of tires are due to commence about the middle of January and only the fabric type will be made at first.

The company has a new design of cord tire in which the threads are arranged almost radially instead of at the considerable angle customary in cord tire construction. This is claimed to give the casing a greater strength and also to increase its resiliency from 2 to 5 per cent. A special form of tube is being made of red rubber treated so that there is little tendency for it to split should a blowout occur. It is stated that in the event of the shoe failing the damage to the tube is confined to the same size as, or smaller than, the hole in the casing, this making it easier to repair the tube.

—

Gillette Tire to Operate Dec. 1

EAU CLAIRE, WIS., Oct. 28—The Gillette Safety Tire Co., Eau Claire, Wis., will not be able to commence operations in its new plant until Dec. 1, because labor troubles at Akron, Ohio, have delayed the completion of the extensive factory and equipment. The original plan was to be ready to start production July 1, and the date then was deferred to Oct. 1, but further delays were encountered in getting the equipment. The buildings are completed and ready for the installation of machinery, which will begin shortly after Nov. 1, according to assurances received by the company.

Bradley on Italian Front

The Automobile Correspondent Doing Ambulance Work—Studies Trucks

NEW YORK CITY, Oct. 31—W. F. Bradley, European correspondent for THE AUTOMOBILE, is now doing ambulance work with the British ambulance unit on the Italian front where he has been for several months and where he will be for several months to come. Mr. Bradley is making a very close study of motor truck use in all stages of army work on the Italian front and is very close in touch with transportation matters in general in that zone. When his service with the ambulance unit is completed he will devote his time to a series of articles for THE AUTOMOBILE, covering this field of the work. His work as ambulance driver takes him well to the front, in fact, he is operating most of the time in advance of the Italian artillery. His work is removing the wounded from the front to depots 10 to 20 miles to the rear according to the nature of wounds.

In this work he has an excellent opportunity of observing the mechanical defects and shortcomings shown by the different makes of vehicles in actual service. The vehicles employed include American, French, Italian, English and German. It is questionable if at any other point in the European war zone motor vehicles are receiving more severe service. On the Italian-Austrian front there is a combination of mountains, bad roads and extremes of climate which severely tax all motor equipment.

No European war correspondent has had a better opportunity of first-hand study of motor apparatus in the war zone than W. F. Bradley. Besides being a correspondent of the first rank he is an engineer of standing and is familiar with European practice in automobile and motor truck construction. He is acquainted personally with 75 per cent of the European engineers, has visited each year for several years the majority of the French, Italian and English factories, and has driven over the greater part of these countries. There is no one in the technical line better qualified to report the status of various automobiles and trucks in war service than he. During the past year he has been in the ambulance and other services on the Flanders front and has been over all of the fighting zone in France. His articles covering the Italian front should begin during the months of February or March.

Colonial Motors Making Deliveries

DETROIT, MICH., Oct. 31.—The Colonial Motors Co. is now making deliveries of

motors at a rate of 5000 a year and expects within the coming year to produce from 12,000 to 15,000. The company which was organized Sept. 1 with a capitalization of $200,000 of which $50,000 is in preferred stock and $150,000 is common stock, is now producing its motors in a four-story building of 50,000 sq. ft.

C. S. Briggs, president, was president and general manger of the Krit Motor Car Co. in 1909, and the manager of the Brush Runabout Co. in 1910. E. D. Moessner, treasurer, was formerly the treasurer of the Brush Runabout Co. and the Briscoe Mfg. Co. until he resigned in 1911 to join Mr. Briggs when he formed the Briggs-Detroiter Co.

Texas Co. Reduces Price 1 Cent

NEW YORK CITY, Oct. 29—The Texas Co. has reduced the price of kerosene 1 cent a gallon in Texas. It has cut the price of gasoline 1 cent and kerosene 1 cent a gallon in New Mexico.

—

Gasoline 1 Cent Lower in Denver

DENVER, COL., Oct. 28—Another 1-cent drop in the price of gasoline has occurred, bringing the price to 21 cents at all the filling stations and many garages. Some garages charge a few cents more, on the ground that they handle gasoline mainly as an accommodation and cannot afford to bother with such a small volume of business for the 2-cent margin of profit maintained by the regular filling stations. The wholesale price to the filling stations and garages is 19 cents, while the price direct to consumer from the oil company's tank wagons in 25-gal. lots or more is 20 cents.

This is the fifth reduction of 1 cent within the last 3 months, following a long period when the retail price stood at 25 cents. The other changes took place on Aug. 14, Sept. 8 and Sept. 26.

—

Harroun Motors Begins Building

DETROIT, MICH., Oct. 27—The Harroun Motors Corp. has broken ground for its first building at Wayne County. The structure will be 550 by 75 ft., two stories high and will have a wing of saw-tooth construction 140 by 600 ft. and one-story high. Both buildings will be built of brick and steel.

The Harroun corporation, according to officials of the company, have already signed applications for more than 50,000 cars from dealers throughout the United States. In addition more than $1,000,000 worth of cars have been contracted for for export.

—

Plank Shaft Co. to Enlarge

GRAND RAPIDS, MICH., Oct. 25—The Plank Flexible Shaft Machine Co., this city, is considering plans of reorganization with a capital of $200,000 for the manufacture of a new flexible shaft for automobile work.

S. A. E. Day Success Assured

—

516 Tickets Sold for Frolic Performance and 294 for Annual Dinner

NEW YORK CITY, Nov. 1—It is now assured that Thursday, Jan. 11, which is S. A. E. Day of New York show week, will be a success, not only from a business and professional standpoint, but also from the social side. To date 516 tickets have been sold for the special performance of the Ziegfeld Frolic for that evening, or two-thirds of the entire seating capacity of the theater. The annual dinner to be held in the grand ballroom of the Hotel Biltmore promises to outdo any similar occasion in the history of the society, 294 tickets having been sold up to the present. Last year no campaign for disposing of the tickets to the dinner was undertaken until 6 weeks before the event occurred, so this year it looks as though the grand ballroom will be filled to capacity.

—

Metropolitan S. A. E. Meets Nov. 16

NEW YORK CITY, Oct. 28—The Metropolitan Section of the Society of Automobile Engineers will hold a meeting Nov. 16 at 8 p. m. at the Automobile Club of America. "Some Present and Future Scientific Problems of the Automobile" will be the subject of C. F. Kettering's address. Mr. Kettering is vice-president and general manager of the Dayton Engineering Laboratories Co., Dayton, Ohio.

—

Truck Converter Contract in Dispute

CHICAGO, ILL., Nov. 1—Whether a binding contract has been negotiated between the Smith Form-A-Truck Co. of this city and the Redden Motor Truck Co., of New York, with regard to a truck converter patent issued to Albert E. Cook and controlled by the Redden company, is a matter in dispute to-day and one which apparently the courts will have to settle. Some weeks ago the Redden Motor Truck Co. announced that it had a signed contract with the Smith Form-A-Truck Co., whereby the latter concern signed to recognize the validity of the Cook patent and to pay royalties, the contract giving the Smith Form-A-Truck Co. the right to manufacture under the Cook patent.

This contract matter is now in dispute, the Smith Form-A-Truck Co. contending that the so-called contract is not in reality a contract, but only a memorandum which was signed by E. I. Rosenfeld, vice-president and treasurer of the Smith Form-A-Truck Co. The Smith company repudiates this alleged contract and has filed suit against Albert E. Cook and Chas. W. Hills, attorney for Cook and Redden, to restrain the latter from representing that they have a valid contract with the Smith Form-A-Truck Co. in which the Smith organization agrees to pay royalties. The suit entered by Smith also asks that the defendants be restrained from intimidating dealers and agents of the Smith company.

The Redden Motor Truck Co. claims that the so-called agreement or memorandum is a binding contract and that Mr. Rosenfeld declared himself authorized by the board of directors of his company to conclude such agreement.

—

Watson Heads Pennsylvania S. A. E.

PHILADELPHIA, PA., Oct. 27—John W. Watson, president of the American Bronze Co., Berwyn, Pa., was elected chairman of the Pennsylvania section of the Society of Automobile Engineers at its annual meeting held here last night. A. K. Brumbaugh, assistant engineer, Autocar Co., Ardmore, Pa., was elected secretary and T. Y. Olsen, vice-president the Tinius-Olsen Testing Machine Co., Philadelphia, treasurer.

Herbert Chase, chief engineer of the Automobile Club of America, read a paper on the Otto versus the constant pressure cycle, supplementing his paper on the same subject presented before the Summer meeting of the society.

The next meeting of the section will be held Nov. 23, when John Younger, chief engineer, motor truck department Pierce-Arrow Motor Car Co., Buffalo, N. Y., will present a paper on brakes.

—

Detroit Motor Lock Co. Formed

DETROIT, MICH., Oct. 30—The Detroit Motor Lock Co. has been incorporated with a capitalization of $30,000 to manufacture and license others to manufacture, automobile parts. C. R. Kerns, G. M. Conner and R. W. Muir are among the incorporators.

—

Webster, Gramm Truck Man Dies

DETROIT, MICH., Oct. 27—J. K. Webster, formerly secretary and treasurer of the Gramm Motor Truck Co., who was forced to retire from the company because of ill health died here today.

—

Silver to Give Up Peerless

NEW YORK CITY, Nov. 1—The Peerless business in this city will be handled after Jan. 1 by a factory branch. C. T. Silver, who has had the agency since Jan. 1, 1914, is relinquishing it to concentrate on the Chalmers and Dort lines, which he recently took over. The Peerless branch will be in the former Paige location at Broadway and West Sixty-third Street and will handle both wholesale and retail.

A. A. A. Disqualifies Two Makers

Grant and Lozier Come in for Disqualification—New Rules for 1917

NEW YORK CITY, Oct. 31—At to-day's meeting of the contest board of the American Automobile Assn. two automobile manufacturers were disqualified and fined for not advertising in accordance with A. A. A. rules as governing performances of cars in contests. The Grant Motor Car Co., Findlay, Ohio, was disqualified for 1 year, beginning Oct. 1, 1916, for advertising in connection with the performance of its car at the recent Pike's Peak Hillclimb. In addition to disqualification for 1 year a fine of $500 was imposed. The disqualification prevents it from competing in sanctioned events during the period stated. The Hal Motor Car Co., Cleveland, Ohio, was given the same punishment for advertising in connection with the hillclimb recently held at Giant's Despair, Wilkes-Barre. Other cases of advertising not being in accordance with results of contests are being investigated by the contest board, and decisions are expected at the next meeting of the board.

The Kalamazoo Motor Speedway, Kalamazoo, Mich., was permanently disqualified due to checks covering cash prizes, etc., going to protest. This is the speedway where the fatal accident happened at its 100-mile race on Aug. 27, in which three men were killed and eleven cars wrecked. The disqualification applies to the officers of the association.

To Revise Rules

The question of revising speedway rules for the coming year was taken up. Several changes were made in the rules, all for the betterment of racing. The suggestion that more cars, namely, forty, be permitted to start on a 2-mile speedway was overruled, and the number of starters in any race will remain as it was this year. The objection to more starters was largely due to the difficulty of scoring greater numbers.

The position of assistant starter was eliminated. A new position known as Clerk of Course was created. The clerk of course will have complete supervision of the track during the race, as well as immediately previous thereto.

The use of judges in connection with races has been discontinued largely because there have not been specific duties for them and too frequently they have gotten on the track and increased the congestion there.

The question of qualifying trials for speedway races has not been satisfactory this year. Speedways have charged admission to spectators for qualifying trials and frequently spectators have spent nearly an entire afternoon without getting any show for their money. This has been due to few cars presenting themselves for qualification. To avoid this speedways will be requested to have only one day for qualifying trials at which admission can be charged.

Cars will continue to start in races in order of their qualifying speeds. The cars that qualify will only be given one chance, providing they meet the qualifying speed for the race. Should they not show qualifying speed they will be given two additional trials. Cars qualifying after the official date set for trials lose their starting positions which the regular qualifications would have entitled them to.

The board practically accepted many of the recommendations which had been discussed at a recent meeting of the speedway managements, drivers, and the contest board. These included the following:

A—For 1917 no speedway championship events will be for distances less than 100 miles.

B—The minimum purse for championship events will be at the rate of $100 per mile.

C—No sanctions will be issued for Sunday races of any character.

D—In case a race is prematurely terminated due to accident the disposition of prize money rests with the contest board and the referee.

E—All prize money in excess of $5,000 must be in office of contest board not later than 10 days before scheduled date of race. It must be deposited as a certified check or satisfactory bond. Prizes of $5,000 or less must be deposited in cash or certified check with contest board representative not later than 10 days before scheduled date of contest.

F—No driver shall work on his car between the hours of 8 p. m. and 6 a. m. the night previous to a speedway race.

G—Drivers and cars will be assigned 1917 registration numbers according to championship standing in 1916. The car will carry its same racing number throughout the season.

H—Pit supplies must be on the speedway grounds not later than 5 hr. before scheduled start of the race and in the pits not later than 3 hr. before the start.

I—Speedways will pay the contest board $10 for each car which qualifies and starts in a championship event. The fund so obtained will be added to the championship award fund.

J—The 1917 championship award fund will be divided into five parts. First five drivers must appear at all championship events, unless excused by chairman of contest board, on certificate from technical representative of board, or from physician.

Numerous other minor changes were made in connection with the rules. One was to the effect that all timing and scoring records of any race must immediately after the completion of the race be turned over to the representative of the contest board or the referee.

Chairman Richard Kennerdell of the contest board has decided to visit California for the Vanderbilt and Grand Prize races.

—

Estep Goes to Salonica

NEW YORK CITY, Oct. 26—E. R. Estep, formerly in charge of the Packard advertising, sailed last month for Salonica to furnish war news to a syndicate of daily papers. Mr. Estep has been much interested in the war and last autumn visited Verdun and other points on the western front.

Chevrolet's Great Development

New Departments, Increased Floorspace, Additional Machinery and Buildings

FLINT, MICH., Oct. 30—Two large buildings completed, two more in process of construction, several new departments, installation of hundreds of lathes, presses and milling machines, and double the number of workmen are some of the recent developments at the factory of the Chevrolet Motor Co.

One new building 150 by 1000 ft. has just been completed and is now used for an axle plant, engine works, transmission assembly and heat treating plant on the lower floor and as a tool room on the second floor. Next to it and of the same dimensions, is another structure recently finished which serves as an engine works and stockroom. The machinery is erected in the center of the floor, the stockrooms running along one wall with numerous doors from which the tubing, raw castings and other material can be fed directly to the workmen. Both plants are built entirely of steel, brick and glass and embody a novel and valuable lighting and ventilating system. The two walls in each structure, 1000 ft. long, are constructed of glass supported by steel and the thousands of windows are arranged on shifting mechanisms allowing them to be opened at will and throwing a powerful light into every corner of the interior, besides providing excellent ventilation. This system is supplemented by additional glass built in V shape on the roof which also has the sliding shaft allowing each window to be opened. Both structures are equipped with hundreds of new lathes, presses, milling machines and ovens.

A large building constructed in U shape with two sections each 80 by 1000 ft. and three stories high with a court 50 ft. wide in between, is in process of erection and will be used for the assembly of the "four ninety" model when completed. It is built of brick, glass and steel and will probably be ready for occupancy Dec. 1. Directly behind it the company is building a four-story structure which will serve as a power house and heating plant thus giving all necessary power from within the institution.

466,000 Sq. Ft. Added

The new buildings give the company 466,000 sq. ft. of floorspace in addition to their present equipment. There are now double the number of workmen employed 1 year ago and the completion of all buildings in process of construction will witness the addition of 1000 more men.

Many other interesting and important

features have been introduced. There is a large top department where the company paints and attaches Winter tops for the "four ninety" model when so ordered. Many new ovens have recently been purchased and installed for the paint department which have been found to greatly facilitate that work. The frames with the engines and gasoline tanks attached are placed upon trolley conveyors and sent through the first ovens following a coat of paint put on by the flow system. They emerge and pass a short distance, by which time they dry and are ready for varnishing and the second series of ovens. The varnishing is done by spraying machines. All painting is accomplished by the flow method. In the body room one may see a number of bodies arranged upon roller wheeled trucks and standing directly under a long heavy pipe filled with paint. Numerous short thin pipes feed from the main line and each is attached to rubber tubing which ends in a nozzle from which the paint flows by gravity force. Each nozzle is directed by a workman so that the paint reaches all parts of the body flowing from the upper edges to every section below.

—

Stutz Wins Tucson Race

TUCSON, ARIZ., Oct. 30—R. H. Delno of Tucson, driving a Stutz, won the 50-mile free-for-all race at the Southern Arizona Fair on Oct. 27 in 51:28. Charles Miller, in a Fiat, took second place. The race was marred by a series of accidents in which three cars were wrecked and four men were injured. There were only five cars entered in the race.

—

Hupp United America Car in California

DETROIT, MICH., Oct. 28—The Hupmobile United America car left Salinas, Cal., yesterday bound for Santa Barbara. The party reached Salinas, en route for Universal City on Oct. 26, coming directly by way of San José and San Francisco.

—

Baldwin Is Saxon Service Manager

DETROIT, MICH., Oct. 28—G. O. Baldwin has been appointed service manager of the Saxon Motor Car Corp. Mr. Baldwin was formerly connected with the service department of the Studebaker Corp.

—

Tractor Demonstration by Bullock Co.

DETROIT, MICH., Oct. 30—The Bullock Tractor Co. has secured 2000 acres of land in Schoolcraft County, Mich., and will demonstrate tractors in farming operations. Practically all of the work on the farm, of every character, will be done by motor power.

Maxwell Issues Open Challenge

All Cars at $1,000 or Less Eligible for Speed and Economy Tests

DETROIT, MICH., Oct. 28—The Maxwell Motor Co. has issued an open challenge to all companies making automobiles to sell for $1,000 or less to compete in speed or economy contest.

The challenge states that the tests are to be conducted by newspaper men or other disinterested parties, and that the tests for speed and economy are to be held between Detroit and any other cities in Michigan. Results of the contests are to be made public through the newspapers. The only provisions specified are that the car must be a stock machine selling for $1,000 or less and that the maker or his authorized agent stands sponsor for the car.

—

Accepts Maxwell Defi

G. H. Maines, Flint, Mich., has notified the Cunningham Auto Sales Co., this city, that he accepts its challenge to pit a Maxwell stock car against any other car selling for $1,000 or less, in a speed and economy race in Michigan. Mr. Maines accepts in behalf of the Chevrolet four-ninety, and suggests a race from Detroit to Pontiac, Flint, Lansing and return to Detroit by way of Jackson.

—

September Exports Lower

(*Continued from page* 729)

9 months of this year they were 47,246 cars, valued at $32,291,633. There was also a big gain in the exports of parts, not including engines and tires, which showed a gain in value from $10,994,859, in 1915, to $17,322,349, in 1916.

In point of value among the purchasers of American-built cars among the warring nations of Europe during September last Russia held first place, that country's imports of American cars amounting to 670 cars, valued at $1,957,287, while the United Kingdom was second with purchases amounting to 700 cars, valued at $1,684,579. Russia did not figure in the export returns in September a year ago, but the United Kingdom was there to the extent of 2650 cars, valued at $3,119,806, while during the 9 months of last year the latter imported from this country 19,434 cars, valued at $28,648,749. Russia does not figure in the 9 months 8 returns of this year.

653 for France

France imported 653 cars, valued at $1,523,761, from this country in September last, as against 421 cars, valued at $916,830, in September a year ago. That country's purchases during the 9 months' period showed a gain from 4885 cars, valued at $12,126,628, in 1915, to 6497 cars, valued at $16,529,055, in 1916.

Little Denmark figured to the extent of 177 cars, valued at $139,301, in September, last, and 936 cars, valued at $714,412, during the 9 months of this year, Denmark not being included separately in last year's returns. There were 1144 cars, valued at $3,341,676, exported to "other Europe" in September a year ago, as against 248 cars, valued at $232,579, shipped there in September last. For the 9 months' period these shipments decreased from 6688 cars, valued at $18,082,964, in 1915, to 3102 cars, valued at $3,867,419, in 1916. Of course it is to be understood that some of the exports to "other Europe" are included in the figures given elsewhere.

—

Black and White Taxicabs in New York

NEW YORK CITY, Nov. 1—The Black & White Cab Co. is now running its full force of taxicabs on the local streets. At the present time there are about 200 of these in service. This company is featuring its service with much lower rates, regardless of number of passengers up to five, which are 20 cents for the first one-third mile and 10 cents for each additional one-third mile. Thus the first mile will cost 40 cents, and all miles thereafter will be 30 cents. These new taxis have electric lighting and an electric device on the outside of the car which illuminates the numbers on the houses and assists the driver in readily finding places. The car presents the appearance of a private limousine. In the Winter it will be equipped with heating apparatus and rugs.

—

24-Hr. Endurance Run in New Jersey

NEWARK, N. J., Oct. 30—A 24-hr. endurance run will be held by the New Jersey Automobile and Motor Club, this city, on Nov. 24 and 25. The run will start and end in this city, and the course will be through North Jersey, covering 250 miles. The competing cars will be divided into two classes. One class will be composed of touring cars and the other of runabouts.

—

94 Car Exhibitors at Los Angeles

LOS ANGELES, CAL., Oct. 28—The second annual show of the Los Angeles Motor Car Dealers' Assn. opened this afternoon with ninety-four exhibitors, displaying 226 cars. There are twenty-one accessory exhibits. Fifty makes of gas cars, twenty-two trucks and two electrics are shown. A three-story building and two tents provide more than 55,000 ft. of floor and 6000 visitors were admitted this afternoon.

Truck Progress

THE outstanding feature of 1916 from the viewpoint of the truck industry is the immense increase in production. The truck bearing the 1917 stamp is, on the average, a better truck than its immediate prodecessor; there have been many engineering developments of a character which show that the truck is settling down into a condition of engineering stability far greater than has ever been the case before. But these lesser things sink into insignificance beside the production figures and the record of factory expansion.

The truck business has been coming for years and it has hardly yet "arrived" in a final sense. The truck industry, as distinct from the passenger automobile business, is not yet beginning to stir the imagination of the financiers, and perhaps this is just as well. The automobile industry had to go through some hard times before it became a staple industry; its finance has often been none too sound in character, in fact it will be some years yet before it is on a really permanent basis. If the truck industry as a separate thing can be allowed to grow more slowly and consolidate itself as it goes, it will be so much the better for it in the end.

The truck industry is a part of the automobile industry in one way, but it is a separate thing in many others; so separate that men experienced in passenger car work, either engineering, sales or in some other capacity, may actually be less fitted for similar positions in a truck firm than outsiders who have no passenger car experience behind them. One might almost liken the two to the army and the navy, sister services, but with totally different duties and procedures. For this reason the financial handling of truck businesses ought usually to be distinct, and the present indications are that this will be so.

Power Braking

WHETHER the device described elsewhere in this issue of THE AUTOMOBILE provides an ideal method of using the engine power to apply the brakes of a car, or whether it has some drawback yet to be discovered, it marks a step in the right direction. That the power of the driver's leg should be utilized to apply the whole retarding force to an automobile is just as absurd as to require hand starting for an engine already provided with an electric generator.

We have eliminated hand cranking, we have electric transmissions and electric gearshifts, we have reduced the pedal pressure necessary for the clutch manipulation, but brakes have not been made any easier to apply. Thus a power brake is a logical step, as logical for an automobile as for a street car. The electrically applied brake has been with us for some time, and it is a remarkable thing that it has not been appreciated. Perhaps it will be now that we have this new vacuum brake which unquestionably will be tried out on a large scale. Directly any number of manufacturers begin to experiment with these devices we shall see the engineering brains of the profession turned to the consideration of brakes in general and the result cannot be otherwise than to cause a great improvement to take place.

Credit Where Due

AFTER the Astor Cup race at Sheepshead Bay THE AUTOMOBILE criticised the management of the track somewhat severely, particularly with respect to allowing the crowd to get on the speedway itself. Last Saturday the Harkness Trophy race was handled much better, the worst feature being the tardiness in the announcement of times and speeds, though this was better than on the last occasion. Better facilities must be used to quickly advise the grandstand of times, incidents, etc. The track guards were as efficient as could be desired.

The pitiable thing was the meager sprinkling of people. It was a great day and there was great racing, yet to look at the stand there might have been a cutting northeaster blowing and only a half-dozen second rate cars on the track. New York has not yet been awakened to the existence of the speedway. It is not apathy on the part of the public, but lack of sufficient means to let that public know when races will take place and what sort of races they will be. The New York public has a thousand attractions thrust before it every day and the speedway needs a few good thrusters to help draw in the crowds that would come if they thought of it.

The Truck's Emancipation

Truck Engineering Now Separated from Passenger Car Design—Many Factors Have Contributed to Evolution — Early Originality Choked by Passenger Car Influence Now Reasserting Itself

By A. Ludlow Clayden

THE design of commercial chassis is not yet as far advanced as that of passenger cars. The motor truck is not yet quite so good for its specific purpose as is the passenger car for its particular class of service. The reason is that the requirements of a motor truck are so much more difficult to meet; the task of the truck engineer is harder than that of his passenger car brother.

The history of the truck has been very interesting. It was the earliest ideal and, if we eliminate the very first years of all, it is safe to say that the success of the railroad in cheapening and expediting the transport of goods inspired a great number of men with the idea that mechanical power ought to be used similarly upon the roads. It is an undoubted fact that the engineering profession generally looked upon the development of the motor truck as quite reasonable at a time when it was ridiculing the passenger car movement.

Practical Trucks Fairly Recent Product

However, despite the greater age of the motor truck idea, it is only within the last few years that we have had really practical machines, and the advance since about 1908 has been greater than in the whole of the previous century. There have been several stages in the modern development of the truck. Sixteen years ago Europe had a number of quite good steam vehicles, and there was some tendency in America to follow the foreign lead. How strong this movement was in England particularly, can be seen by the fact that the heavy vehicle section of the London show in 1904 contained but three gasoline machines, while there were ten exhibits of steam lorries, and of the three one was a very light van.

At the same period in America there was no marked tendency in truck engineering, unless it was toward the electric. Neither for commerce nor for pleasure has the electric ever been more than a curiosity in Europe, but America, thanks to her magnificent electric power stations, was able to build quite good battery cars of all sizes at an early date. There was little or no trouble even in 1900 in making a chassis that would stand up, nor in designing satisfactory electric motors; the battery was the weak spot. Still in the early days of this century electric vehicles were operating with reasonable economy, and the struggle to produce steam or gasoline machines was stimulated as much by a desire to increase the speed and possible operating radius as to overcome any lack of reliability in the electric. It is not easy to draw an exact parallel, but it is not far from the truth to say that in 1905 the steam lorry in Europe and the electric truck in America occupied about the same position in usefulness and public estimation.

Both in Europe and in America, but more especially in the latter country, a very curious situation was to be observed in the years between 1900 and 1907. The manufacturers of passenger cars were provided with two pioneer examples or models, these being the Daimler as originally produced in Stuttgart and the Panhard in Paris. Almost every European manufacturer copied one or other of these two and the majority copied both. In America there was greater originality, but the passenger car men soon turned to copying Europe, except for a small minority of whom Charles E. Duryea was probably the leader. On the whole, however, the passenger car manufacturer has never changed his engineering in such a way that it cannot be traced back to Panhard or to Daimler.

Not so with the truck industry. There seems to have been a fixed impression up to about 1903 in Europe and till a much later date in America that the truck had essentially to be something quite different from the passenger car. The Panhard sliding gear transmission, for example, while admitted for a passenger car was regarded as quite unsuitable for heavy work, and the quickly attained agreement that four cylinders was the minimum for pleasure cars had little effect upon truck engine design. As late as 1906 the typical American gasoline truck, if there was such a thing, had a two-cylinder engine, under the body frequently in conjunction with a planetary transmission and often a single chain drive to a live rear axle. This was partly owing to a strong idea that the ideal truck had the maximum of body space with the minimum of overall dimensions, and accessibility of engine and running gear was sacrified in order to get short wheelbase. Of course the makers of gasoline vehicles had the electric as an example in this respect which may be another reason why so few firms in 1906 or so were developing the type of truck almost universal to-day which had the general layout of the passenger car chassis despite great differences in detail.

Worm Drive at First Truck Show

At the first commercial vehicle show held in America at Chicago in December, 1907, an analysis of the twenty exhibits shows that nine firms were using sliding gear transmission, three planetary gearing and three friction drive: four were electrics and one a gas-electric car. It is also worthy of note that a "startling novelty" was the Mitchell truck with worm drive. Only one of the trucks exhibited had the engine under a bonnet. This show took place at the end of 1907, so to jump to the New York exhibition of January, 1912, is to leap a period of 4 years. Between the machines here shown and those at the 1907 exhibition there is surprisingly little difference, judging by exterior views. *The Commercial Vehicle* published specification tables for the 1912 show, similar to those appearing in this issue of THE AUTOMOBILE, and in them is seen that the majority of light trucks had one, two or even *three*-cylinder engines, at a time when the passenger car was not much different from what it is to-day. Certainly the larger trucks had four-cylinder engines, but friction gearing and planetary gears

were still popular in all sizes and very common for the lighter vehicles. The beginning of the engine under bonnet era is quite noticeable in the machines of this date. The previous year, 1911, is also noteworthy in truck history, because it was in the summer of that year that the Pierce-Arrow worm-drive truck came upon the market, this being a European design so far as layout went and American in all matters of strength. This Pierce-Arrow vehicle certainly marked a definite point in American truck engineering, because it was the pioneer of a type that is in wide employment to-day.

The influence of the manufacturers of passenger cars upon truck engineering has been very considerable. Some of the leading passenger car makers made a success immediately upon entering the truck field, others did not do so, but in the first category must be mentioned Pierce, who had a complete new design in 1911 and White, Peerless and Packard who adopted a more usual method and an easier one, of getting into the second branch of the automobile industry. Knox also should be mentioned as an example of a concern which gradually dropped passenger cars altogether and became truck makers only.

By 1910 or thereabouts most of the leading passenger car builders had developed engines of a very rugged character which were quite reliable and fit for somewhat heavier duty than they normally received. A good number had transmissions arranged amidships which were stout enough to withstand constant gearshifting and possessed a high degree of reliability.

Converted Passenger Cars

The makers of such cars argued with themselves that the essential difference between a passenger car and a truck laid in the strength of the frame and axles, it being essential that these should be able to support a greater load and be able to withstand more severe road shocks. It was therefore a very natural and a very easy development to take the existing transmissions and engines and mount them on a channel steel frame and to provide the transmission with a jackshaft, propelling the rear wheels by means of a pair of chains. Subsequent development has shown that the passenger car engines and transmissions of about this date were really too massive and for this reason they were well able to stand up under the severer conditions of commercial service. To make forged axles of sufficient strength and to build a frame which would not bend were neither of them difficult achievements, so that the established passenger car maker using his already well-tried powerplant and having only frames and axles as new parts was in a somewhat better position than a specialist on truck manufacture who had to develop engines, transmissions and everything simultaneously.

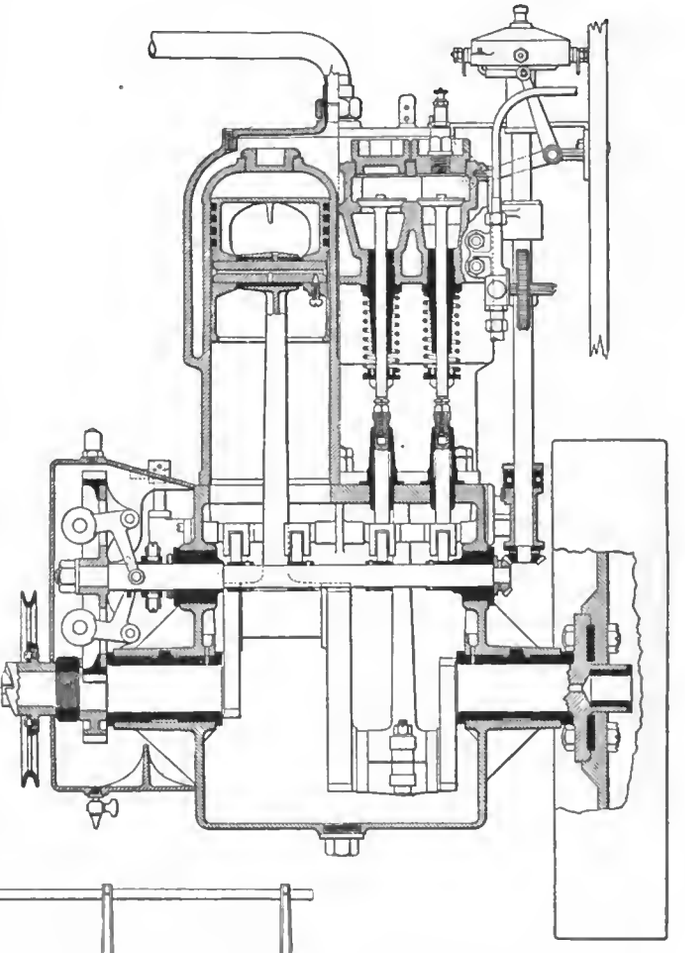
Packard was one of the earliest of manufacturers to add a truck to an existing passenger car line, bringing out a two cylinder vehicle in 1904. This had an engine which was practically half the four-cylinder touring car motor, which was then new, and the transmission was identical with the passenger machine. The illustrations of this car taken from *Motor Age* of 1904 show that the truck of 12 years ago had some points of resemblance to that of to-day.

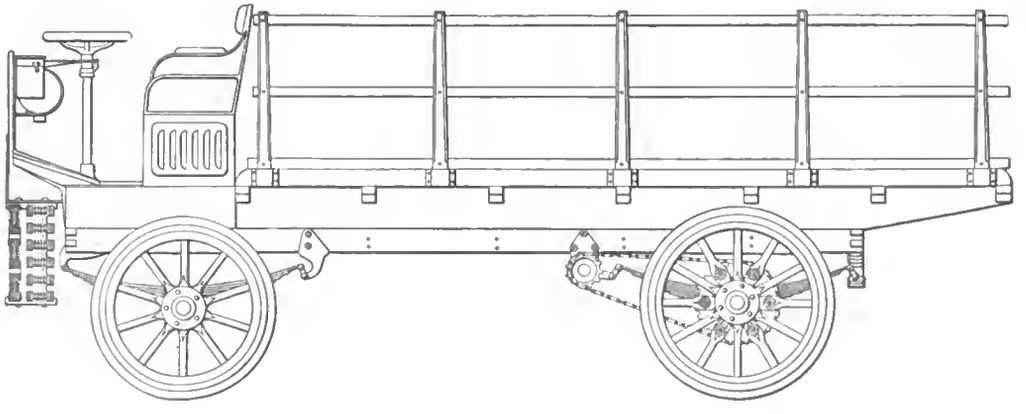
Stock Parts Makers Enter Field

Some of the machines originally created by this method are still being made in practically the same form in which they were originated. Others have but lately been changed by a complete redesign and, meanwhile, the makers of stock engines and other stock parts have entered the commercial vehicle field making large use of their passenger car experience while so doing.

The action of the first passenger car makers breaking into the new field coupled with the development of the stock part manufacturers has completely altered the general makeup of the truck. It was said at the beginning of this article that the majority of passenger cars could always be traced back to Daimler or Panhard and this has now come to be true in the majority of trucks.

Analyzing the development of the truck in this way one is faced with a problem impossible of solution, and this is





Drawings of the first Packard truck with two-cylinder engine and the same transmission as was used at the time for the Packard touring car. Packard used touring car parts in trucks for many years quite successfully

whether the average truck has a four-cylinder vertical engine under a bonnet and sliding gear transmission and some kind of live rear axle, due to the fact that these details comprise the best machine, or whether it is due to the fact that the entrance of passenger car makers into the truck field exercised an overpowering influence on truck design.

For example, the reliability of the present-day truck is extremely good. It is so good that the necessity for placing the engine under a bonnet and so wasting 2 or 3 ft. of frame is still debatable. The passenger car makers used a bonnet because it was their practice, thus following in the footsteps of their European predecessors. We do not know for certain whether it might still be worth while to seat the driver on top of his engine.

Original Design Still Existing

It is unfortunate that so many of the very early truck makers went out of business, for had they continued to exist we should have been better able to judge the real virtues of different types of design. Just to mention one outstanding example the case of the Autocar company may be taken. This concern produced its first truck with a horizontal engine, not under bonnet, in 1908 and it is still making a machine which follows the same general lines. The Autocar truck has a high reputation and the fact that the company has not abandoned their type of power plant is not due to conservatism, since they did experiment with the vertical four but returned to the original construction as preferable.

Again, with respect to transmissions, the planetary types which were abandoned one by one in favor of sliding gear transmissions had not had a tenth of the experience and knowledge put into them which has been given the sliding gear. The planetary transmission, all other things being equal, ought to be more durable than the sliding gearset. The sliding gear is easier to make right. Is it not probable that this is why it is the commonest type to-day? At the present moment the speed change mechanism is regarded as the weakest point in the passenger car. For really efficient operation it calls for considerable skill on the part of the driver. It is noisy, the gears require occasional replacement and there is a quite perceptible drop in efficiency when the indirect ratios are in use. These facts have led passenger car engineers to produce cars with enormously more engine power than is necessary for the work they have to do. Interest in electrical variable speed transmissions is growing very steadily, if not very rapidly, and that the passenger car industry will try out various forms of electrical transmission on a large scale is now assured. It may be next year, it may be the year following, it may not be for 4 years, but the electric transmission year is coming just as surely as the six-cylinder engine was coming in 1911.

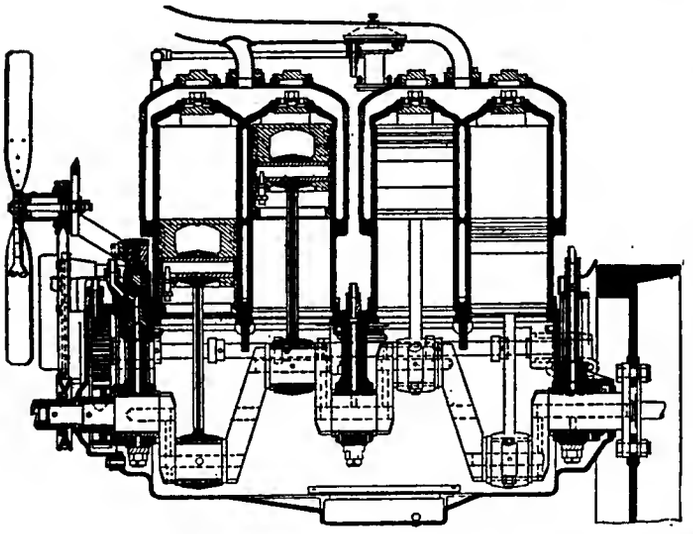
If this happens, what is going to be the reaction on the design of trucks? If the passenger car trade still largely controlled the truck industry it would be natural to assume that any really vital change in passenger car engineering would be followed by a corresponding change in truck design. But it appears now as likely that the big producers of trucks will be truck makers exclusively. It seems more likely that the successful firm making both trucks and passenger cars will split its business into two separate organizations than is it probable that more passenger car makers will enter the commercial vehicle industry. Furthermore, we are now training a large number of truck engineers and in a few years' time there will be hundreds of men who commenced their automobile career in the commercial field, who have never had any passenger car experience, and the effect of this is bound to be noticeable.

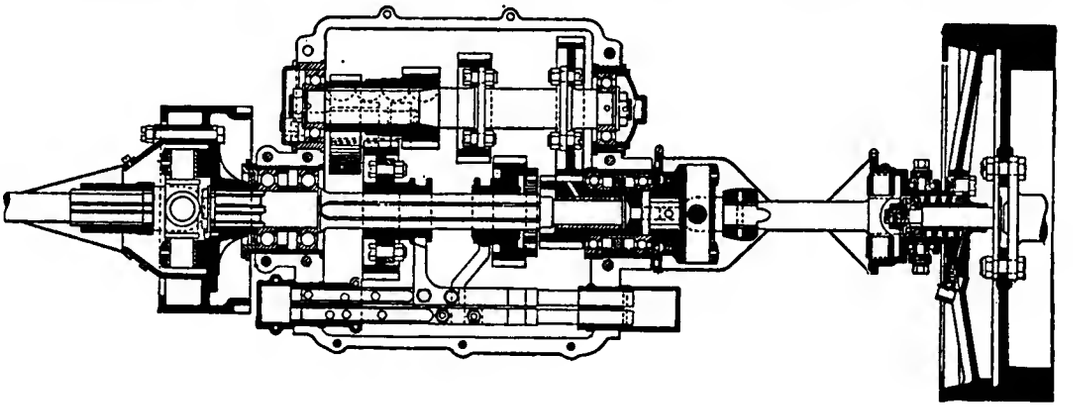
Truck and Car Essentially Different

For one thing it is already quite obvious that there are essential differences between the passenger car engine and the truck engine. They are tending at the moment to grow more different rather than more alike. The majority of truck engines to-day work at their maximum power for a large proportion of the time they are in use, whereas the passenger engine but rarely does this. Consequently, the truck engine needs larger bearings in proportion to the internal stresses at maximum horsepower, its cooling requires to be, if anything, more thorough, and all parts of the engine must be proportioned to resist shocks which need not be allowed for in designing passenger car engines. Again, fuel and oil efficiency are vital factors with a truck engine whereas they are secondary to smoothness and quietness in a passenger car power unit.

It is almost possible to sum up the situation briefly by saying that the truck industry is developing the large, highly efficient four-cylinder engine simultaneously with the abandonment of this type by the passenger car industry.

Turning to transmissions there is very little demand in the pleasure car field for anything except three-speed gearsets of comparatively cheap construction and this is because the bulk of the running is done on high gear. This is not true





The engine and transmission of the first Pierce-Arrow 5-ton truck introduced in 1910-1911. This machine was a combination of American and British practice, the engine being almost entirely American

of a truck and it is only recently that entirely satisfactory gearboxes for trucks have been purchasable as stock parts. Here again difference in ideals is apparent. In a passenger car gearset quietness is much desired. In a truck efficiency, long life and ease of gear shifting all come far ahead of quietness in the list of desired qualities. It is easy to make a good passenger car gearset because the passenger car transmission is used only occasionally. With a truck it is difficult because the transmission is in use for a large proportion of the time.

Of course, when we come to the final drive the truck has always been essentially different from a passenger vehicle. As soon as chains were abandoned on passenger cars and the bevel driven rear axle replaced then it was obvious that the truck of the future would have a different final drive. As long as we continue to use road wheels between 30 and 40 in. diameter it will be impossible to use a rear axle for heavy vehicles with a single bevel gear reduction, solely because of the available space and the great gear reduction required.

Enter the Worm

The rapid development of final drives alternative to the chain dates from the introduction of the worm drive in the Pierce-Arrow in 1911 so far as American engineering is concerned. Of course there had been plenty of rear axle constructions in use before that time, but it was the action of the Pierce company in adopting the worm which really started the great general movement away from the chain. Here again it is extremely difficult to discover the true reasons for various obvious facts. The chain drive, if laid out properly, if chains are good and particularly if the chains are inclosed, has many advantages not possessed by any other form of rear axle drive. The worm axle, the internal gear axle and the double reduction type all have special points in their favor. They are alternative methods of arriving at the same end. On the whole, it is less surprising that we should have four different forms of final drive all giving much the same result than that we should have many more than 400 different kinds of carbureter between one and another of which there is very little to choose.

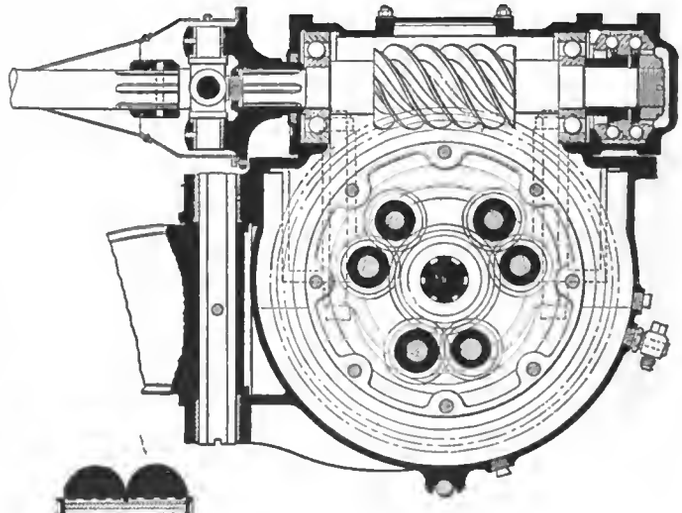
The important fact, however, which it is desired to emphasize, is that whatever the ultimate answer may be with the final drive problem it has got to be worked out by truck engineers, and the passenger car industry can give no help whatever.

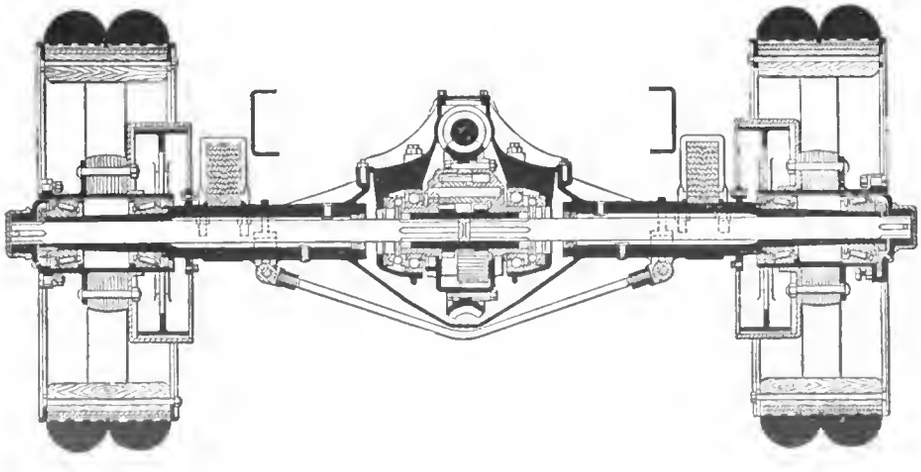
In a sense it may be said that this question of final drive is the first problem the truck industry has had to decide for itself. Previously it has always been able to look for assistance from the accumulated experience of the passenger car manufacturers. Some people occasionally voice surprise at the extraordinary vehemence of the protagonists of the various forms of final drive now being used in trucks, expressing wonder that we have not seen the same situation with regard to the position of the engine, the number of cylinders and every other point of truck construction which has been debatable in the past. The explanation most probably is that a young industry is very much like a young man and is extremely positive when it makes any assertion. The final drive is the first highly debatable subject which has arisen since the truck industry existed as a strong and healthy individual, since it was freed from the apron strings of the passenger car.

Final Drive Petty Question

Actually the question of final drive is one of the least important which the truck industry has to face. Efficient transmission between the engine and the rear axle is far more important, the economic value of trailers is perhaps more important still, while the utilization of fuels cheaper than gasoline is so much the greatest problem that all others sink into insignificance beside it.

To use the oldest metaphor, to argue about the detail design of rear axles is a magnificent instance of the tendency of men to fiddle while Rome burns. It is a fact that the electric power situation interests anticipate a greatly increased use of electric vehicles as a result of price of gasoline. It is also a fact that it is perfectly practical and possible to run engines on fuel far less refined than gasoline. Even though the price of gasoline may fall again it seems incontestable that something a little heavier must always be cheaper than gasoline itself. The automobile industry throughout the world has refused to face the problem of fuel supply right up to the present year but that it has to be faced now is at last realized and work is commenced which ought to have been begun 10 years ago. The user of a passenger car reckons his fuel bill as important, although actually it is but a small proportion of his total expenditure. To the truck user the fuel cost is *vitally* important, so important that the user will find means to employ some cheap fuel even if the manufacturer neglects to tackle the question.





The first 5-ton Pierce-Arrow truck axle with worm drive. This was a purely British design and the worms were at first imported from England but later made here

At the present time there are actually on the market, or about to come upon it, all kinds of devices for utilizing kerosene in engines designed to operate gasoline. Like most specialities of this sort put out by irresponsible people with no reputation to lose, a majority of these heavy fuel devices are of negligible value. The most extravagant claims are made for them, they will be sold in fairly large quantities and they will encourage in the truck user a belief that the successful burning of kerosene in a truck engine is impossible. Perhaps of all the special vaporizers just two or three will give good results. For the *industry* to find out which two or three deserve notice would not be difficult, would not take long, would not call for much expenditure of money. The *private user* will never find out except by happy accident. If 2 per cent of the kerosene-burning attachments advertised are really capable of doing the work claimed for them, this means that 98 per cent of private purchasers of kerosene vaporizers will be disappointed.

The industry, if it likes to take the trouble by finding out which is a good kerosene carbureter and then fitting it as stock or as alternative stock on its trucks, could go far toward reversing these percentages, changing the proportion of satisfied truck users from 2 to 98 per cent.

Another matter which is pure engineering and yet one which hardly any truck engineers having opinions on, is the question of what should determine the width of tire. There is no really good rule for determining the width as to the most economical method of tiring a truck. Some claim that very large tires will have an enormous life and therefore be the best. Others say it is better to use smaller tires and renew them frequently. This is the kind of thing which ought not to be a matter of opinion. It is simply a question of fact and to prove the case needs merely the collection of sufficient data.

Spring Suspension Faulty

Quite a different matter, which is an example of a surprising neglect of an opportunity for ingenious engineering, is to be found in the spring suspension. It is recognized that a truck is more easily damaged by being run light than run loaded. If a truck has springs which are correct for the loaded weight they are bound to be so stiff when unloaded that they become practically solid bars of steel. If we had only the two cases of full load and no load there would be reason enough for endeavor to improve upon the system of springs. But when we remember that the truck must frequently operate in a half loaded condition the importance of spring design becomes even more obvious.

For the sake of the goods which the truck is carrying, if these are of a fragile nature, and for the sake of the truck itself at all times, it is vitally important that the spring should be just right for the load whatever the load may be within the limits of no load and maximum load. Many engineers have evolved systems which will increase the stiffness of the spring automatically as the load increases but these men are usually looked upon as cranks.

Here, undoubtedly, the passenger car is exercising a vicious influence. On a passenger car a fixed spring is satisfactory, but this is no more reason why it should be satisfactory on a truck than does the suitability of beefsteak as an article of human diet prove its suitability for horse feed.

Possibly these strictures on present-day truck engineering may be thought needlessly severe. If this should be the case let it be remembered that the truck as applied to the service of industry is only just emerging from the experimental stage. It is only within the last 2 years that the public of the business world has realized the truck has come to stay. Three years ago the majority of business men in America would have bought horses and wagons with possibly just a passing thought about the truck. If the truck salesman happened to catch them just at the psychological moment the deal was sometimes engineered. To-day the situation is entirely changed, and a man who has goods to transport thinks of the motor truck first of all. We are reaching the stage where the question to be answered is more *which* motor truck than *whether* a motor truck. Before the passenger car had reached the stage of reasonable reliability and efficiency many hundreds of thousands were in the hands of private users. It was the accumulated experience of the individual owner which changed the passenger car from what it was in 1906 to what it was in 1912. It was in the trouble department of the factories that the engineers were able to discover wherein their designs were wrong.

Looking back through the years you can see some of the big things which were done in those 6 years. First, axle breakage was practically ended, spring breakage was very much reduced and last, if not least, the drawback of hand cranking was abolished. To-day we realize that to expect the owner to continually indulge in the athletic performance of cranking his engine was ridiculous, but one would have hesitated in 1906 to say that the absence of a self-starter was an absurdity.

Particular Problems of Truck Engineering

The truck industry has only just been given the opportunity of waking up to the peculiar particular problems which concern it vitally and have nothing whatever to do with the passenger car, and one of these is variable spring suspension. There is nothing so risky as prophecy, but there are just three things in truck engineering which seem bound to come:

One is the variable springing just mentioned.

Another is the use of cheap fuels.

The third is an improvement in the transmission system so that a wider range of variation is obtainable with even less skilled operators.

The four-cylinder engine does its work so well that there is little reason to anticipate any early change with regard to the power unit.

In frame design we may see still greater care, for flexibility we may see something like a three-point suspension for the body on the chassis or we may see flexible bodies which will weave with the frame.

A little detail which is coming, and not before it is needed, is a better protection for the driver. A high dashboard with a cowl excluding side doors and even windshield are things which tend to increase the comfort of the operator and therefore increase his efficiency. The cost is very small and there is no reason save custom why they should not be provided.

Of the debatable points in truck futures none stands forth more prominently than the trailer. Is it a real advantage or will it prove an economio mistake on a large scale? Manufacturers and users are divided on the question just now, but it will only take a year or two to prove the issue. Almost certainly we shall find that trailers pay under some conditions and do not do so under others. There is a chance here, though, that we shall make a discovery that may not be altogether anticipated, and this is that there is a real field in ordinary commerce for some form of road train.

The road train has hitherto usually been too complicated and too costly to permit it to be tried out on a large scale, and no small scale experiment can prove anything very much, but road trains could be built much simpler, especially gas-electric road trains. In Europe development is continuing steadily, which means that data are being collected and that we may one day wake up to find the road train a factor to be reckoned with. On the other hand it may die out in competition with the tractor and plain trailers. The thought just now is that the situation ought to be watched carefully; the truck is breaking away from the passenger car in engineering as in many other things and no man yet can tell how wide a breach the future is to show.

1916 Output 98,000 Trucks

58,000 Built in First 6 Months of Year—116,000 Predicted for 1917—Better Manufacturing Methods Overcome Increased Materials Cost and Higher Wages

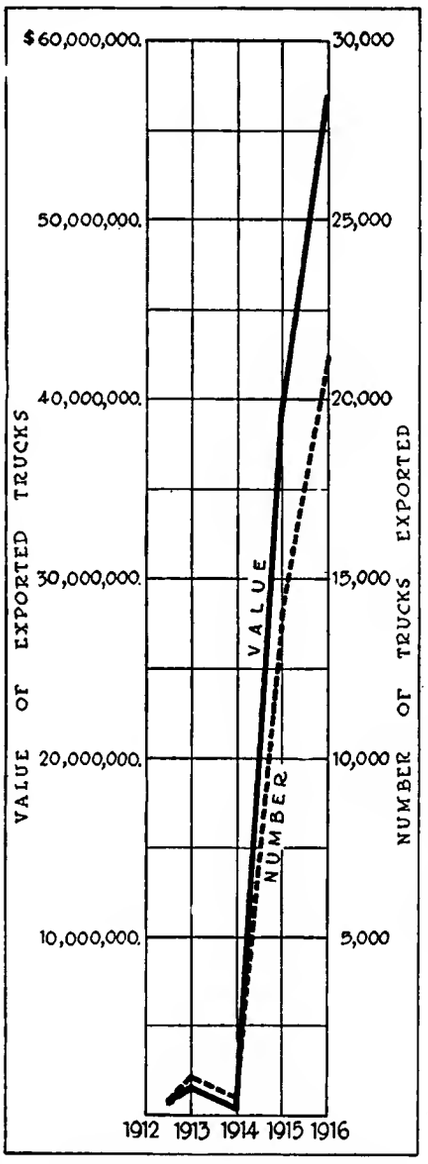
By Donald McLeod Lay

ALL production records in the history of the American motor truck industry will be shattered by the output of 1916, a total of 98,000 commercial vehicles being scheduled for the year. Of these approximately 58,000 were built during the 6 months covering the period from Jan. 1 to July 1. As compared with the number of trucks built in 1915, the current year will show an increase of 25,000, the total for the 12 months preceding Jan. 1, 1916 being 74,000 vehicles. For 1917, still greater expansion is promised, an estimate for the total output based on data furnished by the manufacturers being 116,000 machines.

In contrast with the big development of the motor truck industry in 1915, when production more than doubled over that of the previous year, jumping from 35,000 to 74,000, war business has played a decreasing part in the still greater volume of business which characterizes 1916. Although thousands of trucks are still pouring from our factories in response to orders from the belligerent governments of Europe, our manufacturers have realized that this business is at best merely temporary and are bending their efforts to widening the domestic field and building up new markets for export. And as war orders are being completed, production does not decline throughout the industry as a whole because the enlarged requirements of the business men of the United States and other countries keep the factories working at top speed. Unlike the war order business, this increased demand means permanent benefit to the manufacturers and practically all of them realize this fact. This is one reason why the estimate of motor truck production for 1917 is nearly 20,000 higher than that for the present year and it must not be forgotten that war orders are not reckoned as a factor in the business of the coming year.

From data furnished by the manufacturers approximately 50 per cent, or 49,000, of the 98,000 trucks, to be built during 1916, will be of 1500-lb. capacity or under; 25 per cent, or 24,500, will be of the 1, 1½ and 2-ton types; 20 per cent, or 19,600, will be of 3 and 3½-ton capacity; and the remaining 5 per cent, or 4900, will be vehicles of 5-ton capacity and over.

The field for the light delivery vehicle has been considerably widened this year by the introduction of numerous devices and attachments for converting Ford chassis into machines of this type. There has been a normal proportion of increase in the demand for practically all the various capacities, although the large numbers of the vehicles of medium capacity ordered for military purposes in Europe and by the United States Government for service on the Mexican border have greatly increased the production of these types. It must not be overlooked, however, that another cause for the striking acceleration in the manufacture of light delivery cars is the tremendous development of its field in the small towns and semi-rural communities where the grocers, butchers, dry goods stores, plumbers, and others have at length awakened to the possibilities of broadening their businesses by means of these machines. This year has also seen remarkable progress in the adaptation of the heavy commercial vehicles to numerous branches of industry, contractors, lumbermen, road builders and others finding these types of enormous value both as time and labor savers.



Number and value of motor trucks exported in the past 5 years

While the motor truck industry profited considerably by the European war, which not only increased the demand for commercial vehicles for war purposes but also opened new avenues of trade in the export field, the high materials prices caused by the conflict constituted the most serious hindrance to the increase of production during the year. When it is considered that malleable iron is 33 1/3 per cent higher than before the war, steel bars 40 per cent higher and alloy steel 100 per cent higher, it is no wonder that a number of our manufacturers have been obliged to increase the prices of their vehicles. Nor are the materials mentioned the only ones which are used in motor truck construction that have been increased in price due to war conditions. Among others may be mentioned cold roll steel 60 per cent higher in price than in normal times, forging billets 90 per cent, carbureters and brass work 25 per cent each and woodwork 20 per cent. Leather is much higher, aluminus more than double its previous price and many other materials which are used directly or indirectly cost the manufacturer far more than was formerly the case. In addition to the increased cost of materials the motor truck manufacturer has had to contend with labor difficulties due to demands for higher wages, shortage of skilled mechanics and factory workers

and higher costs of transportation. Improved manufacturing methods such as systematic layout of plants, progressive assembly methods, better equipment and higher general efficiency have enabled the truck builders to successfully overcome the difficulties presented by higher production expense in almost every instance and it is solely due to the development of these factors that the prices of motor trucks of all types have not been considerably advanced. Moreover it is the continued use and more advantageous adaptation of these methods which will enable the American commercial vehicle manufacturer to compete with the European product in the export field after the war is over. From the reports of the progress made during 1916 in the direction of reducing expense of manufacture another feature which promises to be of value in this connection is the policy of many companies to produce as much as possible of each vehicle in their own plants. A number of parts which were formerly purchased outside are now manufactured at much lower cost, thus doing away with not only the additional expense necessarily entailed by having them made in another plant, but also with the cost of transportation and frequently of unpacking, handling, etc.

In keeping with the more settled character of the industry, the manufacturc of motor trucks is getting away from the seasonal activity which characterized its early years. Demand is of course not yet entirely coordinated with production, but it is much more uniform throughout the year than was formerly the case and indications are that a steady improvement will take place from year to year. July and August seem to be the only months when the truck factories show any tendency to slacken the pace of production and even at this time of year they are far from idle, many of them being obliged to work night and day to keep up with their orders.

Refinancing to provide for factory and general business expansion has not as yet become as general in the motor truck industry as with the passenger car builders, but during 1916 several large companies have been obliged to expand their plants so rapidly and to such an extent that additional working capital was imperative. Entire new factories have been built this year and factory additions costing millions of dollars have been erected and others are still under construction, machinery and other plant equipment has been ordered in prodigious quantities and yet the working forces of the various factories have been only slightly increased, showing that better manufacturing methods and improved facilities have played an important part in this year's record. As an example of the heightened efficiency which is typical of truck factory operation, twenty-three of the leading manufacturers reported an increase in production for the year just double the increase in the number of men employed.

The increased difficulty of obtaining materials had a marked influence in holding up deliveries of trucks from the factory as well as interfering with production schedules, frequently making it impossible to run a plant on an even basis. Gear-sets and shafts, alloy steels, aluminum forgings, wood, tires

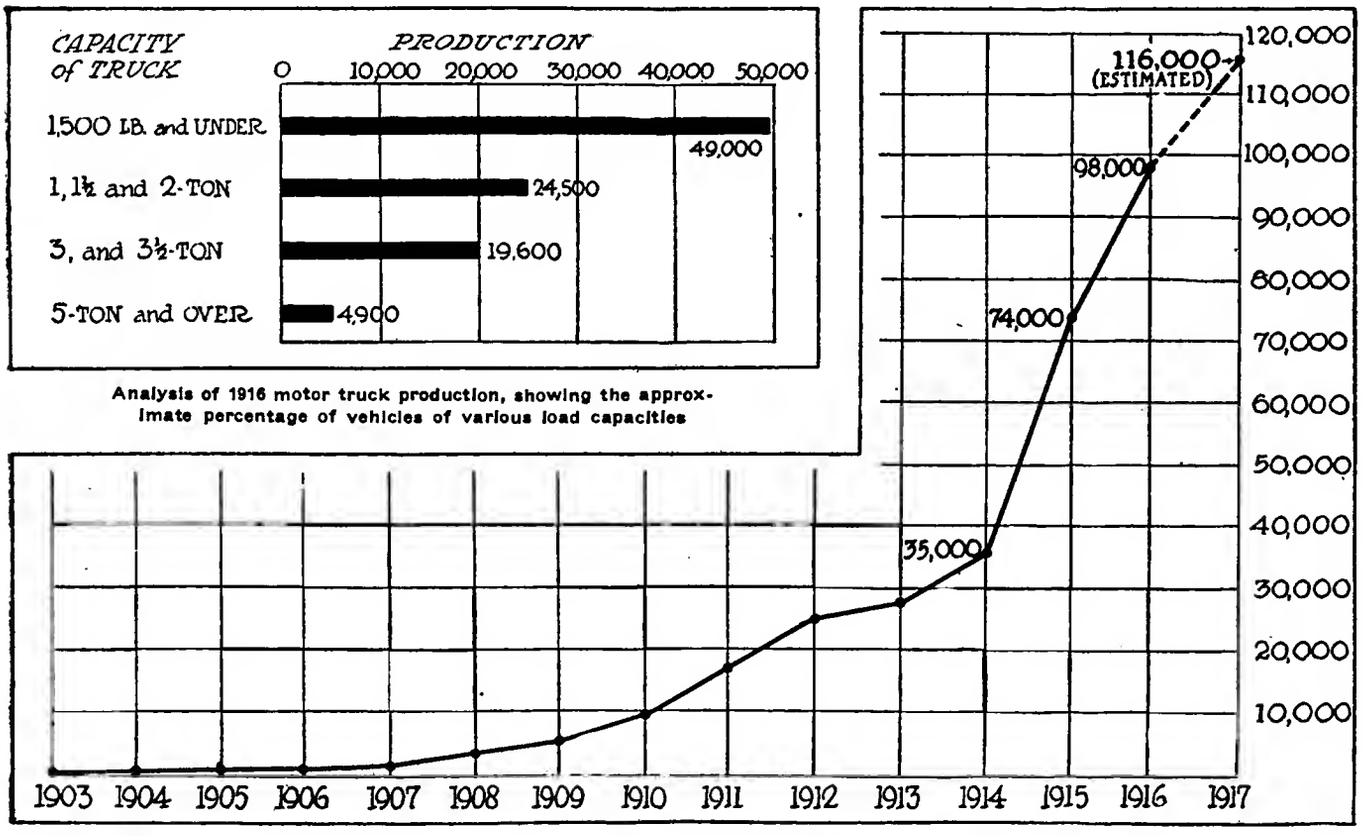
Analysis of 1916 motor truck production, showing the approximate percentage of vehicles of various load capacities



Curve of motor truck production in the United States each year from 1906 to 1916, with an indicated estimate for 1917

Few Changes in Truck Design

Some Expected Developments Arrive But Others Fail to Appear —Light Delivery Machines More Ruggedly Constructed—Hint of Return to Right Steering—Electrical Equipment Gaining Fast

AN analysis of the alterations in truck design made from the specification tables published elsewhere in this issue indicate a settling down in design rather than much that is new. It shows that some tendencies observed a year ago have proved to be permanent, but it also shows that some things which threatened were not true indications. Summing up everything, it is possible to state positively that the main indication is that the engineering of the truck is getting more away from that of the passenger car.

It is especially to be observed that the lightest commercial vehicles are being produced as purely truck designs, although a majority may still be passenger car chassis, which is due to the fact that delivery vehicles are never called upon to sustain such high speeds as are demanded for passenger cars while they are required to cover very much more ground in a day. Ruggedness and greater weight are, therefore, much to be desired for delivery vehicles which are to see severe service.

Two years ago, the 1000-lb. truck was much in the public favor and a great number were built. Some of them were very light and were designed for package work where the weight of the load was a negligible factor and cheapness and speed were the prime requisites. Others were very elaborate and were designed for the severest sort of service, including overloading.

Experience has shown that many of these were used for ¾-ton loads and that their owners preferred them to 1500-lb. cars because they were lighter and cheaper to operate. This has resulted in minor changes in the design of many of these to adapt them to 1500-lb. loads with a corresponding increase in their capacity ratings.

Overloading Less Habitual

Somewhat the same change is noticeable all through the range of capacities, accountable largely to the fact that owners are a little less prone to overloading their vehicles, having learned from experience. Dealers are learning to gage the requirements of buyers better and to recommend fearlessly trucks of ample capacity instead of claiming unreasonable overload capacity for their wares. Manufacturers are building more intermediate capacities so that the owner is not tempted to choose the smaller of two trucks for a load midway between their capacities.

In the design of trucks there have been several contradictory tendencies. For example, after a three-year period during which the left-steering-wheel position came into prominence and bade fair to oust the right drive entirely, this rapid progress has been stayed and a smaller percentage of trucks have left drive for 1917 than was the case for 1916.

Among those who have forsaken left steer either throughout their lines or on their newer models are the makers of the Chase, the Koehler, Krebs, Little Giant, Selden, U. S., Universal and Watson.

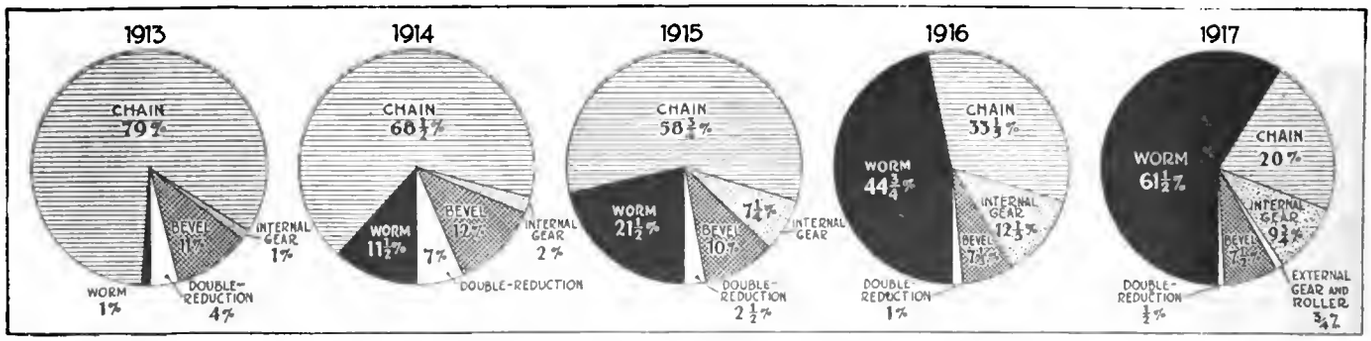
This condition has been influenced to some extent by European orders, which, of course, require right steering, but there has been a well defined insistence on the part of American buyers in some classes for right steering. This is especially the case with those who operate their trucks on country roads, since it is very difficult for the driver of a left-steered truck to determine how closely he may approach the ditch on the right side, and with the present prevalent narrowness of improved country roads and the concealed ditches this argument becomes a weighty one.

Frames More Flexible

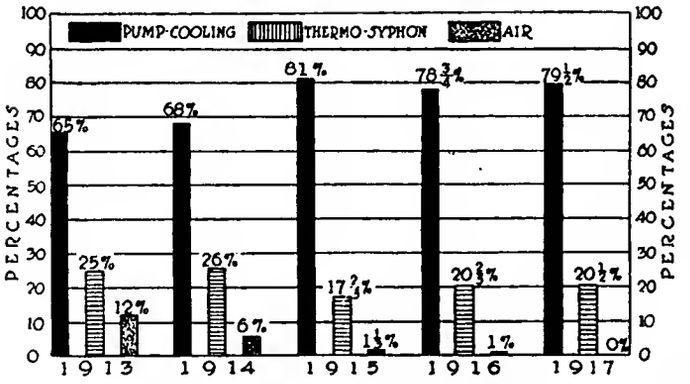
The improvement of truck design has extended even to the framework. In former years few gave any special thought to the frame of a motor truck, deeming that its office was to be strong enough to carry the load and stiff enough to keep the parts in their proper relation. Lately, however, the advantages of the flexible type of construction have been realized to a greater extent, and while many makers still adhere to rigid construction, relying on the springs entirely for compensation for axle movement, there is an increasing number who are adopting the flexible forms. The majority of makers are using what may be termed the semi-flexible form of frame, usually of pressed steel and yielding to severe stresses while remaining stiff against minor ones.

The steel wheel is once more in evidence, this time in a fewer number of forms, the cast type predominating. Doubtless the difficulty of getting wood wheels for part of the time this year has had its influence, but it is safe to predict a growing application of steel wheels to the heavier capacities.

Federal, Gramm-Bernstein, Knox, Republic, Walter and Zeitler & Lamson trucks have recently had steel wheels substituted for wooden ones as standard construction.



Diagrams showing decline of chain drive and rise of worm. Internal gear seems to have replaced the double reduction type meanwhile, and the plain bevel is dying out



Fluctuations in Cooling System Design

In wood wheels, the square spoke is the most popular type, since it affords a wider bearing on the felloe and is actually cheaper to manufacture than the older oval type.

The dual tire, after being outnumbered by the single, on the rear wheel, in the year 1915, has regained its advantage in the 1917 models. This is hard to account for, but no doubt is due to popular prejudice against wide single tires. The single rear tire, however, is gaining, nevertheless, in a way that does not show itself in the tables. Users of trucks all over the country are replacing dual tires with singles and many of the manufacturers who provide dual tires as standard equipment find many users who are willing to pay a slight additional charge for single-tire equipment all around.

Failure of more manufacturers to put large pneumatics on trucks from 1 ton upward is disappointing, although with the great activity and favorable opinion on the part of many of the tire makers there are good grounds for the expectation that before 1918 a number of models of 1½- and 2-ton capacity will appear with pneumatic equipment.

Electric Lighting and Starting Increases

A development which has been long in coming but which may be said to be with us to-day is the provision of automatic starting means for the truck and of electric lights. This comes as an expected development, if not one somewhat overdue. Formerly electric lighting and starting was principally confined to the lighter vehicles, but for 1917, out of thirty-eight manufacturers fitting electric lighting or starting and lighting systems as stock equipment, more than half are of medium to heavy capacity.

Automatic spark advance which it seemed at one time would become prevalent has not progressed of late, due probably to its cost, although appliances of lower cost are being developed. It would also seem a simple matter to use the same centrifugal governor which most trucks use to control the engine speed to take on the extra duty of advancing the spark.

That both hand advance and fixed-spark systems continue to have strong adherents seems to show that each has advantages not possessed by the other, and only combined in the automatic system. The hand advance permits greater economy of fuel if properly handled, than the fixed spark does, and permits the engine to pull better in difficult going. The fixed spark, however, is fool-proof and does not subject the engine to the wasteful abuse incident to improper handling of a hand-spark advance.

Hotchkiss drive has been steadily coming and to-day it is in the majority. There are a number of makers who use Hotchkiss drive, even on 5-ton and 6-ton trucks; but in the majority of instances its use is confined to trucks of medium capacity. This is because the thrust or propulsive duty on the spring assumes such great proportions in a heavy truck that nothing but the best type of spring with especially large and rugged pinning at the driving end can give satisfaction. During the year, several makers have removed radius rods from some of their models, however, due, possibly, to a better understanding of requirements for Hotchkiss drive.

Most of the new makes which have appeared during 1916 have had Hotchkiss drive in addition to which new models of the following makes, most of which formerly employed radius rods or torque members or both, have incorporated drive through the springs: Commerce, Dart, Hurlburt, Jeffery, Kisselkar, Little Giant, Moreland, Old Reliable, Republic, Royal, Selden, Stegeman, Stewart, Tiffin and Wilcox.

Associated with this trend has been development in regard to driveshafts. It has been the ideal of many designers for some time to reduce the truck chassis to the same simplicity which is noticeable in the newer designs of passenger cars, by means of unit power plant grouping of the engine, clutch and gearset and final drive by a single shaft with two universals.

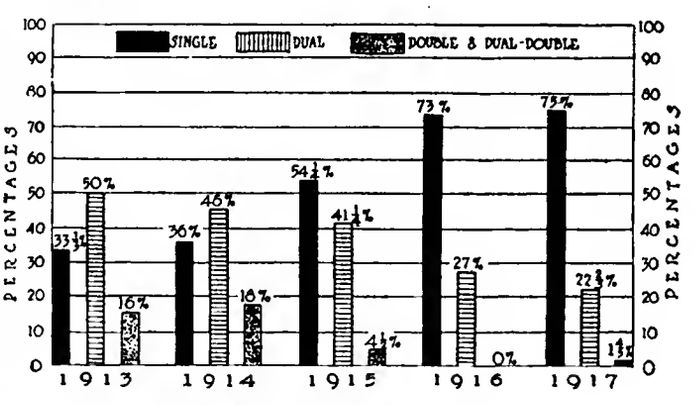
Difficulties, however, have been encountered in the excessive length of such driveshafts due to the long wheelbases possessed by the medium to larger trucks. Passenger car methods cannot be pursued here as small, solid shafts of such length are prone to whip and whirl, rapidly playing havoc with the universals, axle bearings and gearbox bearings. Accordingly much experimenting has been done with shafts made of large-diameter tubing, which with greater strength and little if any greater weight, are much stiffer than solid shafts. Remarkably good results have been achieved on wheelbases of considerable length, but for the longest wheelbases it has so far been imperative that the shaft be cut into two lengths with a stationary bearing between the sections.

Divide Propeller Shaft

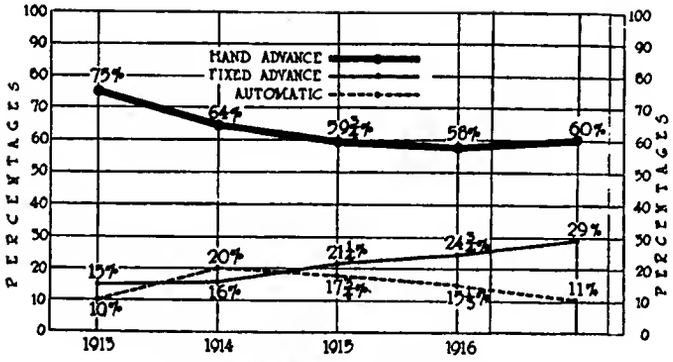
Some makers have provided this bearing at about the middle of a two-part shaft, others splitting the shaft by interposing the gearbox between its two sections. This latter practice has given rise to a decrease in unit powerplant assemblies and increased the percentage of makers who locate their gearsets amidships. Some of these, who have recently brought out new models with amidships gearsets where formerly they favored unit powerplant assembly are: Old Reliable, signal, Wilcox, Dayton and Diamond-T.

The disinclination of the American operator to shift gears more often than avoidable is reflected in the failure of the four-speed gearset to make more progress. It has, in fact, lost slightly in favor of the three-speed, despite the recognized fact that four-speed gearsets give the truck greater ability in difficult going and particularly in hilly country.

Somewhat of the same effect has been accomplished, however, by a slight increase in the size of engines and slightly greater gear reduction. More of the makers than ever are fitting governors, their undoubted tendency to restrict power on the lower speeds being avoided in an increasing number of cases by controlling from the driveshaft instead of the engine or by using the combination drive from both the engine and driveshaft.



Steady gain in single ignition



Hand advance still usual spark control

For example, Armleder, Old Reliable and Service models which formerly did not have governors, have for 1917 been equipped with the driveshaft-driven type. The Couple-Gear and Studebaker, formerly without governors, are now provided with the front-wheel driven type. New models of the Commerce, Globe, Old Reliable and Denmo have driveshaft-driven forms and duplex-driven governors have been adopted recently by Old Reliable, Thomas and Zeitler & Lamson.

During 1916, however, the situation in both the material and labor markets has resulted in sharp increases in the production costs of motor trucks. Prices have not increased in anything like equal proportion with the increased cost of material and labor, in fact, not even in proportion to actual production costs.

Production costs also have not increased as much as costs of material and labor for the reason that with increased production most of the factories have been able to use both more effectively, and particularly labor, and, with a greater output, in many cases with very little increase in overhead, they have been able to afford a smaller margin of profit on each truck, with increased gross earnings notwithstanding.

The range of models of motor trucks continues about as it has been for years past except that there are more of the intermediate capacities, while the average capacity of models produced remains about 2½ tons, as it has been for several years.

In the range of models from less than ½ ton up to 7½ tons and tractors, there is a definite division into two classes, the first being the delivery vehicle class and the second the heavy-duty truck.

The former embraces capacities up to and partially including the 1-tonner and the latter begins with the ¾-tonner and goes up. Production of delivery chassis outnumbers that of trucks two to one, and of the heavier trucks, those which might fall into a medium class, that is, from ¾ to 2 tons, represent a number equal to all of the balance, including tractors.

Light Chassis Means Quantity Production

Hence it is plain that the light chassis business is one of quantity production, and it is easy to understand why 50 per cent of the vehicles are built by 10 per cent of the producers. Delivery vehicles are usually mounted on pneumatic tires, each year witnessing a lesser percentage of chassis in this class equipped with solids. This is because only with pneumatic tires is it possible to run a vehicle at high-delivery speeds, without rapid tire and mechanical depreciation.

Capacities change but little year by year, due to the necessary conservatism in making radical changes in this respect, but a survey of developments in the last 5 years shows that the greatest gains have been made in two intermediate models, the 2½-tonner, a comparatively recent development, and the 3½-tonner which has been gaining steadily for years. The 3-tonner and the ¾-tonner have been losing steadily, since these capacities were set arbitrarily by manufacturers before the industry had built sufficient trucks really to know what was demanded.

The price change this year has only amounted to an average of $137, most of the models being increased but little. It is the trucks of less than ½-ton and of ¾-ton capacity whose prices have undergone the greatest increases because of the abandonment of many antique designs in these capacities in the face of the popular demand for better quality and stamina in the low capacities. These trucks average much higher, but they are also immeasurably better vehicles than were formerly offered, and to-day one may buy a truck of ½- or ¾-ton capacity which will give the same reliable and enduring service as the best of the heavy trucks.

That it has principally been the small to medium assembler who has been obliged to increase his prices is an instructive phase of the situation. This is undoubtedly because the large manufacturers, building a considerable percentage of their trucks in their own plants, such as Packard, Pierce-Arrow, Peerless, Riker and White have been able to secure raw materials sufficiently in advance to prevent any serious shortage, and, making their own parts, have not been affected by the shortage of some of the components occasioned by labor troubles in the plants of parts manufacturers.

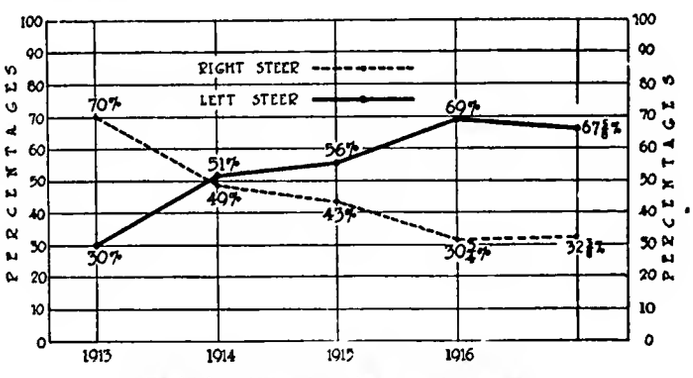
Large Producers Less Affected

The large assemblers have also in most cases escaped serious curtailment of production or delay of deliveries because their orders were of such size as to give them precedence over smaller concerns in the parts markets. Not all the big assemblers have had this good fortune, however, and some have found the supplies of parts too precarious for comfort.

As a possible avoidance of this danger, a few have undertaken to do more manufacturing in their own plants and even the smaller builders have installed more machinery for the simpler machining operations instead of having this work done outside on contract.

It may be questioned whether this is a permanent state of affairs, for the supply difficulty cannot be more than temporary; yet it is argued that a manufacturer of trucks who is equipped for the production of a good many parts is in a stronger position than one who does nothing except assemble his vehicles.

It seems unlikely that the ultimate situation will be an exact parallel of conditions in the passenger car trade, at least not for some years to come. It is going to take a good long time for the parts makers to develop their truck business to vie with their passenger car trade, and design being less fixed makes it harder for them to supply the precise needs of the moment. Thus we see instances of motor truck firms exerting their influence upon the design of the parts they buy. Some have designed engines which they are now having made for them; others have their own ideas in rear axles or universals and so on. Probably this means that the truck manufacturer is doing his best to help the parts maker and this cannot be otherwise than to their mutual advantage.



Right hand steering shows an increase

British Favor Gasoline Tractor

Experiments Being Made in England are Encouraging—Need for Cheap Machines After War

AMERICAN farmers are liable to look upon the diminutive farm of England as more like a garden than a real producer of crops, and to some extent they are right. Still cultivation in England has never been what it might be and there is a great change coming. During the past summer a paper on tractor farming was read by C. B. Fisher before the agricultural section of the British Assn., a scientific body of an eminently practical nature. The following digest of this paper taken from *The Engineer*, London, shows that there is plenty of interest in the subject and suggests a good market for the less expensive American tractors after the war. That there is a splendid market in France is already assured:

"The author claimed that motor traction had now got past the experimental stage, and the present need of the agriculturist was for advice as to the best types of machines to employ for particular cases. Comparisons of different tests under different circumstances on different soils, without further accurate information, both as regards the horse *vs.* mechanical power, of cable *vs.* tractor, or of various makes of machines, were practically worthless. In the first place, the variation of the dynamometer effort required to move different soils was enormous, and it was useless to compare a machine tested on a good soil, on which the pull required for a single-furrow plough, 9 in. wide and 5 in. deep, was approximately 500 lb., with another make of machine ploughing heavy clay, which required generally 1000 lb. pull, but which when really hard and dry would register 1200 lb., and would be heavy work for four horses to one plough.

Steam Plow Costs $15,000

"Equally important was the question of horsepower. Every maker stated the horsepower of his engine, and the intending purchaser compared the price and weight per horsepower of various makes of machines, and possibly the consumption of fuel per horsepower for work done, in order to arrive at their comparative value, but this was worse than useless in the absence of a uniform basis for calculation. It would be of great assistance if some uniform system of rating were adopted and insisted on by the Board of Agriculture for motor tractors. Care should also be taken to base calculations on equal prices for fuel and labor. The cost of a set of steam ploughing and cultivating tackle was about $15,000, and although the life of it was from 20 to 30 years, it was an outlay too heavy for the individual farmer.

"The author's personal experience had been acquired with a 20-brake-hp. universal tractor, made by Saunderson and Mills,* and the only appliance specially purchased to go with it was a three-furrow plough, all the others being the ordinary farm implements with the attachments altered. The duties to which the tractor was put were ploughing, threshing, and hauling. In ploughing three furrows the fuel consumption was 3 to 4 gal. of kerosene, 1 qt. of gasoline, and 3 pt. of lubricating oil to the acre. Threshing operations with a full-sized machine, with straw trusser attached, or the engine working the elevator, took approximately 2 gal. of kerosene an hour, 1 qt. of gasoline, and 3 pt. of lubricating oil per day, and the owners recently threshed one rick of oats, 66 quarters, in one day. The motor tractor showed a saving as compared with the ordinary method of threshing of 28 cents per quarter, and, in addition, it drew water. There would be a less saving when threshing wheat, but it might be taken at 12 cents a quarter. There was an enormous advantage in having the machine always ready when required, and only those who had formerly hired threshing machines could fully appreciate the benefit. The tractor had displaced horses for hauling. It would draw 5 tons at 5 m.p.h. on the road, doing three journeys, totaling 18 miles a day, on about 7 gal. of kerosene.

*A British machine.

Uses 1 Gallon per Acre

"The use of the tractor with self-binders was a striking illustration of its satisfactory employment. Two binders, which were easily pulled by the tractor, would call for the use of twelve horses for a full day's work. With the motor tractor and two binders up to 30 acres could be cut in a day, and the kerosene consumption was about 1 gal. per acre. The tractor had been used with equally satisfactory results for scuffling, rolling, and harrowing, and he had no doubt it could be used for drilling and mowing. He believed that Mr. Saunderson, the maker of the machine, had recently purchased a heavy clay land farm of 240 acres in Bedfordshire, which was being entirely operated by motor power, for experimental purposes. The full statistics were to be published shortly.

"With regard to the life of a high-speed engine employed on farm work, while much depended on the person who had charge, he would be inclined to base calculations for depreciation on a period of 6 years. He had referred to only one type, of which he had personal experience, but he believed that the value of other makes had been demonstrated. The motor ploughs in use were the Fowler-Wyles, the Wyles, the Martin, and the Crawley, which ranged in power from 10 to 30 hp. The tractors available were Weeks' Dungey Simplex, Big Bull, Mogul, Daimler, Universal, Sanduskey, Overtime, Ivel, Fairbanks Morse, Emerson and Omnitractor. The best known steam tractors were the Mann and the Ransome. He knew the users of some of the different makes, and in no case, under present circumstances, had they regretted their purchase. There was difficulty, however, in obtaining delivery, particularly of English machines.

Criticizes American Design

"British makers had made a particular study of the requirements of the agriculturist. One particular feature in which many of the American machines were lacking, was their unsuitability for haulage. He was personally in favor of a 20 to 25-brake-hp. engine for the farm machine. It should weigh from about 3920 lb. up to about 5600 lb., and should cost from $1,250 to $1,750. It should be fitted with three speeds forward and reverse. The motor tractor opened up possibilities of solving the question of reconverting the strong wheat land to its proper purpose, and thereby increasing the power of employment. It could and would raise the standard of wages by turning the agricultural laborer into a skilled mechanic. If the nation had decided that one of the chief lessons of the war was the necessity for a greater production of foodstuffs at home, the makers of motor tractors had a great opportunity of supplying the needs of the agriculturist. The farmer, before outlay of capital, would, however, require some stability in the price of wheat.

Military Truck a Complicated Problem

America Faces a Problem Quite Different from That of Any European Nation—Admixture of Engineering and Commercial Questions Makes Ultimate Solution Difficult to Forecast

By A. Ludlow Clayden

IN deciding originally upon its so-called "subsidy" specifications for motor trucks the British government called well known engineers into conference, and this plan is to be continued after the war in settling the future of military motor trucks.

There are two powerful organizations in England corresponding almost exactly to the S. A. E. and to the N. A. C. C., these being the Institution of Automobile Engineers and the Society of Motor Manufacturers and Traders. It has just been announced that all future research work relating to automobiles for government service of any kind will be taken care of by a committee having its membership made up mainly of representatives of the I. A. E. and the S. M. M. and T. with the addition of some officials directly appointed by the government.

It is common talk in England that this new committee will be started on its work before very long, and that its first task will be to draft specifications for military trucks down to the last cotter pin, determining the designs from the vast stores of experience gained in France and elsewhere during the past two years.

It is possible for a great military power to specify in this sort of way, to own huge fleets of vehicles and to hand out drawings to which manufacturers who want to contract may work; just as can be done with parts of guns or with shell and fuses, but there is a danger in adopting this system in that it may convert the military truck from a commercial article into a specialized one, which would make it just as hard to buy in large quantities suddenly as it has been for the Entente powers to buy munitions at home or abroad without immense delays while shops were being equipped for unaccustomed work.

America is not likely to become a military power within any time that need be considered at present, so whether or not a standard design of military truck down to the last nut is advisable for England, its advisability for America is very debatable indeed. An army suddenly faced with war has two desires in motor transportation. It wants as few types of truck as possible and would appreciate having only one design for each size, but it also wants quantities of trucks and wants them instantly.

Striking a Happy Mean

To get trucks in quantities without warning means that the regular product must be accepted, and this is just the situation the American army authorities had to face last summer when the call came to the Mexican border. France and England did the same thing in 1914, but since their governments have been taking nearly all the mechanical output of the two countries, it has been possible to concentrate manufacturers on special types. In Coventry to-day, for example, one automobile maker is now building chassis to the drawings of a rival firm, the latter having been ordered to produce only aeroplane engines for the time being.

It is the desire, and the very wise intention, of the United States army authorities to try to evolve a scheme which will eliminate the worst of the troubles and confusion from which they have suffered, without limiting the possible market so much that, in case of emergency, they could not obtain rapid delivery of large quantities. The Mexican experience has shown that certain things most vitally need to be standardized for interchangeability. Radiators, for example, however they may differ in detail construction, ought to fit all trucks of any one rated size. The mounting and the position of the water pipes should be absolutely limited, so that any radiator would go on any truck.

Of a different sort is the requirement that control should be standard, so that any driver would be at home on any truck, but this is almost as important, and there are scores of similar little things which can be standardized without limiting the engineering scope of any truck manufacturer.

The old British scheme was to specify just such things as these and to pay a small yearly sum to every user who bought and operated a truck with the standardized details, and most of the truck manufacturers of England found it paid to produce "subsidy type" vehicles. They found it easily possible to make these to designs which hardly appeared to have any similarity at a casual glance, and the standards were incorporated in trucks of all prices. When war came some of the standards proved good and some less desirable, but the scheme itself was vindicated, although it had not been in operation long enough for there to be any appreciable quantity of subsidy type trucks in existence by the outbreak of war.

Subsidy Not Wanted in America

The idea in granting the subsidy was to encourage the production of trucks acceptable to the army, but it may be questioned whether such encouragement is really necessary. If a manufacturer is not handicapped in any way by using specified dimensions for certain portions of his truck he would benefit the ordinary user by adopting them. We all know now that a truck with tires that are not standard size is an absurdity; we are accustomed to the use of a standard tread; the absence of a spark plug standard would produce incalculable trouble and so on.

Still there is a limit beyond which we cannot go without beginning to lose as much as we gain and the striking of a happy medium between too much standardization and not enough of it is a task which is going to tax the powers of many a committee in the next five or six years. The problem is one that will always be present, since improving knowledge will call for alterations in design and thereby every now and then we shall discover that some accepted standard has to be changed.

A military wagon can be designed with some reliance that it will be just as good 20 years hence as it is now, for there is little left to learn about horse-drawn vehicles, but motor truck specifications will have to be revised at least each third year, if the army is to keep itself supplied with the best obtainable for its purpose. This makes the situation quite complicated, and renders it very hard to steer the proper

course, but there is no question whatever that the U. S. army is proceeding along the right lines and that it will be as well served by the industry as it could possibly be as long as the present methods continue in use, and they are not likely to be altered very much.

The armies of the world have been slow to realize that the coming of motor transport has created an entirely novel situation. Previously everything which was needed by an army was either an entirely special product, such as guns and ammunition, or else an entirely ordinary one such as food, boots and clothing. When it comes to motor trucks, however, at the present time the army needs something a little different from the commercial product, but not so different that the making of it is an industry in itself as is the case of guns and munitions.

The statement that the military truck is to differ from the commercial is still debatable. It is quite possible that when definite conclusions have been reached as to what should be the specifications of a military vehicle we shall find it is also an excellent machine for the uses of commerce, but there is as yet no evidence which will enable this matter to be decided.

In England, at the outbreak of the war, the subsidy system had been in operation so short a time that there were only a few subsidy type vehicles in the hands of private users. The time elapsing between the delivery of the first few subsidy trucks and the date when they were called in for military service was too short to enable their suitability for commercial work to be gaged accurately. Since that time war service has shown that the subsidy vehicle is not necessarily ideal for military work.

In France, although there was a subsidy scheme it was not developed even so far as the British one. In Germany the total number of different makes of truck was very small, so that the effect of the German subsidy system was really to provide large fleets of a small number of designs. Thus we cannot find in Europe any parallel to America.

Military Truck a Complicated Problem

(*Continued from page* 751)

We have already gained a great deal of knowledge regarding the good and bad points in design from Europe and from the Mexican border. When more news comes from France and England we shall know still more than we do at present, but even then there are conditions in America which differ from any to be found in Europe, so whatever volume of information may come from across the Atlantic, America will still have to depend mainly upon her own engineers.

Years ago the Glidden Tours did much to take the conceit out of the passenger car engineering profession, as year after year they brought out weak spots in design. Until the last 2 years the motor truck had had no corresponding test, which means that truck engineers have never had any real large collection of data relating to tests to destruction. No one here can make much progress by relying entirely upon his own experience; or, putting it another way, the larger the amount of the experience upon which any engineer can draw the faster is his progress likely to be.

The military authorities have nearly 3000 trucks in use along the border and know the good, bad and indifferent features of each design and they are making analyses which will be a wonderful help in specifying the army requirements in the future. The engineers of the industry have access to much of this information and when told of a particular kind of failure they can probably get to the original cause of it quicker than any one else. It would be a wonderfully instructive thing to take six of the leading truck engineers and have them individually, and without co-operation, each design his ideal military truck. When the six machines were made and put in service it would certainly be found that each had its points of fitness and each had its weaknesses, while it is also certain that amalgamation of the virtues of the six into a seventh new design would produce a truck as near the ideal as anything the engineering profession can produce at present.

The Society of Automobile Engineers is trying to obtain the broad specifications for a hypothetical seventh truck in a quicker and perhaps an even more thorough manner.

In the truck industry there are many men whose vehicles have gone to the border and these men each know just what is wrong with his own particular designs; each of them has already formed an idea as to what he would design were he to build the machine solely for army work.

The S. A. E. believes it possible to amalgamate the knowledge of all these men, obtaining therefrom one ideal specification for a military truck which will stand better chance of being really correct than would the ideal of any one engineer alone. The method which has been adopted is to draft the specification which was published in THE AUTOMOBILE for Oct. 9, and discussing this original draft, in committee and by correspondence, detail by detail, it will soon be seen upon what points the engineers, as a whole, are agreed.

When a man is doubtful about his politics he talks to others, discovers their ideas and eventually makes up his mind; similarly the work the S. A. E. has set out to do is to make up the mind of the truck engineers as a body by facilitating discussion between the individual members thereof. Unofficially, the S. A. E. is going to obtain a great deal of assistance in this work from some of those who have had charge of the trucks on the border and who have, therefore, first-hand knowledge.

Technical Specifications of Gaso

Battery Service Widens

ONE of the most important developments in the electrical vehicle industry during the past year is the development of battery service systems, or as they are sometimes called, battery exchange systems. This has greatly widened the field of the electric truck and increased its efficiency in installations of one, two or three vehicles.

The system is based on the principle that it is more economical to maintain an electric truck as one of a fleet of many than as an individual vehicle. Various forms of the system are now in use in more than ten cities throughout the United States. The system's greater development in 1916 has proved one of the most far-reaching steps in the advancement of the electric truck industry during the year, and has increased the sales of trucks wherever introduced.

The larger use of battery service has occasioned a greater degree of co-operation between truck user, truck manufacturer and the central station interests who have supplied the current for the battery charging.

Detachable Battery Cradle

The system in brief consists of the purchase of an electric truckless battery, the vehicle being supplied with a specially-designed detachable battery cradle. By the use of this interchangeable cradle the company furnishing the power is enabled to exchange a discharged or partly-discharged battery for a fully-charged one in from 2 to 5 min.

The current used is sold by the mile, according to the size of the vehicle and the amount of mileage as recorded by the odometer. An additional fixed sum is charged for the battery service and inspection, and a third fixed charge if the vehicle is garaged at the point where the batteries are exchanged. Both of these latter charges are fixed for any particular size of vehicle, although of course they are graded according to the truck capacity and the rate for current decreases as the mileage increases.

For the user, the battery service system eliminates practically all of the objections which have formerly mitigated against the more general use of the electric as compared with the gasoline truck. These objections included: A high initial cost of vehicle; uncertainty in the small user's mind as to the efficiency and life of the battery and the trouble of its care and that of the charging apparatus necessary; the limited mileage on one charge of the battery and the uncertainty as to the actual cost of truck operation.

Electric Truck Scope

All of these objections have been overcome by the battery service plan in which the user does not buy, own or care for the batteries, but concerns himself only with the actual operation of the trucks. Without batteries the prices of the trucks are reduced anywhere from 20 to 38 per cent. In addition, the exchange battery feature of the system eliminates the limitations of battery mileage and enables the truck owner to operate his vehicle 24 hr. daily if he so desires by simply changing the batteries as fast as they become exhausted. As the charges for the battery service and inspection are fixed no matter how many batteries are used in a day and the charge for the current consumed, based on the mileage covered, the truck owner pays in exact proportion to what he receives. Furthermore, these charges can be ascertained easily and often determined in advance.

Finally, the system offers the purchaser a substantial reduction in truck investment in addition to the elimination of charging and garage apparatus. It also offers unlimited mileage and a reduction of all battery-care costs because of the savings effected in the handling of a large instead of a small number of batteries as would be the case were the truck owner to maintain his own batteries.

The advantages of the system to the truck maker are of course obvious in that it tends to increase the sales of trucks. The advantage to the central station supplying the current is that it offers a ready means of disposing of the off-peak current.

The system as outlined above is not new, the General Vehicle Co. and the Hartford Electric Light Co., Hartford, Conn., having inaugurated such a system as far back as June, 1912. Before that several department stores, mail transfer concerns, textile mills and others developed private battery exchange methods.

System Used in Many Cities

The General Vehicle Co.'s system, which is substantially that as outlined above, is now in operation in nine other cities besides Hartford, Conn., with several others pending. The cities in which vehicles are now being operated on the system include Spokane, Wash.; Boston, Mass.; Baltimore, Md.; Harrisburg, Pa.; San Francisco and Los Angeles, Cal.; Worcester and Fall River, Mass., and Wichita, Kan. In all, there are several hundred electric trucks now being operated on the Gevco or General Vehicle Co.'s system in these ten cities.

Aitken Wins Harkness Trophy Race

Peugeot Pilot Covers 100 Miles at 105.95 M. P. H., Breaking American Speedway Record—Pace 109 M. P. H., Until Resta Was Eliminated at 65 Miles

Start of the Harkness Trophy 100-mile race

Aitken at the wheel of his Peugeot after winning the Harkness Trophy race

NEW YORK CITY, Oct. 30—The old Brooklands record for 100 miles still hangs by a hair, rather to the surprise of the majority, who expected to see it beaten at Sheepshead Bay last Saturday. Actually Aitken on his Peugeot came within 7.52 sec. of the record time, and could have beaten it easily had he wished to do so, since he had been running easy from the time that his chief rival, Resta, was forced to retire, about the middle of the race.

As it was, Aitken knocked 47 sec. off his previous best time for 100 miles, made in the Astor Cup race 4 weeks ago, and worked himself back into the lead for the American speedway championship, Resta taking second place in the new ranking list..

The race was a Resta-Aitken duel. For 60 miles it was run at 109 m.p.h. with Aitken and Resta trying to outmaneuver each other at every turn of the banking. Both had to stop for tires, but both got away again so smartly that it hardly affected their relative positions. From the start to the time when the overstressed crankshaft of Resta's engine gave up the struggle Resta and Aitken had rarely been much more than a length apart.

With Resta's retirement at 65 miles, the race was over. Aitken cut down speed instantly, dropping from 109 to about 103 m.p.h., or even less, a small percentage, but enough to make a big difference in the load on his engine. Thenceforward, Aitken, Wilcox on the third Peugeot and Galvin on a Premier ran in a bunch of three with little variation, the field making some good racing among themselves a lap behind or more.

FINISHERS IN HARKNESS TROPHY RACE—100 MILES

Car	Driver	Time Hr.Min.Sec.	M.P.H.	Prize
Peugeot	Aitken*	56:37.65	105.95	$4,000
Premier	Galvin	56:45.35	105.71	2,500
Peugeot	Wilcox	57:10.53	104.9	1,500
Maxwell	Henderson	59:04.70	101.31	1,000
Duesenberg	Devore	59:05.47	101.3	600
Benedict	Benedict	59:23.88	100.9	400
Hoskins	Hughes	1:01:47. 1	98.2	....

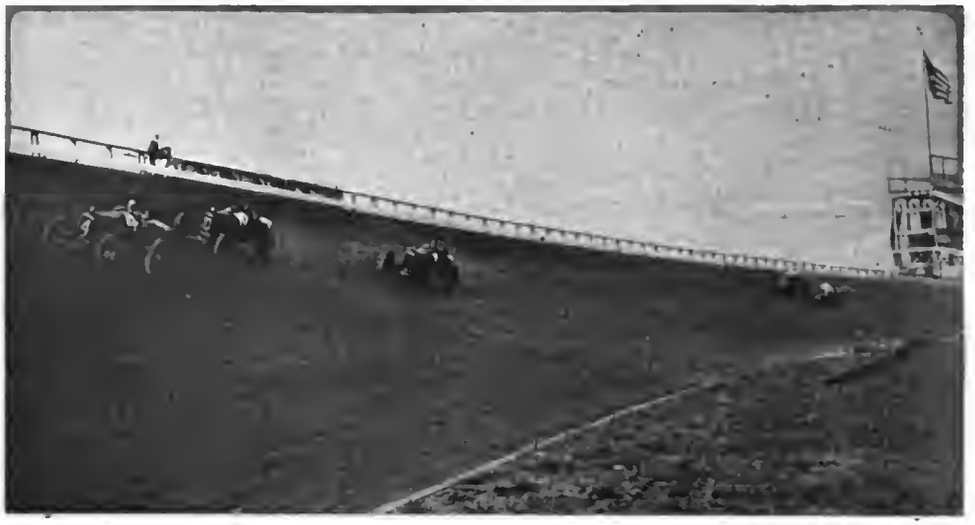
*Lap prizes, $1,400 additional; Peugeot, Resta, $1,400 lap prize.

TIMES OF FINISHERS IN 50-MILE RACE

Car	Driver	Time Hr.Min.Sec.	M.P.H.	Prize
Delage	Le Cain	28:49.59	104.2	$1,000
Duesenberg	Milton	30:15.8	99.25	600
Pugh	Meyer	30:16.36	99.1	400
Duesenberg	Devlin	30:17.11	99	300
Hoskins	Hughes	30:31.40	98.25	200
Crawford	Muller	30:32.4	98.15	....
Crawford	Klein	31:09.65	96.5	....

Possibly had there not been prizes of $50 or $100 for the leader of each lap Resta might not have set so hot a pace. He carried off the lion's share of this lap money up to the point where he went out; in short he had a two-to-one advantage over Aitken, but perhaps Aitken was as much responsible as Resta, for, drive as he would, Resta could never get a car length ahead of his rival.

Nature could offer nothing finer as a setting for so historic a conflict; the sky was the finest autumn blue, there was scarcely a breath of wind and not a cloudlet, yet the sprinkling of people through the high double-decked grandstand was pathetic. Conservatively, not 5000 saw the race from the stand. In the bleachers was a smaller number. The infield had less than 150 parked cars. It was no attendance for so great a conflict. Enthusiasm was lacking, and those outbursts of cheers that Aitken and Resta merited were lacking. When Aitken finished there was but a faint ripple, and it was not until he pulled up beside the pit after having traveled an extra lap or so for safety that the stand seemed to waken to the occasion and greeted the victor with a respectable cheer. A performance which came so near bringing a world's record to this speedway deserved more exultation. Unfortunately the stands were not well enough advised during the progress of the race, and many who might otherwise have been at fever heat were pardonably lukewarm.



Resta's Peugeot leading Aitken and Wilcox coming out of the homestretch. The cars were as close together as this on lap after lap of the 100-mile race

LEADERS AT 10-MILE INTERVALS IN THE HARKNESS TROPHY RACE

Miles	Driver	Time Hr.Min.Sec.	M.P.H.	Prize
10	Aitken	5:39.0	106.2	$100
20	Aitken	11:05.0	108.2	100
30	Resta	16:28.35	109.3	100
40	Resta	21:52.0	109.6	100
50	Resta	27:22.0	109.5	250
60	Aitken	33:49.0	106.2	100
70	Aitken	39:33.0	104.2	100
80	Aitken	45:16.0	106	100
90	Aitken	50:54.0	106.1	250
100	Aitken	56:37.65	105.95	4,000

The intermediate laps which had prizes of $50 each were divided between Resta and Aitken, so that they took $1,400 each, Aitken making the final prize of $4,000 in addition or a total of $1,400 to Resta and a total of $5,400 to Aitken.

Devigne and his Delage, winner of the 50-mile consolation event

Figures best narrate the consistency of the struggle. For 30 miles the speed was over 109 m.p.h. It started at 106.2 for the first 10 miles, jumped to 108.8 at 20 miles, was 109.3 at 30 miles, rose to 109.6 at 40, varied to 109.5 at 50 and was then pulled down to 106.2 at 60, due to stops for tire changes by both Aitken and Resta. With Resta out, there was not the incentive for Aitken to continue at his previous pace, and we find the average remaining at 106.2 at 70, then dropping to 106 flat at 80, rising to 106.1 at 90 and finishing at 105.95 at the century.

Wilcox in Peugeot No. 1 and Galvin in one of the new Premiers deserve creditable mention. Galvin drove a consistent race and made no stop. Wilcox had scarcely such good fortune with his Peugeot. He had to stop at 46 miles to change a right rear. Up to that time he was always one of the first three. The order of passing the grandstand was Resta, Aitken and Wilcox, or Aitken, Resta and Wilcox. Wilcox was rarely over 100 ft. back of the leaders. His tire change was not so good as either Aitken or Resta, as he consumed 25 precious seconds, and after that he was never alongside of the leaders.

The also-rans divided the glory, four of them finishing within the money, the cash being divided over a field of seven. Maxwell, Duesenberg, Benedict and Hoskins shared the remaining positions in the order noted. With the exception of the Maxwell, the other three used Duesenberg motors, so it might be classed as a Duesenberg day in this part of the field. With the exception of the Hoskins, all averaged over 100 m.p.h. Henderson, in the Maxwell, was less than 1 sec. ahead of Devore in the Duesenberg. Unfortunately this hard-fought duel for 100 miles was lost sight of by the majority of the spectators. It was a race within a race, and staged as a separate attraction would have been a grandstand thriller from start to finish.

The tale of the unfortunates, those that started but stopped before the allotted time, embraces the names of favorites and others. Rickenbacher's Maxwell went out with a broken piston before the race was half over. He traveled up with the first group pursuing the Aitken-Resta duet. Vail's Super-six Hudson went out at 20 miles with a burned connecting-rod bearing. LeCain's Delage was out at 40 miles with valve trouble. Lewis' Premier stopped with carbureter troubles at 50 miles and did not continue. Of the other twenty-one starters the majority were running when the seven that carried off the money finished and were then flagged off the course. Of the two Crawfords, one stopped with carbureter trouble and the other was running at the finish.

To-day's race did not afford sufficient data to secure a correct estimate on how cord tires endure at a pace of 109

Start of the 50-mile consolation race for non-winners at Sheepshead Bay speedway

m.p.h. or higher. Only two definite cases are at hand, that of Aitken's right rear at 56 miles and Resta's right rear at 64 miles. It would scarcely be correct to draw deduction from these two examples. In the 250-mile Astor Cup race on this speedway a month ago Aitken did not change a tire in that distance, but he rarely traveled at an average of over 105 miles. To-day for 30 miles he averaged over 109 m.p.h., and this added 4 miles appeared to have a serious influence on tires.

One factor entered into to-day's race that was wanting 4 weeks ago, namely, that both Aitken and Resta did immeasurably more jockeying for favorable positions, and so imposed a proportionately greater strain on the tires. They rode high on the banks to gain impetus on the stretches, a practice which imposed an added strain on the cord pneumatics.

The winner's equipment included Goodyear cord tires, Miller carbureter, Rudge-Whitworth wheels, Hartford shock absorbers, K. L. G. spark plugs, Bosch magneto, and he used Oilzum.

After the 100-mile curtain was rung down there was a consolation race of 50 miles for those not finishing in the money in the big show. Eleven cars started in this race, which proved an easy victory for LeCain in the Delage, which averaged 104.2 m.p.h. for the distance. No records were broken, and it was a procession from start to finish. The race divided itself into three groups, LeCain in the first group, making a runaway of it. He lapped a goodly portion of the field at 26 miles and had the entire field a lap back of him at 44 miles. He did not have to stop, and generally was alone on the track excepting when lapping the two groups into which the field divided itself shortly after the race had really got well under way.

The first group was made up of a Crawford, driven by Klein, Milton's Duesenberg, Meyer's Pugh and Devlin's Duesenberg running a lap back.

The second bunch included Hughes' Hoskins, Vail's Hudson, which started on five cylinders and had eventually to retire, and Muller's Crawford. Both of these groups were very much slower than the winning Delage, or nearly a lap behind the record group.

Protection of cars, track and grandstand against fire was again provided by the H. W. Johns-Manville Co., which distributed a squad of twenty-five men equipped with extinguishers around the track.

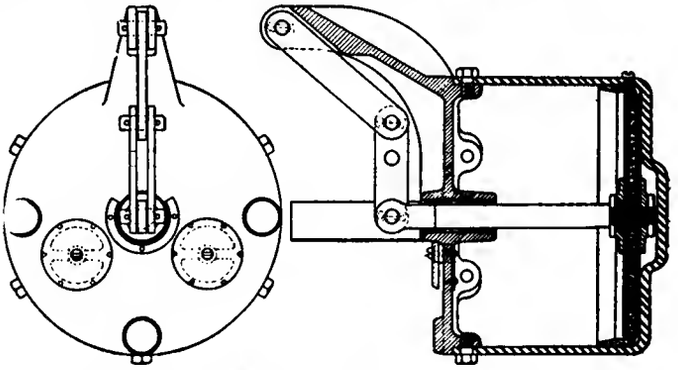
Vacuum Brake for Automobiles

System Used for Train Brakes Applied in Simple Manner to Any Car—Great Delicacy of Control

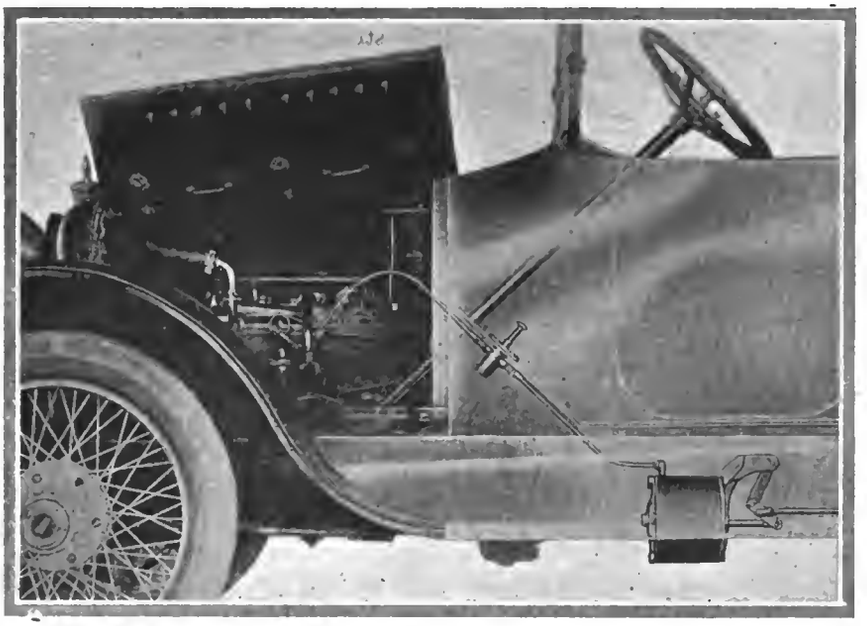
THE idea of using some form of vacuum or air brake for automobiles is not new, but the Prest-O-Lite Co., Indianapolis, Ind., has just worked out an extremely neat and simple form, this being an invention of Benjamin G. Kramer, who also was responsible for the Pierce engine governor.

The system of the brake is to utilize the suction prevailing in the intake manifolds. The few pounds per square inch difference between manifold pressure and atmospheric pressure is converted into a respectable force by the use of a large piston. It is stated that a force of about 10 lb. per square inch is available as a rule, and this is used on a piston of 7 in. diameter with an available stroke of 4 in. A system of levers reduces the travel and multiplies the force correspondingly, so that a powerful pull on the brake operating rod is obtained.

A simple little valve is placed in the pipe line connecting the intake manifold with the brake piston, and this valve can be operated either by foot or by hand, the way in which this valve permits the brakes to be applied with different degrees of intensity being extremely ingenious. To give different amounts of pull on the brake rod it is necessary to have variable depression in the brake cylinder, and we can only get



Section through the vacuum cylinder of the Prest-O-Lite brake



Shows how the Prest-O-Lite brake control is fitted to a car

this by opening the connection to the manifold, allowing a little air to be sucked out and then closing the valve again quickly, otherwise the full suction will come on at once.

This would be a delicate hand operation, so it is made automatic by the valve. The valve is opened by pressing down on a spring which in turn presses on the valve. The lower side of the valve is exposed to atmospheric pressure continuously and the upper side of the valve is exposed to the pressure existing within the brake cylinder. Thus, when the valve operating lever is moved, it presses on the spring and opens the valve. Instantly the pressure back of the valve drops, and the atmospheric pressure on the other side of the valve forces it up against the spring, so cutting off the suction. In this way the depression in the brake cylinder is made proportional to the amount of movement given to the valve operating lever or pedal. Directly the operating lever is released the valve is lifted right back and this admits atmospheric pressure to the cylinder, thus releasing the brake instantly.

The cylinder is very similar to the air-brake cylinders used in braking railroad trains. With a pressed steel shell and a cast steel head, the entire cylinder weighs in the neighborhood of 12 lb. The thin steel piston embodies a leather plunger, a duplicate in design of the type used in locomotive air-brake cylinders, which have been known to give 7 years' service before replacement was necessary.

A representative of THE AUTOMOBILE drove a Packard twin six and a Velie, the former equipped with a hand operated brake and the latter with a pedal. In ordinary driving, through traffic and over hilly country roads the flexibility of the brake could not be questioned. The Packard was put up to 35 m.p.h., the brake lever applied—with a touch of the little finger—and the rear wheels locked, both of them, so that the car slid in a straight path up the road. With one of the brakes thrown out of adjustment, it was again found possible to lock both wheels evenly, as the extreme pressure possible took up the difference through the equalizers. Then again, driving at any speed, it was possible by a shorter movement of the lever to give the brakes the very slightest touch so that their effect was hardly noticeable. Any degree of pressure between these two was easily obtainable.

The brake will operate with enough force to slip the wheels as long as the engine is turning over. As an example of this the Packard was driven by the starting motor alone, meaning that the car was traveling possibly ½ m.p.h., yet full application of the brake lever locked the wheels. It might be noted here that the brakes on the Packard were so set that in order to slip the wheels, it was necessary to throw the entire weight on the regular brake pedal which was connected to the same levers. In descending steep declines where it is possibly advisable to turn off the ignition and leave the clutch engaged, the brake will operate as efficiently as it will with the engine under power.

In the pedal operation as applied to the Velie, driving through crowded traffic was a revelation. The pedal was located directly beside the accelerator. Through the most crowded traffic operation of the car was simply a matter of oscillating the foot from the accelerator to the brake pedal and vice versa, about the same amount of foot pressure being required to operate both. The car was driven into a steep ditch, the brake applied with the foot, a shift made into reverse, the foot switched from the brake pedal to the accelerator and the car slid out without difficulty.

The release is almost instantaneous, so rapid in fact that it is impossible to shift the foot from the brake pedal to the accelerator quick enough to catch the brakes unreleased.

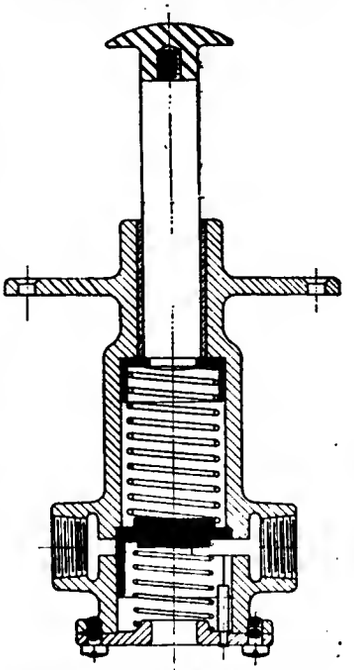
Tight connections are unnecessary. As a matter of demonstration, a system was connected up with each union turned in place with the fingers only. To aggravate conditions a pipe was inserted between the valve and the manifold, which was drilled through. Still the device worked perfectly.

To Fit All Cars

The vacuum brake will be marketed with a view of furnishing brackets for attachment for all well-known makes of cars, both as a factory equipment and retailing proposition. Although it was primarily designed for passenger car use, particular emphasis is laid on its merits as a part of truck equipment, especially in very heavy trucks where it is difficult to create sufficient leverage with a foot-operated brake acting on the rear wheels.

This invention appears to be one that may easily rank in importance with the vacuum fuel feed system. The name of the Prest-O-Lite company is sufficient to guarantee that the device has been tried out with requisite thoroughness and found free from faults and its cost, though obviously greater than that of a plain pedal or brake lever ought not to be prohibitive where quantities are required. Practically the only wearing portions of the whole outfit are the cup leathers, and we know from experience of other machinery that these will last an immense time when protected and lubricated.

It would be difficult to imagine anything much easier to fit, in fact the attachment would be as simple a job as any part of the assembly and the added weight is so small that it may be neglected.



Section of balanced automatic control valve

Australian Imports Increase 200 Per Cent

U. S. A. Supplies Over Two-Thirds of $5,381,275 Worth of Automobile Chassis and Bodies Absorbed by Commonwealth in First 6 Months of 1916—Rubber Shipments $2,643,455

SYDNEY, AUSTRALIA, Sept. 12—Shipments of automobile chassis, bodies and rubber to Australia during the first half of 1916 show an increase of 200 per cent over those of the same period in 1915. That this country is fast coming to the fore as an automobile buying power is manifested in the latest import figures, which show a total of $5,381,275 in bodies and chassis, as compared with $2,543,595 in the first half of 1915. Rubber shipments totaled $2,643,455.

The American automobile makers have taken advantage of the excellent business conditions there and have built up a large trade with each of the Australian States. Over two-thirds of the cars shipped to Australia were from the United States, this country also leading in each of the States. New South Wales, which is the largest automobile buying state in Australia, bought nearly one-half of the cars sent from the United States to that country and increased its imports from that country nearly six-fold over those in the first half of 1915.

$4,297,360 in Chassis

Chassis shipments to the Commonwealth during the first half of 1916 amounted to $4,297,360 as compared with $2,093,740 in the same period in 1915. Of this amount, $2,781,565 was from the United States against $864,840 in the first half of 1915. With the exception of the United Kingdom and Germany, the rest of the countries showed large gains during that period. British imports dropped nearly 60 per cent, or from $587,505 to $312,300; German imports dropped from $17,460 to $1,705. Canada, France and Italy, however, marked up large gains, especially Canada, which shipped cars worth $820,130 as against $356,380. France shipped cars worth $114,675 as against $99,460. and Italy nearly doubled her shipments to that country, totaling $249,740, as against $141,880.

Body shipments were more than doubled despite the fact that this country is a very important one in the matter of body building. Body shipments totaled $1,083,915, as against $449,855 in the first half of 1915. The United States also led in these shipments, sending over bodies valued at $866,490, as compared with $236,235 in the 1915 period. Canada, France and Italy also showed substantial gains over their shipments during 1915. Canadian shipments totaled $163,430, compared with $80,310; French shipments totaled $10,580, as against $2,550; and Italian shipments totaled $10,925 as against $7,910. The United Kingdom, which did a large business of $120,240 worth in the first half of 1915, fell off considerably in 1916, her total being $31,680.

N. S. W. Absorbs Most

In both the chassis and bodies, New South Wales was the leader with $1,757,640 and $454,230, respectively. Victoria was a close second in chassis and bodies with a total of $1,169,585 and $271,955, respectively.

New South Wales is a fertile field for automobile sales. The State is prominent as a farming and pasturage district, and as a result automobiles are in demand especially by the farming element. Not only in this State, but in the whole of Australia is there prosperity. The war has benefited the Australians instead of hampering them. From the very beginning of the war the Australian Government was busy bettering trade conditions. Exports were increased by the purchase of cargo steamers, offsetting the excessive freight rates and the general difficulties in obtaining merchandise.

There is a large demand for commercial vehicles in the farming districts. The farmers are in the field for conveyances that will speed their products to the markets.

Gasoline from Natural Gas

75,000,000 Gal. of Casing Head Gasoline Produced in 1915—100,000,000 Gal. Is Estimate for 1917—Costs 8 Cents Per Gal.—Old Oil Wells Valuable

By Bernard N. Glick

EDITOR'S NOTE:—According to government reports the casing-head gasoline industry, or production of raw gasoline from natural gas, increased 53 per cent in 1915 over 1914, an average price of 7.9 cents per gal. being received for the unblended product. The same authority estimated that 24,000,000,000 cu. ft. of natural gas was utilized, with an average recovery of 2.57 gal. of gasoline per 1000 cu. ft. Mr. Glick has made an exhaustive study of this growing industry with a view to its possibilities as a relief to the situation caused by the ever-increasing demand for gasoline as a fuel for automobiles and motor trucks.

IN these days when rumors of scarcity of crude oil and higher prices of gasoline are general, it is overlooked by many that a new industry in the manufacture of gasoline has been developing during the last 10 years. This is the manufacture of gasoline from natural gas, the natural gas being produced along with oil from the wells from which crude is obtained.

During the year 1915, a total of 75,000,000 gal. of "casing head" gasoline, as this gasoline is named, was produced and the estimated production for this year is over 100,000,000 gal. Since this casing head gasoline is blended with about an equal volume of petroleum distillate before it is marketed as an automobile fuel, the total production of gasoline from this source will be round 200,000,000 gal.

The total production of gasoline from various sources last year was about 1,000,000,000 gal., so that this process in its relatively undeveloped state, already represents a 20 per cent factor of the total supply.

In the production of gasoline from natural gas, from 400 to 500 cu. ft. of gas are needed to produce a gallon of gasoline. At present rates the gas for manufacturing purposes sells for about 10 cents per 1000 cu. ft. With operating expenses in the neighborhood of 2.5 cents per gallon, it costs approximately 7.5 to 8 cents to produce a gallon of gasoline from natural gas. Losses by evaporation, storage and transportation charges have to be added to this but there is evidently left a wide margin of profit with gasoline at present figures.

All Gas Not Available

All grades of natural gas are not suitable for the manufacture of gasoline, in fact, only a small percentage is satisfactory. The variety used is known as "wet gas" and issues from wells along with oil. In some cases where the natural oil flow has stopped the gas is pumped out under reduced pressure, and a number of oil wells which have not been producing oil for several years have been pumped during the past year for natural gas which is eminently suited for this purpose.

Naphtha Treatment Required

The gasoline so manufactured is not used in automobiles directly as produced. It is far too volatile and before it can be so used it has to be blended with refinery naphtha of approximately equal volume. Once blended the fuel is handled just the same as refinery gasoline and is equally satisfactory in use.

The manufacture of gasoline from natural gas was started in 1904, since which time its expansion has been rapid. This industry first reached its highest development in the Appalachian fields extending through Pennsylvania, New York, Southern Ohio, West Virginia and Kentucky, but has since spread to the Middle West and Western States, and just as in the production of gasoline from crude the west has taken the lead, so has it taken the lead in the production of gasoline from natural gas.

In the manufacture of "casing head" gasoline two processes are now used, a third and very promising one being in process of development.

The first, known as the compression and condensation process, and accounting for the major part of the production, is described below.

Refrigeration Used By Few

The second, confined to a few plants, is known as the refrigeration process, cold alone being used to condense the gasoline vapors in the natural gas. The cooling agent used is ammonia, and the process is somewhat similar to the manufacture of ice from water, the heat necessary to volatilize the liquid ammonia first formed by compression being taken from the natural gas, which is thereby cooled sufficiently to deposit the gasoline vapors as a liquid.

The third process, known as the absorption process, is comparatively new, and consists in bringing natural gas into contact with some heavy oil (usually a petroleum distillate) letting this absorb the gasoline from the natural gas and then separating the gasoline from it by distillation. By this method it is possible to treat natural gas that is unsuitable for compression owing to the small percentage of gasoline vapors contained, and it promises to rival in volume of production the older compression process, when developed.

The compression process is the one by which the majority of the gasoline coming from natural gas is produced. The natural gas is compressed in a series of cylinders and after being compressed is passed through a coil of cooling pipes where it condenses and is collected in the form of gasoline. In this process there are several stages of condensation and compression. The first pump compresses to a pressure of 50 lb. after which the compressed gases are chilled in a series of pipes; the second pump compresses to a pressure of 250 lb., receiving its supply of gas from the series of pipes following the first pump. From the second pump the gases are passed into a cooling coil and liquid condensing is collected and any gas remaining passed on to another pump. An equipment for forming gasoline by this compression process will produce 300 gal. of gasoline per day and cost from $11,000 to $12,000.

The apparatus necessary for compression is neither very

extensive nor involved. Quite a number of the compression plants obtain their gas from wells quite some distance away, whence it is brought in pipe lines under reduced pressure. Some of the finest gas for compression purposes is got from wells not delivering oil, under pressures sometimes as low as 2 or 3 lb. The compression operation proper is usually performed in two stages the gas being first of all subjected to pressures varying from 20 to 50 lb. per sq. in.

While the gas is still at this pressure it is cooled by passing through 2-in. iron pipes about 100 ft. long for every 100 cu. ft. of gas passed per minute, anything condensing being retained for mixing with the final product. Usually only a little liquid is obtained at this stage, but in some cases where the gas is very rich in gasoline vapors, as much as 5 or even 10 per cent of the total yield is got here; although this latter figure is rather exceptional.

After the gas has left the cooling pipes it is led into the high-pressure cylinder and is there subjected to pressures varying from 200 to 350 lb. per square inch. The temperature during this operation rises to somewhere around 250 deg. C. (482 deg. Fahr.) and, of course, no liquefaction takes place in the cylinder as this is way above the condensation point of any of the gases involved. The compressed gas is then cooled as before by passing through pipes cooled by water.

In some plants advantage is taken of the fact that when a gas is allowed to expand suddenly from high to low pressure the gas is thereby cooled considerably and this cooled gas is then circulated round the issuing gas to cool it before it also is allowed to expand, thus getting a cumulative cooling effect similar to that employed in the liquefaction of air. The most suitable pressure to use in the high-compression cylinder is usually determined by actual practice. The yield increases with increased pressure, but there is a very definite point beyond which it is inadvisable to go. If this is ignored the resulting product is known in the trade as "wild" and sometimes as high as 60 or 70 per cent of it vanishes on exposure to atmospheric conditions. Even when the pressures used in the second stage of the operation are not too high the liquid produced is still rather unstable for varying weather, storage and transportation conditions and at present practically all this condensation product is blended with refinery naphthas to obtain a more stable product still capable of use as gasoline.

These blending agents are the lower distillation products of petroleum:

Rhigolene, boiling point	18 deg. Cent.
Petroleum ether, boiling point	70-90 deg. Cent.
Naphtha, boiling point	90-120 deg. Cent.

While these petroleum distillates are not volatile enough for use in gasoline engines, by blending with the almost too volatile natural gas condensate, a stable gasoline substance

Third row—Lieut. Col. George O. Squier, charge aviation section, U. S. Army, Director S. W. Stratton, Bureau of Standards, H. J. Stagg, Jr., guest, G. Douglas Wardrop, Chairman A. Ludlow Clayden, H. L. Horning, Clarence Carson, Andrew L. Riker

Bottom row—Russell Hoopes, Charles M. Manly, W. J. Hart, Raddford Pitt, Councilor David Beecroft, L. C. Fuller

is obtained, capable of being stored and shipped in barrels and tank cars without serious loss.

In this process only about 15 per cent of the gas is removed, although in some places where exceptionally rich gas is used as high as 50 per cent or more disappears during compression, and the residual gas is still a very valuable product. Its thermal efficiency compared with the original gas is almost unimpaired, while for lighting and power purposes it is in many cases improved. With wet gases trouble is often caused in gas engines by premature ignition due to the contained gasoline vapors, and similarly, when burned in standard burners, sooty flames are produced, owing to their incomplete combustion. The wet gas really has merely been changed during the operation into a comparatively dry one, comparative only, for in plant practice all the gasoline constituents are never removed. This residual gas therefore is often turned into the ordinary gas mains or used on the least for running the engines and pumps, while some plants compress it in steel cylinders and sell the product for various purposes under the name of "gasol."

125,000 Cu. Ft. Per Day

The usual sized plant handles round 125,000 cu. ft. of gas per day which, averaging round 2.5 gal. of gas per 1000 cu. ft., will produce about 300 gal. of gasoline daily; smaller plants not having been particularly successful.

The equipment for plants handling up to about 500,000 cu. ft. of gas daily and producing about 1200 gal. of condensate will cost in the neighborhood of $8,000 to $10,000 under normal conditions, pipe lines to wells, railroad sidings, storage tanks, etc., being extra, and can be operated night and day without any undue exertion by two or three men, a plant handling up to 1,000,000 cu. ft. being easily cared for by six.

A case quoted in a government bulletin gives details of two plants costing $40,000 for complete equipment. Operating expenses, including salaries and repairs, for the year 1913 were $11,000. The two plants sold 490,000 gal. of gasoline, for most of which they received 13½ cents per gallon. Taking 11¼ cents as an average, the gross income was $55,125, the net income $44,125 or round 110 per cent on the original investment. Some idea of the value natural gas has attained may be derived from the fact that in the States of West Virginia and Pennsylvania, two of the greatest oil producers, the value of the natural gas produced in 1914 surpassed by a comfortable margin that of the crude oil.

Natural gas has long been known as one of the most efficient of fuels. It is clean, easily handled, has high calorific power and efficiency of combustion and competes very successfully with coal as a source of power. Its slight toxic effect combined with these properties renders it also particularly suitable for domestic lighting and heating, no new

Casing Head Gasoline Production Statistics for Ten States

Colorado	Not available						2		
Kentucky	1,421,818	34.52	490,875				0		
	591,866,733	19.16	88,413,764	16,894,557	889,906	2.43	386	179,353	42,652,632

fact, for it is said the ancient records of China and Japan contain many allusions to its use for these purposes. Its value as such, however, has always been restricted by an area that could be conveniently covered by pipe line transportation from central compression stations, and this has certainly helped to keep its properties and uses of merely local importance.

Occurs in Oil Fields

The gas occurs in most of the States where oil is found, sometimes along with the oil, but often entirely separate from it. Where the two occur together it is still unfortunately the custom to waste the gas, especially in large scale operations, owing to the desire to produce and market the more easily accessible oil as soon as possible. When the well is first opened the quantity of gas that is allowed to escape is enormous, often reaching 10,000,000 to 15,000,000 cu. ft., a custom doubtless responsible for the premature ending of what might be otherwise productive gas fields. It is an eminently uneconomical method of exploitation in the long run, for while the reduction of pressure caused by this blow off of gas may cause a greater initial flow of oil from the surrounding strata into the well, there is little doubt that the lessening of the expulsive force that follows results in a shorter productive life. Were the gas retained in the oil-bearing strata the pressure it exerts would keep the well producing naturally much longer and also stave off the inflowing of water or brine usually occurring along with the oil.

Some idea of the extent to which this industry has attained can be got from the following figures gleaned from various government reports. The value of the natural gas consumed in the States, excluding the millions of cubic feet that simply come to the surface and escape having served no useful purpose, has increased 500 per cent in the last 15 years.

Year	Value	Year	Value
1899	$20,000,000	1913	$88,000,000
1905	40,000,000	1914	94,000,000
1912	84,000,000	1915	100,000,000

This rise has been due in a large measure to increased production, helped along by increasing prices since 1906. Of this gas only a small percentage is available for use in the production of gasoline, most of it being "dry." In 1914 with a total consumption of 592,000,000,000 cu. ft. only 17,000,000,000 cu. ft., or about 3 per cent, was utilized in the production of gasoline. The prices obtained for this gas varied according to its use, about 34 per cent or 203,000,000,000 cu. ft. being utilized for domestic purposes at an average cost of 28.04 cents per 1000 cu. ft. and the remainder for industrial purposes round 9.56 cents. The number of condensation plants, their capacity and production, has gone up in leaps and bounds as is eloquently shown by the following table:

Year	Plants	Daily Capacity, Gallons	Gasoline Production, Gallons
1911	176	37,100	7,500,000
1912	250	61,268	12,000,000
1913	351	152,415	24,000,000
1914	386	179,353	42,500,000

The price obtained for this gasoline was in the neighborhood of 10 cents per gallon, those doing their own blending realizing up to 12 and 15 cents. By States the complete statistics relating to the condensation and compression for the year 1914, the latest available, are summarized above.

(*To Be Continued*)

1916 Output To Be 98,000 Trucks

(*Continued from page* 745)

and accessories were among the most difficult articles to obtain, and some companies were seriously upset by the fluctuating and irregular quantities available. Another difficulty was in obtaining trailers, which were in much greater demand during the past year than ever before, and still another factor which made things harder for the truck makers was the freight car shortage and its attendant worries as to delivery.

180,000 Trucks in Use

As for the number of trucks in use, although no accurate statistics are available for all the States, it is significant that on July 1 there were 71,000 motor trucks in use in only seventeen States, not including such important centers as Illinois, Michigan, Minnesota, California, Connecticut, etc. This makes a striking comparison with the total of 23,855 registered in all the States at the end of 1911. A conservative estimate would place the total number of motor trucks in use in the entire country at the present time at close to 180,000, this figure not including the various types of converted passenger cars and similar makeshifts.

Domestic Demand Much Larger

Altogether, the developments of the past year indicate that the motor truck industry has made another enormous stride forward and that although the war orders have been large and remunerative, the domestic demand has grown in a way that completely overshadows export business.

Three years ago the truck industry needed a period of general good business, a period when the business men of America had money in their pockets and were willing to try something new. That period came with the beginning of 1915 and the industry leaped forward to take advantage of its opportunity.

Steam Cars, Past and Present

Modern Vehicle Vastly Better than Old Types—Causes of Trouble Eliminated from Modern Steam Cars*

By Abner Doble

THE Stanley steam car has been consistently manufactured since 1898 without cessation. The Stanley Bros. have maintained a production of about 600 cars a year, without paid advertising of any description, although they have very recently started a campaign. Their sales force has always been very meager, largely because people interested in steam cars simply went and bought them.

The evolution of their car has been gradual and conservative and Stanley cars have enjoyed a well merited reputation for service at low cost. They have used a fire-tube boiler and locomotive-type engine from the very first, and were not led astray by such faddish brain storms as single acting engines and red hot steam, which served to kill off such a large percentage of early builders. Improvements were added only when there was a well recognized demand from their customers. They have thus accumulated those necessities of modern motor cars, such as dynamo, electric lights, streamline bodies and one-man top, including a condenser, which they adapted to their car in 1914, and which allows about 200 miles' run on one filling. They now burn kerosene in the main burner (with gasoline for starting and for the pilot), and secure a very large mileage per gallon.

The fusible plug and its terrors were abandoned in favor of a thermostat for shutting off the fuel in case the driver ran short of water. Altogether the Stanley car has proved a very remarkable exception to regular automobile production.

Increased Water Mileage

One great disadvantage that steam cars labored under was insufficient mileage on the amount of water which could be conveniently carried. This was accompanied by the emission of good sized clouds of steam, and necessitated considerable searching at inopportune times for a further supply. Several steam cars were equipped with an apparatus intended to condense the steam, but a continuous run of a hundred miles without refilling was exceptional. Due to the use of heavy cylinder oil, these condensers as well as the water tank required periodical cleaning, which was an exceedingly distasteful job. Steam cars not so equipped would run approximately 30 to 35 miles on a tankful, about 35 to 40 gal. In order to handle such large quantities of water, a steam syphon was used to fill the tank.

On making our preliminary investigations we found that no one apparently had considered using a honeycomb radiator, which would, in the same size, give approximately six times as much radiating surface. The reasons advanced against this use were that the thick oil was liable to clog the extremely small passages, and that the exhaust steam (particularly in cars with flash boilers) was liable to melt the solder. We also found a superstition to the effect that oil would injure the boiler and cause violent foaming. It was also believed that the successful lubrication of a steam engine required a heavy oil with a molasses-like behavior. It was particularly hard to reconcile these beliefs, and we determined that the best thing to do was to put a honeycomb radiator onto a car and operate it in conjunction with a fire-tube boiler. This we succeeded in doing late in 1913, and realized several startling results. The car would run anywhere from 1000 to 1500 miles on one supply of 24 gal. of water. The boiler in its operation was entirely oblivious to the fact that all of the oil used by the engine cylinder was pumped into it. Having established with absolute certainty that it was possible to travel an adequate distance on one supply of water, we turned to the study of the steam-generator, with special regard to its operation when fed with water containing oil, graphite, and in winter, alcohol.

Defects of Flash Boiler

The so-called flash boiler, comprised of a series of coils forming, in effect, one continuous tube, was naturally out of it, as its entire absence of steaming stability was a source of constant aggravation to a driver in a hilly country. However, it had the immense advantage that the direction of the water-flow was opposite to the flow of the gases of combustion, which placed the coolest water in position to take the last possible B.t.u. out of the flue gases. Its all steel construction with the consequent immunity from leaks due to low water was also a great advantage. These were worth having, so we marked them down on our specification of the perfect boiler.

The vertical fire-tube boiler was also out of the question for production, on account of its great weight, potential danger present with a large diameter shell, the high cost due to the apparent necessity for winding the shell with a mile of piano wire, liability to leaks from oil working through the expanded joints where the tubes are fastened into the heads, and to overheating with low water. Notwithstanding these formidable disadvantages, it was the nicest boiler from the driver's standpoint when in good condition, due to its large reserve of water heated to the steam temperature, which admitted of a perfectly terrifying acceleration, and gave a feeling of absolutely unlimited power. It was also the most efficient boiler due to the regular close arrangement of the heating surface with extremely short distance through which the gases radiated their heat to the tubes. These advantages were therefore added to our specification.

The water-tube boiler, which has been built in almost every conceivable shape for motor vehicle service, had a black eye, and yet seemed to offer a basis on which the good characteristics of the flash and water level types of boilers might be combined. This at first seemed a very forlorn hope, as the maze of apparently conflicting conditions seemed unreconcilable.

Deposits of scale occurred in every type of boiler, with a resultant drop in efficiency and added liability of burning the already highly stressed heating surface.

In the water-level types of boilers, this scale would settle particularly in non-circulating portions of the boiler, such as the water column, and blow-off connections. This condition was the cause of most of the little bothers which beset the steam-car user.

In studying the apparently conflicting phases of this situation, we could see that every function was closely re-

*Paper read before Cleveland Section S. A. E.

lated to all others. That is, a water-level type of boiler held the temperature of the medium practically constant, with no possibility of temperatures high enough to effect a deleterious change in the lubricating oil. This allowed the continuous re-use of the oil. It also allowed the use of a soldered radiator to condense the exhaust steam. The honeycomb radiator condenses such a large portion of the exhaust steam, that very little make-up water is required, with the result that much less scale is introduced into the system. Since very little medium is lost, especially in winter, alcohol can readily be used in large enough proportions to keep the car from freezing up. The use of a mixture of alcohol and water results in an imperceptible drop in power due to the large amount of heat carrying medium that must be circulated. By using regular gasoline engine cylinder oil for the lubrication of those parts in contact with the steam, we were able to make a steam generating and condensing system of this kind practical. First, it is more agreeable to handle and easier to procure than heavy steam oil. After it is introduced into the circulating medium, it rapidly goes into an emulsion with the water, due to the violent agitation and intimate contact. It cannot form clots and clog up the radiator passages, and since the return from the radiator is introduced into the bottom of the water-tank, the agitation of the contents of the tank is sufficient to maintain the emulsion. This insures that the oil is regularly pumped into the boiler along with the water. The oil that thus finds its way into the boiler performs several valuable functions. First, it thoroughly coats every portion of the interior of the boiler with an exceedingly thin coating of oil. While this coating is extremely thin at ordinary temperatures, it is very much thinner at 485 degrees Fahr., which is the approximate temperature of the boiler at 600 lb. pressure.

Scale Cannot Stick

No scale will stick to a surface coated with oil, so that the interior of the boiler is absolutely protected from accumulations of scale as well as from rusting. Although there is very little scale bearing water introduced into the system due to the efficient condenser, in several years' operation, there would be an accumulation of the scale formed large enough to render a boiler useless, even though no scale adhered to the tubes. The second function of the oil in the water is to combat this condition, which it does with thoroughness and dispatch. As soon as a particle of scale material is thrown out of solution it is thoroughly coated with oil, which renders it incapable of sticking to any other particle of scale material. This scale, therefore, remains in suspension, and due to the violent ebullition and constant flow of the medium toward the steam outlet, is carried along and out with the steam, finally ending up in the water-tank. This action appears to be exceedingly thorough, and in several years' use no accumulation of scale can be detected in any portion of the boiler.

The steam generator, which has been worked out to fulfill these inter-related conditions, is a flash-generator in theory, and yet has the appearance of a water-tube boiler and carries a water-level in the evaporating zone. The close regular heating surfaces duplicate the heat transference conditions of a fire-tube boiler, and yet the progressive water flow, counter to the flow of the gases, with no circulatory flow, is true of the flash type. The water enters the bottom of the economizer-zone, and flows to the top under the action of the pumps, and gravity, which means that the hottest water collects at the top. From here the water overflows through a connecting pipe into the evaporating-zone, where it is converted into steam. The water level is maintained about half way up the generator by means of an automatic by-pass valve, so arranged that when the regulator tube is filled with steam and consequently hot, the by-pass valve is closed by the expansion of this tube, forcing the water from the pumps to lift the check valve and enter the generator. As the water level rises, the regulator tube is filled with water from an exposed pipe leading from the water manifold. This water is not in circulation in the generator, and, therefore, remains quite cool. The regulator tube contracts, opening the by-pass valve, allowing the water to return to the tank.

Perhaps the greatest disadvantage of steam cars was that known as "firing up," or getting the burner started to raise steam. After a fairly discouraging series of experiments, we discovered that kerosene could be ignited by an electric-spark with absolute certainty and regularity if certain conditions were observed. These conditions were: First, the kerosene must be broken down mechanically so that the individual particles are sufficiently small to insure a rise in temperature past the point of ignition in the time element during which they absorb heat from the spark. Second, the spark must occur near the atomizing nozzle where the fog is dense enough, so that one group of kerosene particles igniting would invariably ignite the rest before being consumed. Third, the velocity must be sufficiently low so that the particles have time enough to absorb sufficient heat from the spark to pass the igniting temperature. Fourth, the mixture must be very much richer at the place where ignition is to occur than the best mixture for efficient combustion.

In connection with the mixing and igniting apparatus, it is necessary that the combustion shall occur in a refractory chamber so arranged that it attains a very high temperature. The intensely hot chamber gives an ideal thermal condition, and complete combustion of a large amount of fuel can be obtained in a very small space.

Thus, in the complete apparatus, we have an electric-motor, direct connected to a multivane blower, and a graduated kerosene pump. The kerosene pump draws a measured quantity of fuel from the supply tank and forces it through the atomizing nozzle; the resultant fog is ignited by a spark plug. A measured amount of air is forced in by the multivane blower, which whirls this rich ignited mixture down through an inlet tube against the bottom of the refractory combustion chamber, where the fuel is consumed. To stop the combustion it is only necessary to break the blower-motor circuit. This is done automatically by means of a regulator set to operate at a pre-determined steam pressure.

Having thus reviewed the situation, and having described what specific mechanism has been designed (and tested) with a view to bringing the steam power plant as near perfection as possible, it might be well to consider what advantages may be rightly expected with a perfected steam power plant, and to compare the operation of the present day gasoline car.

Steam Car Qualities

1. 100 per cent torque range, with maximum torque available at zero speed, thus making superfluous change gear mechanisms and clutch. The M. E. P. (and its equivalent D. B. P.) always under control of the operator, and variable by means of the throttle from zero to maximum, a maximum which is limited only by the tractive capacity of the driving wheels.

2. Utmost mechanical simplicity, with not over 25 moving parts in the entire car, and only 15 in the engine.

3. Perfectly smooth and quiet, due to very low engine speed with one to one ratio, and to location of engine on axle.

4. Low running cost due to use of kerosene or crude oil for fuel.

5. Low manufacturing cost due to simplicity—to lack of fussy work in production.

6. High thermal efficiency, which should be at least twice the efficiency of an internal combustion engine at ordinary driving speeds. As the maximum performance of automobiles is pushed higher, the greater will be the advantage of the steam plant under everyday operation.

7. Entire absence of lubrication troubles, since no contamination of the crank-case oil, by kerosene, gasoline, water, road-dust, and carbon, can take place. The internal lubrication of cylinders, etc., is mostly accomplished by the water in the steam.

Industrial Miscellany

Factory

McIntyre Manufacturing Co., Columbus, Ohio, maker of the Farm Boy Tractor, has received an order for three tractors to be shipped to London, Eng., at once. Other orders from abroad are in prospect. In fact, business is so good that the present plant, located at 172 West Locust Street, is too small and the company is casting about for a location to erect a larger plant.

Xcell Manufacturing Co., located at 321 Mount Vernon Avenue, Columbus, Ohio, manufactures a device for the raising and lowering of Ford tops.

Crow Motor Co.'s plant, Elkhart, Ind., is being enlarged with a two-story addition, 125 by 60 ft. The addition is made necessary by the increased business of the company. The trimming and body departments will be located in the new building.

Elgin Motor Car Co., Chicago, Ill., is planning an addition to cost $75,000.

Perlman Rim Co., Jackson, Mich., is building an addition, 100 by 440 ft., and another, 80 by 380 ft., in addition to a former enlargement earlier in the season.

Simplex Automobile Co., New Brunswick, N. J., is planning the erection of a new plant for the manufacture of automobile bodies. A new factory for the manufacture of aeroplanes is also under consideration.

Goodyear Tire & Rubber Co. factory staff met the managers of the Southeastern District and their salesmen in Atlanta, Ga., recently for a 3 days' convention. All phases of the business of the past year and plans for the future were discussed. During the meeting it was announced that J. E. Taylor, sales-manager of the Atlanta branch, had been promoted to a place in a new department of sales promotion at the factory. Mr. Taylor had been in Atlanta 4 years and Charlotte, N. C., 3 years in Goodyear service.

Columbus Auto Parts Co., Columbus, Ohio, is doing a large business in automobile hardware, which is its specialty. Included in the list are wind-shields, robe brackets, foot rests, hub caps and other accessories. The company has recently booked large orders from automobile factories. C. J. Krag is president and R. E. Klager, secretary-treasurer.

C. A. S. Products Co., Columbus, Ohio, which manufactures gears, has booked an order for $75,000 worth of gears from a Cleveland automobile plant. This order, with others already on the books, will keep the plant busy for the coming year. The concern now employs 130 men. The plant is too small for the development of the business and an effort is being made by Adrian, Mich., to have the plant removed to that city.

Auto Cushion Fender Co., Columbus, Ohio, which was recently reorganized from the Welton Fender Co., is progressing nicely at its new place of business, the Columbus Auto Brass Co. Two sizes of fenders are now being manufactured. Dr. John M. Thomas is president; Dr. Fred Fletcher, secretary-treasurer, and J. W. Howe, general manager.

Personal

C. F. Barth has been appointed works manager for the C. F. Wilson Body Co., Detroit, Mich. Mr. Barth was formerly the factory and production manager for the Murphy Chair Co.

Willis Hollingsworth, South Bend, Ind., who has been connected with the Overland company, sailed Oct. 21 on the St. Paul, for London, where he will become instructor mechanic for the Overland company of Great Britain.

J. H. Guy, his wife, and Master Arthur Guy, of Laporte, Ind., were passengers of the Alaunia, of the Cunard line, which left New York for Falmouth and London, and struck a mine in the English Channel Oct. 19 and sunk. Mr. Guy was formerly vice-president of the Advance-Rumely Co. of Laporte, and resigned recently from the office. They were rescued from the steamer.

P. J. Wood has become sales manager of the Montreal, Que., branch of the McLaughlin Motor Car Co. Mr. Wood succeeds the late C. M. Bennett, and has been for many years with the McLaughlin company, previous to which he was connected with the Pope-Hartford Motor Car Co. of Canada.

Joseph Livingston, formerly assistant branch manager of the Studebaker Corp., at Omaha, Neb., has become manager of the Cleveland branch of the Maxwell company.

T. W. Warner, formerly with the Warner Mfg. Co., is manager of the Chevrolet Motor Co., Toledo.

E. L. Baker, Indianapolis, has been appointed president and general manager of the recently organized New Madison Sales Co., which will distribute Madison Sixes in Indiana. The Madison Motors Co., Anderson, Ind., recently was reincorporated with a capitalization of $2,000,000.

W. J. Hearn, head of the Hearn Tire & Rubber Co., dealer in automobile tires of Columbus, died suddenly of acute indigestion at the age of 52 years.

The Automobile Calendar

ASSOCIATIONS

Nov. 22—Boston, Mass., National Assn. of Automobile and Accessory Jobbers' Meeting.

Dec. 2-9—Electricians' Country-wide Celebration.

Jan. 9—New York City, National Automobile Chamber of Commerce, Annual Banquet at Waldorf-Astoria.

Jan. 9-11—New York City, Society of Automobile Engineers Mid-Winter meeting, Thursday, Jan. 11, S. A. E. day. Annual Banquet, Hotel Biltmore. Special performance Ziegfeld's Midnight Follies.

CONTESTS

Nov. 16 and 18—Santa Monica, Cal., Vanderbilt Cup and Grand Prix Races.

Nov. 18—Phoenix, Ariz., 100-mile free-for-all Track Race. Arizona State Fair.

Nov. 24 and 25—Newark, N. J., 24-Hr. Endurance Run of N. J. Automobile and Motor Club.

Nov. 30—Uniontown, Pa., Speedway Race.

Nov. 30—Los Angeles, Cal., Ascot Speedway 200-mile Championship Race.

1917

April—Los Angeles to Salt Lake City Road Race.

May 19—New York Metropolitan Race on Sheepshead Bay Speedway.

May 30—Indianapolis Speedway Race, Championship.

June 9—Chicago, Ill., Speedway Race, Championship.

June 23—Cincinnati, Ohio, Speedway Race.

March 14-17—Davenport, Ia., Show, Coliseum Bldg., Tri-City Automobile Trade

M. L. Gallagher has been named as manager of the J. Mann Motor Co., Spokane, Wash., Studebaker distributor.

George L. Trotter Co., Seattle agent for the Stearns-Knight, Reo, and Stewart trucks, will soon erect a building near the corner of Bellvue and E. Pine Street, which will be of reinforced-concrete and brick construction, two stories high, and 50 by 107 ft. in dimensions.

B. E. Scearce, assistant manager of the Seattle branch of the Motor Car Co., has been appointed factory representative for the company in charge of the Montana territory. He will be succeeded by William Bradshaw.

A. J. Shorrock has been appointed manager of the Auto Tire & Rubber Co., Seattle.

W. A. Wallace has taken the agency for the Ford car in the E. Pike Street district of Seattle, Wash.

Harry Gowdy, better known as "Hank," the hero of the 1914 world's baseball series when with the Boston Braves, has taken a position as salesman with the Campbell-Gilchrist Sales Co., 15-17 North Fourth Street, agent for the Empire and Pennsylvania tires.

E. M. Dalley, proprietor of the Paige Motor Car Co. at New York, has bought an interest in the agency at Boston and the company there has been reorganized as a result. At first it was believed that the New York Paige agency would absorb the New England one. A new company has been formed now with Sherwood Hall, Jr., who has handled the car at Boston for some years as president, but Mr. Dalley is treasurer. W. B. Hennigan is sales manager. The company will occupy a new building that is to be erected at the corner of Commonwealth Avenue and Beacon Street.

H. F. Reid has become a stockholder and been appointed purchasing agent of the Fen Far Co., Cleveland. He has severed his connection with the M. & M. Co., Cleveland.

A. L. Edwards has been made manager of the Detroit branch of the Kelly-Springfield Tire Co. He is a son of G. D. Edwards, who died recently, and was manager up to the time of his death.

G. F. Weaver, formerly branch manager for the Jeffery in Cleveland, and later sales manager of the Philadelphia agency, has been appointed manager of the J. Harry Schumacker Co., which handles the Dorris and Moon cars in this city.

Dealer

Hainsworth Motor Co. has opened a branch in Tacoma, Wash., where the Oldsmobile will be sold under the management of A. B. De Castellane.

E. M. Lang has taken the agency for the Maxwell, Oakland and Chalmers cars at Auburn, Wash.

Knight Tire & Rubber Co. has closed its Seattle branch, and its products will be handled locally by the Pacific Tire & Rubber Co. in the future.

Mitchell Motor & Service Co., Seattle, have been appointed distributors of the Hal. Twelve in western Washington.

McNatt & Ferguson have taken the agency in the state of Washington for

H. Johnson has purchased the Commercial Auto Co., Tacoma, and has appointed Arthur Contay as chief of the mechanical department.

the Sun Light Six. They will have salesrooms at North Yakima, Seattle and Spokane.

Seven-Seven Co., distributor of Dodge cars in Spokane, Wash., has contracted to handle the Kissel line in Spokane and the Inland Empire.

Siler Auto Co., Spokane, Wash., has taken the agency in the Inland Empire for the Allen.

Maxwell Motor Sales Corp., Philadelphia, has located in its new service station at Twenty-second and Spring Garden Streets, formerly the Park Garage.

Buick Motor Co., Philadelphia, recently moved into its new building and service station at Broad and Poplar Streets.

John G. Wollaeger Co., 417-421 Wells Street, Milwaukee, Studebaker distributor for Wisconsin, has been appointed Milwaukee dealer for the Peerless Eight.

Calumet Garage Co., Calumet, Mich., has been appointed dealer in Jordan and Liberty cars.

F. D. Halferty, Antigo, Wis., is a new Dodge Bros. dealer for Langlade County.

Pathfinder Sales Co., 163 Eleventh Street, Milwaukee, has been appointed state distributor of Empire cars.

Wallace C. Hood, president of the Wallace C. Hood Service Bureau, Detroit, has enlarged his office space in the Dime Bank Building.

St. Louis Battery Co., St. Louis, has opened a sales and service station for Ever-Ready batteries at 3215 Locust Street.

Efficiency Oil Co., St. Louis, announces a service station for Mileometer tape at 3213 Locust Street.

Springfield Body Co. has opened a New York service station at 22 West Sixty-first Street. Chas. Baasch, formerly located at the factory in Springfield, Mass., is manager of the station.

KisselKar will for the first time be represented in Detroit by the George W. Franklin Co., 698-700 Woodward Avenue.

McCurdy-Brainard Co., Philadelphia, has been formed and will handle the Jordan car in Pennsylvania, New Jersey and Delaware. The company is headed by R. P. McCurdy, formerly Pierce-Arrow agent in Pittsburgh.

The Hudson-Stuyvesant Co., Cleveland, plans to erect a $500,000 plant devoted entirely to the sale of Hudson cars in Cleveland.

Gomery-Schwartz Co., Philadelphia distributor of the Hudson, has awarded the contract for the erection of a ten-story concrete building at Broad and Cherry Streets, costing about $400,000. The building will measure 137 by 180 ft.

O'Meara-Green Motor Co., Denver, has opened a Ford agency and service station at 1439 Cleveland Place.

Southwest Motor Co., Kansas City, Mo., has employed C. C. Tanner, formerly with the Halladay Motor Co., St. Joseph, Mo., as district manager for the Reo in Kansas and Missouri. C. B. Haycox, formerly district manager of the Velie Motor Car Co., Oklahoma City, and E. B. Baxter, formerly with the Buick and Studebaker companies of this city, have been added to the force.

Ebbeler Motor Car Co., St. Louis, distributor of Mitchell cars, has added the Metz for Missouri, southern Illinois and northern Kentucky.

Hathaway Motor Co., Kansas City, Mo., has taken on the Monroe and the Oldsmobile.

Buick Motor Co. has discontinued the sale of cars at retail in Milwaukee. The West Side Buick Co. will be Buick distributors under E. M. Jordan, formerly connected with the Buick Motor Co.

Fisk Tire Co., St. Paul, has moved to new quarters at 179 West Sixth Street with service station for forty cars at 402-404 North Exchange Street.

St. Paul Chandler Co. and White Auto Co. have opened new quarters at Sixth and Seventh Streets.

Detroit Electric Car Co., St. Paul, has begun erecting a sales and service station at Grand Avenue and Milton Street.

Elgin Motor Sales Co., Minneapolis, has been incorporated at $20,000 by H. S. Baker and R. G. Rowland of Minneapolis and G. S. Bannon of St. Paul.

Carlson Motor Car Co., Minneapolis, has been incorporated at $50,000. It will handle Kisselkar in the Northwest. W. T. Carlson is president and manager.

Wayne Oil Tank & Pump Supply Co., Davenport, Iowa, has purchased a lot on Seventeenth Street, near Second, in Rock Island, Ill., and will erect an oil service station of brick, one story in height. It has been decided to establish a series of these independent oil stations in the leading cities of the Middle West in order to take care of the automobile trade.

Bosch Magneto Co. has purchased a large plot of ground in Chicago upon which it will build a new and enlarged branch building. The erection of a new building has been rendered necessary largely by the big increase in general business of the Middle Western section. The present location, which is at Michigan Avenue and 24th Street, having an area of 6000 sq. ft., will be vacated about Dec. 1 for the new branch building located on the corner of Michigan Avenue and 37th Place, a location somewhat further south on Michigan Avenue and about midway between the old and new automobile districts. The spare parts, sales and repair departments will be on the main floor, as well as the stock room, the disassembling, washing and testing department, packing department and installation departments. The second floor will house the reception room, manager's office and trade department, as well as the superintendent's office, general office, financial department and drafting room.

Detroit Lubricator Co., Detroit, has issued a new folder descriptive of the latest Stewart carburetor installation for Ford cars.

Stearns Motor Car Co., St. Louis, has been reorganized to handle the Stearns-Knight car. The company will be reincorporated with G. B. Self, Howard L. Austin and A. L. Walsh as chief stockholders. A show room, 40 by 75, with a service room in the rear, has been leased in the Missouri Life Building at 1507 Locust Street.

Lackawanna Automobile Co., Packard, Chalmers and Saxon dealer, has let a contract for the erection of a five-story sales and service building at Vine and Wyoming Streets, Scranton, Pa. The building will have a floor space of 40,000 sq. ft. and will be ready for occupancy in March.

Elcar Motor Sales Co., Indiana distributor for the Elcar, last week closed a lease for two automobile display rooms being erected at 327 North Capitol Avenue, Indianapolis.

VOL. XXXV NEW YORK—THURSDAY, NOVEMBER 9, 1916—CHICAGO NO. 19

New Co. Takes Over Pierce-Arrow

Pierce-Arrow Motor Car Corp. Formed to Acquire Present Company Stock

NEW YORK CITY, Nov. 8.—The Pierce-Arrow Motor Car Co., Buffalo, N. Y., will be taken over by the Pierce-Arrow Motor Car Corp., which has been formed with 100,000 shares of 8 per cent convertible preferred stock and 250,000 shares of common without par value. A syndicate of New York bankers, headed by J. & W. Seligman & Co., will underwrite the new issues.

The new capital will be used to increase the factory facilities.

George K. Birge, now president of the company, and prominent in the wallpaper business, will retire, and Col. Charles Clifton, now treasurer of the concern and for several years head of the N. A. C. C., will succeed him. Otherwise there will be no change in the organization.

Details of the refinancing plan so far determined provide that the preferred stock will be redeemable at 125, and will be convertible for common on a share-for-share basis. It is also provided that for every dollar in dividends paid on the common stock in excess of $5 a share there shall be set aside $1 for the purchase of the preferred stock. This preferred stock, when acquired, will be exchanged for common, and will be considered available for any stock dividends which may be declared. All of the stock of the existing company will be acquired and arrangements are being made to retire the $1,250,000 of 6 per cent bonds on Feb. 1.

Firestone Capital to Be $15,000,000

AKRON, OHIO, Nov. 3—An increase from $4,000,000 to $15,000,000 in the capital of the Firestone Tire & Rubber Co., this city, was authorized yesterday by the stockholders. Two-thirds of this will be preferred and one-third common. Of the preferred, $5,000,000 is to be outstanding for the present. The nominal value of the common stock will be reduced from $100 a share to $10 a share and present shareholders will receive ten shares of new for each share held. Thus $3,000,000 new common will be outstanding. In addition the stockholders authorized the company to sell a maximum of 50,000 shares of new common at not less than $100 a share to employees of every grade. The company will begin dividends on the new common at the rate of $4 a year, which doubles the income of present stockholders. The shareholders authorized the company to set aside $1,000,000 for a fund to be used for insurance of employees, care of dependents, a pension plan, or such other welfare work as the directors shall determine.

The $5,000,000 preferred stock has been underwritten by the Cleveland Trust Co., the price to net the Firestone company par.

Dolbeer Willys-Overland Treasurer

TOLEDO, OHIO,, Nov. 9—F. K. Dolbeer has succeeded Walter Stewart as treasurer of the Willys-Overland Co. Mr. Dolbeer was formerly with the financial department of the Victor Talking Machine Co. Mr. Stewart continues as a director.

—

King Raises Car Prices $50

DETROIT, MICH., Nov. 6—The King Motor Car Co. has raised the prices of its products. The sedan selling for $1,900 now sells for $1,950 and the seven-passenger touring car and the three-passenger roadster, both of which were $1,350, have been raised to $1,400.

The company announces that there may be an additional increase in the near future, owing to the constantly increasing cost of materials.

Steinmetz's Electric To Be Built

Dey Corp. To Build Lowest-Priced Electric for Utility and Other Uses

NEW YORK CITY, Nov. 8—The low-priced electric utility vehicle which Dr. Charles Steinmetz, engineering authority of the General Electric Co., has been advocating for several years seems near the point of realization. Such a vehicle will be manufactured by the Dey Electric Corp., with offices at 45 Broadway, N. Y. This concern has engaged show space for the Grand Central Palace show, New York, where these new electric vehicles will be on display, and it is planned to have production under way for the 1917 market.

A comprehensive line of what is described as the lightest, lowest-priced and highest efficiency electric vehicle ever built will be manufactured. The Dey company has secured a factory in the Metropolitan zone, and will specialize on a runabout intended primarily for utility work, such as solicitors, etc. The car is not a passenger type, nor yet a truck, but essentially a utility vehicle. In addition to this runabout a closed type of passenger vehicle will be produced. The company will manufacture what might be termed a utility chassis suitable for taxicab purposes, as well as passenger bodies and light truck uses.

That the designs of this lowest-priced electric are practically completed is apparent in that the cars will be at the New York show. That the company will go forward with an interesting manufacturing program is also apparent in that it is strongly financed and presumably closely connected with one of the large electrical manufacturers.

The dream of the $500 electric, as it

Injunction Holds Up Ford Profits

Dodge Bros., in Suit, Seek to Prevent Investment of Surplus Money

DETROIT, MICH., Nov. 3—A temporary writ of injunction against Henry Ford to restrain the Ford Motor Co. from distributing and investigating as fixed capital assets surplus profits that would otherwise be available for dividends, was issued in the Wayne circuit court yesterday.

The plaintiffs, John F. Dodge and Horace E. Dodge, stockholders in the company and also owners of the Dodge Bros. automobile plant, want the accumulation of cash surplus in the form of special dividends.

The cause of the writ, according to the Dodge bill of complaint, was the declaration by Mr. Ford at the end of the last fiscal year, that no special dividends would be declared in the future by the company and that surplus earnings would be used to extend the business.

The announced policy of Mr. Ford to engage in a multiplicity of undertakings was declared in the bill to be reckless in the extreme and to jeopardize seriously the interests of the stockholders. The bill states that Mr. Ford is engaged in negotiations to invest several million dollars in iron ore mines in Northern Michigan or Minnesota, to build ships transporting ore to smelters and to erect steel manufacturing plants, "thereby depriving stockholders of fair and reasonable returns upon their investment."

Mr. Ford owns 58 per cent of the capital stock of the Ford Motor Co. The authorized capital stock was placed at $2,000,000 in 1908. John F. and Horace E. Dodge each held 1000 shares par value $100 at that time. The Dodge Bros. contend that though the regular monthly dividends—5 per cent, or 60 per cent a year—are large on the $2,000,000 capital stock, the dividends amount to only a fraction of 1 per cent of the capital actually invested when the surplus is taken into account. They also allege that they have been unable to make any arrangements to discuss the plan with Mr. Ford and that he claims that since the profits are to be represented by investments in plants and capital, the stockholders should have no right to complain.

The defendants will be given a hearing to show cause why a permanent injunction should not be granted.

Ford Replies to Charges

The present plans of expansion contemplated by the Ford Motor Co. are only in accordance with the past policies of the company. Dodge Bros. have drawn $5,571,500 in dividends from an investment of $10,000 and still have holdings valued at $50,000,000. Political motives are behind the suit against the Ford company. These are statements by Henry Ford and his attorney Alfred Lucking in their replies to the suit instituted by Dodge Bros.

"At the founding of the Ford business," said Mr. Ford, "Dodge Bros. invested $10,000, but I don't think any of it was in cash. That was in 1903, and since then they have drawn out dividends amounting to a total of $5,571,500 in cash. Of course, they still have a 10 per cent interest in the business that is worth, on their own valuation, $50,000,000. Besides that during the life of the company we have paid them more than $27,000,000 in cash for material and parts made for us, on which I believe they made a profit of at least $10,000,000. It is on the profit of these payments and their dividends drawn from the Ford Motor Co. that their present fortune is built."

Mr. Ford made light of the allegation in the Dodge bill of complaint that his proposed expansion would injure them.

—

Velie Companies May Consolidate

MOLINE, ILL., Nov. 6.—A special meeting of the stockholders of the Velie Motor Vehicle Co. will be held Nov. 14 at Moline, Ill., to consider a proposition to consolidate with the Velie Engineering Co. under a single corporation under the style Velie Motors Corp., with a capital stock of $2,000,000.

—

Madison Motors Acquires Anderson Plant

ANDERSON, IND., Nov. 3—The Madison Motors Co., this city, has consummated a deal for the acquisition of the buggy and wagon plant of the Anderson Carriage Co. This plant will be known as the Madison plant No. 2, and is to be used for manufacturing and finishing bodies and tops as well as final assembly. Plant No. 1, the old Rider-Lewis building, later occupied by the Nyberg company, will be used for chassis manufacturing and assembly only. The addition of the Anderson carriage plant gives the company additional floorspace of about 175,000 sq. ft.

—

Woodard Resigns from N. J. Car Spring

JERSEY CITY, N. J., Nov. 6—S. P. Woodard has resigned from the New Jersey Car Spring & Rubber Co., this city. He has been for the past 2 years general and sales manager of this company. He will not be actively connected with the company in the future.

His immediate plans are uncertain. It is rumored that he is negotiating with a large western tire manufacturer and may handle the entire output of mechanical rubber goods and tires.

United Motors Buys Houk Co.

Ninth Company To Be Taken Over—Management Will Remain Unchanged

BUFFALO, N. Y., Nov. 6—The Houk Mfg. Co., maker of Houk wire wheels, has been purchased by the United Motors Corp., which brings the total number of concerns owned by this corporation up to nine. As with its previous purchases the Houk company will continue as a separate manufacturing organization, and George W. Houk, founder of the Houk company and the one person in the U. S. A. responsible for the present status of wire wheels, will continue as manager.

As with other properties purchased by the United Motors, the Houk Mfg. Co. will be largely increased. There are 500 men at present on the payroll but this number will be increased by 300 at once. Previous to Nov. 1 the capacity was 1000 wheels per day, but it is now up to 2200, and it will be 4500 per day by Feb. 1, according to present plans.

Approximately $1,000,000 will be expended on new buildings and equipment, the work connected with which will be started at once. The capacity of the plant will be doubled.

The progress of the wire wheel in America has been almost entirely connected with the name of George W. Houk. His work in this country started as a licensee of the Rudge-Whitworth company of England. He started manufacture Sept. 23, 1913, and first deliveries were made in February, 1914. To-day the company has an account with eighty-five different car makers, and during the last 12 months has averaged approximatelly 800 wheels per day. The company is at present manufacturing 40 per cent of the wire spokes used in its wheels. The spoke manufacture was started in March, 1915, when Houk purchased the American Spoke and Nipple Co., of Detroit, and moved the factory to Buffalo.

The month of October was the largest month in the history of the company. Total shipments were 19,461 wheels. On Oct. 24 unfilled orders on the books of the company totalled 197,205 wheels.

—

M. A. M. Annual Banquet Jan. 10

NEW YORK CITY, Nov. 3—The Motor and Accessory Manufacturers will hold their annual banquet at the Waldorf Astoria Hotel, this city, on Jan. 10. W. M. Sweet, former manager and now assistant to the president of the United Motors Corp., has been elected chairman of the banquet committee.

Fisher Body Buys Regal Plant

Also Adding Two Buildings Costing $260,000 and $225,000 —In Operation Next May

DETROIT, MICH., Nov. 2—The Fisher Body Corp. has purchased the factory of the Regal Motor Car Co. located opposite the main Fisher plant here. The Regal unit is already in active operation and with this additional capacity, the Fisher Co., it is stated, is now turning out about 60 per cent of all the closed automobile bodies being made in the United States.

Notwithstanding the increased production the corporation was not able to accept contracts recently offered them to furnish bodies to two of the large producers and therefore is adding to its already extensive plant in Detroit two large buildings, one costing $260,000 for general body construction and one costing $225,000 for service and repair departments, both of which will be in full operation next May.

Charter Oak Car Under Way

HARTFORD, CONN., Nov. 6—The Eastern Motors Syndicate, organized some time ago for the development of a high-grade automobile, has the designing work well advanced and plans are practically completed for construction of a building to meet the manufacturing requirements. The car will be known as the Charter Oak in honor of the city of Hartford, where the famous tree was located. The manufacturing organization will be known as the Eastern Motors, Inc., which will take over the present syndicate and has been incorporated for $1,000,000.

Ricker Heads Ricker Oil Co.

INDIANAPOLIS, IND., Nov. 7—Chester S. Ricker, consulting engineer, was elected president of the Ricker Oil Co., which was recently incorporated at Indianapolis. Associated with him are S. H. Penfield, vice-president of the Sakusvyrt Wheel & Mfg. Co., Jamestown, N. J., and president of the Peru Auto Parts Mfg. Co., Peru, Ind., as vice-president and Robert B. Denham of Indianapolis as treasurer.

Chalmers Motor Corp. Chartered

ALBANY, N. Y., Nov. 3—The Chalmers Motor Corp. formed last week to succeed the Chalmers Motor Co. as a result of the refinancing of the company, has filed articles of incorporation here. The company has 600,000 shares without par value. The directors are Benoni Lockwood, F. A. Gaynor and R. G. Goad, of 43 Cedar Street, New York City.

The Chalmers stock is now on the Curb market, having been offered by J. S. Bache & Co. and C. D. Barney & Co. at $35 a share. Common shareholders, according to the new financing plan, will receive for each share held four shares of the new, while preferred shareholders may have their shares redeemed at $115 or exchange on the redemption basis, about 3½ shares of the new for each share held. The new corporation will keep 135,000 shares in the treasury and use 200,000 shares for exchange purposes. Net proceeds of the 265,000 shares offered, or more than $9,000,000, will go into the treasury.

International Motors Co. Reorganization Plan Is Approved

NEW YORK CITY, Nov. 6—The reorganization plan of the International Motors Co. has been approved by the stockholders and creditors, over 93 per cent of the preferred and 94 per cent of the common being deposited with the two committees. A reorganization plan was adopted in September by which a new company of the same name will be formed to take over the present concern. Additional capital of $1,500,000 was raised and the $2,881,000 notes maturing the first of this month was obliterated.

By this plan the new company's securities will be exchanged on an equal basis for those of the present organization and will consist of $4,381,000 in 7 per cent cumulative first preferred stock, $2,723,000 second preferred and 53,638 shares of common of no par value. Of the first preferred, $2,881,000 is to go to the holders of the notes at par, and the balance will be issued for cash to provide working capital, being offered to stockholders at par with common stock thrown in. Holders of the present $3,600,000 preferred will receive 60 per cent in new second preferred and 10 per cent in new common. For the outstanding $5,628,000 common, 10 per cent in second preferred and 10 per cent in new common is to be exchanged.

Rochette Sails for S. A.

NEW YORK CITY, Nov. 4—Edward Rochette, special representative of the Willys-Overland Co., sailed to-day on the steamer "Pastores" for South America by way of Panama Canal and the West Coast. His destination is Valparaiso, Chile. Mr. Rochette has represented Willys-Overland for some years in the South American field, where he makes headquarters at Buenos Aires.

Winckler with Pittsburg Engine

RACINE, WIS., Nov. 6—A. E. Winckler, formerly chief engineer of the automobile department of the J. I. Case T. M. Co., Racine, has become chief engineer of the Pittsburg Model Engine Co., Pittsburg.

S. K. F. Controls Hess-Bright?

Control of Conrad Ball Bearing Patent License Royalties a Part of Transaction

NEW YORK CITY, Nov. 8—Control of the Hess-Bright Mfg. Co., Philadelphia, Pa., manufacturer of ball bearings, has been secured, it is rumored, by the same financial interests that own the S. K. F. Ball Bearing Co., Hartford, Conn. It is understood that over 50 per cent of the Hess-Bright stock has been secured by the latter concern. No statement has been issued by the S. K. F. company. It is assumed the Hess-Bright factory in Philadelphia will be operated as formerly, and perhaps on an increased scale.

Conrad Patent Included

With the purchase of the Hess-Bright company goes the now celebrated Conrad patent, which was adjudicated in the courts a year ago and which patent has been a valuable asset of the Hess-Bright company. This patent refers to an annular type of bearing in which the balls rotate in a groove presenting a continuous surface. Several bearing concerns have been licensed by Hess-Bright under this patent, these including: New Departure Mfg. Co., Standard Roller Bearing Co. By securing control of the basic patent the S. K. F. Ball Bearing Co. will receive all royalties accruing therefrom. These royalties are a large figure at present and will naturally increase with the greater development of the industry.

Republic Truck Shipments Gain

ALMA, MICH., Nov. 3—Shipments of the Republic Motor Truck Co. in October amounted to 626 trucks, compared with 190 in 1915 and thirty-five in 1914. For the first 10 months of this year the shipments were 4902 trucks, against 1442 in the corresponding period of last year.

Commercial Auto Body Co. Formed

BAY CITY, MICH., Nov. 1—The commercial Auto Body Co., this city, has been formed to manufacture commercial bodies for Fords. The incorporators are W. B. Fitzgerald, Henry Kinney, Robert Woodworth, A. E. Hubbell, Adam Schepper, Edward Covert, W. P. Kavanagh and W. H. Kelly.

Gasco Mfg. Co. Organized

LANCASTER, PA., Nov. 1—The Gasco Mfg. Co. has been formed in this city to manufacture specialties for Fords. R. W. Shreiner is president and general manager. One of the articles to be manufactured is a new cowl dash light for Fords. This company will also put out a new heater for Fords.

Supreme Court Hears Tax Case

Arguments Heard in N. J. Test on Legality of Taxing Non-Residents

WASHINGTON, D. C., Nov. 8—Whether a State can tax an automobilist from another State for the use of its roads will be decided shortly by the United States Supreme Court, the argument for the so-called New Jersey test case prepared by the American Automobile Assn. and the National Automobile Chamber of Commerce having been presented Oct. 31. The case is that of Frank J. Kane against the State of New Jersey, based on his interstate journey from New York to Pennsylvania, which resulted in his being convicted and fined for violating three provisions of the New Jersey law, first that he had failed to register his car in New Jersey; second, that he failed to pay the tax imposed on non-residents; and third, that he failed to file with the Secretary of State a power of attorney.

The American Automobile Assn. was represented by John W. Griggs, former attorney general of the United States, and Charles Thaddeus Terry appeared for the N. A. C. C. The argument presented by them set forth these contentions:

1—It being admitted in the record that the fees charged for the operation of automobiles over the highways of New Jersey result in a large surplus revenue to the State over and above the expenses of examination, licensing, registering and inspecting the automobile traffic on the highways, the charge is a tax which is not in conformity with proper tax laws in that the motor vehicle is burdened with a heavy impost, irrespective of its value, whereas other property is taxed only according to its value.

2—The so-called "license-fee" being in reality a tax, is unreasonable and void as such tax because even assuming that it is a charge for the use of a special facility, to wit—the improved roads furnished by the State of New Jersey, it is unreasonable because a lump sum is charged irrespective of the question how much or to what extent the automobile uses the roads. For example, the same fee is charged for the right of the automobile to go a few hundred yards, as is charged to the automobile which traverses the roads of the State for a whole year covering thousands of miles. Thus the charge is unequal, disproportionate and not upon any scientific or logical basis, and, therefore, improper and illegal.

3—The improved roads of a State are not a "special facility" afforded by the State to automobiles, but their construction and presentation to the public are simply governmental functions which should be paid for out of the general tax fund in the same way that the police force and the fire department are afforded for the use of all the citizens irrespective of the amount of use. Therefore, no special charge or impost can be levied for their use to any particular class of users.

4—That the law is discriminatory and class legislation in that even assuming that the license fee is a charge for the use of the roads, it is not imposed equally upon all the users of the roads. Horse-drawn vehicles use the roads and use up and destroy the roads in a large degree, and, therefore, if the tax were to be an equal and uniform tax, it must be imposed upon horse-drawn vehicles as well as upon automobiles.

5—The requirement that before any non-resident shall use the highways of the State, he must file a power of attorney with the Secretary of State, and authorize such secretary to receive service of process for him, is ousting him of his domicile and imposing a requirement which is not imposed upon any other class of non-resident citizens of the United States going into the State of New Jersey. It is assuming in advance that the automobile user is likely to commit a criminal act which is absurd on the face of it. He is no more likely to commit a criminal act than any other non-resident entering the State of New Jersey, and even if he were, such a method of enforcing the criminal law is unknown to our jurisprudence.

6—The requirement of a power of attorney from non-residents and the imposition of a tax upon non-residents and the requirement that before the highways shall be used by non-residents they shall make application and take out registration, are burdens on interstate commerce which the Constitution of the United States forbids under the Fourteenth Amendment thereof.

It is expected a decision will be rendered by the court before the holiday recess.

Ypsilanti Motor Truck Co. Organized

DETROIT, MICH., Nov. 6—Stockholders of the Globe Motor Truck and Body Co. met Nov. 3 and organized the Ypsilanti Motor Truck Co. with a capitalization of $100,000.

The board of directors includes: H. R. Scoville, Charles N. Haviland, D. L. Davis, F. W. Paton, Frank R. Welsh, H. F. Shaefer and Gilbert E. Porter, all of Ypsilanti. A factory will be built.

—

Steinmetz Electric To Be Built

(*Continued from page* 785)

was styled 2 years ago, has been a cherished matter with Dr. Steinmetz. It has been known for several years that he has been perfecting features of design which would make it possible to produce a utility electric vehicle at practically the same price as the cheaper gasoline machines. Dr. Steinmetz strongly advocated this type of vehicle before the different electric interests, as well as before the electric vehicle manufacturers. It was generally considered impossible to build such a vehicle that would give the desired service. The possibility of producing such a vehicle resulted in many strenuous arguments on convention floors, between central station concerns, or companies manufacturing electric current, and those engaged in vehicle manufacture. The central station interests were strong for such a vehicle, as it would naturally be a great source of revenue if manufactured in large quantities. On the other hand, electric vehicle makers were catering to public requirements for larger and more luxurious types of electric vehicles.

The price of the new lowest-priced electric to be built by the Dey corporation has not been determined, but it is understood that it will be under $1,000 and that eventually the dream of Dr. Steinmetz for a $500 vehicle may be attained, if not carried further.

—

$9,000,000 for Freight Cars by M. C.

DETROIT, Nov. 3.—The Michigan Central Railroad has just closed a contract for the construction of 6750 freight cars, of which 4000 will be cars equipped for carrying automobiles.

Overland Convention in Dec.

Co. Will Be Host to 4000 Dealers of U. S. and Canada

TOLEDO, OHIO, Nov. 4—December is to be the month for the grand welcome to the 4000 Overland dealers of the United States and Canada, and plans are now being formed to make it an epochal month in the history of the big Willys-Overland organization. Beginning about Dec. 4 and ending Dec. 23 there will be a series of gatherings of the Overland dealers here. It is planned to make it the biggest event of its kind ever held in the automobile industry.

Entertainment in Relays

The country is being divided so that the agents from one section will follow those of another every few days until the entire organization has been entertained. Each division will spend about 2 days and 3 nights in the city, and there will be visits to the factory and talks in the new administration building.

President John N. Willys plans to be on hand, so that he may have a chance to talk to all his dealers and give them some word of encouragement for the forthcoming season. At that time he will be ready to announce what the production is going to be, and if there is to be any change in the style of models, prices, etc. From the factory no inkling has been given out as to any proposed announcements, but it would not surprise many of the dealers if new models or new prices were planned, and they were let into the secret just before the big shows, so that they could begin their operations for the new year.

The factory will be the host of the visiting dealers while they are in this city, but the men will pay their own fares to and from their homes. It has been arranged that the dealers will get the benefit of excursion rates.

—

Kuhn Is Four-Wheel-Drive Tractor

SEATTLE, WASH., Nov. 4—The Kuhn Tractor Truck Co. has been organized here to manufacture a tractor truck, the chief feature of which is that each wheel operates independently of the other. It has a four-wheel drive and power may be applied to all wheels or to each one. There is a positive power control and some of the wheels may be buried in the mud, but the power can be applied to the free wheels alone and no slipping results. The truck is in this way pulled out of difficult positions. A four-wheel brake is another unique feature which equalizes the tension on all wheels at the same time.

127 New Accessory Exhibits

—

Makes Total of 340—Every Inch of Space Taken—Car Space All Filled

NEW YORK CITY, Nov. 8—The Motor and Accessory Manufacturers, which recently allotted space in the national automobile shows to 115 members, has added 127 concerns not members of the association. With ninety-eight car exhibits, the total reaches 340. Every inch of available space for both the local and Chicago national shows has been allotted. For the first time in the history of the national shows all the space allotted to automobile exhibitors has been filled, and at the first drawing.

The new accessory exhibitors follow:

Brewster & Co. Joins N. A. C. C.

NEW YORK CITY, Nov. 6—Brewster & Co., Long Island City, carriage builder, and which 2 years ago began the making of a car with a Knight engine, has been admitted to membership in the National Automobile Chamber of Commerce.

Time Payment Plan for Trucks

—

Guaranty Securities Corp. Method Is Similar to Passenger Car Scheme

NEW YORK CITY, Nov. 6—A time-payment plan for truck sales has just been adopted by the Guaranty Securities Corp., which about a year ago entered the field to finance the sale of passenger cars by dealers. The new plan is similar to the passenger car plan, which was described in THE AUTOMOBILE for April 6, but the percentage of cash demanded is not so great because the truck is strictly a necessity and pays for itself.

The status of the Guaranty business may be surmised from its statement that since Jan. 1 it has financed $18,000,000 of passenger car business. The truck plan has been in operation but a few days.

Collects 25% Cash

For a general understanding of the plan it may be stated that when the dealer sells a truck he collects 25 per cent cash from the customer and is paid nearly all the balance by the Guaranty corporation, which collects from the truck buyer through notes. For handling and for adequate insurance a Guaranty charge is made and is paid by the truck buyer. A small part of the sales price of the truck is retained by the Guaranty corporation until the buyer's notes are all paid, but on his deferred payment the dealer gets the prevailing rate of interest.

When a dealer sells a truck of which the f.o.b. factory list is $1,200 the dealer adds freight and the Guaranty charge in arriving at the "Buyer's Delivered Price." This Buyer's Delivered Price is the basis of figuring. It is as shown in the plan outlined in the table on page 795.

Several terms in the plan may require explanation as may also some of the steps.

Delivered Price to the truck buyer consists of the list price of the truck, including body and chassis, the freight from the factory to the dealer and the Guaranty charge. If the truck is an electric the delivered price may include the battery provided the Guaranty corporation approves of the make of battery. This, in effect, means that the battery may be included if it is supplied with the truck as shipped from the factory.

Guaranty Charges are approximately 3 per cent, but for convenience in figuring the prices of trucks have been graded in units of $250 and a flat price arrived at for each class, as is shown by the table of charges on page 795.

(*Continued on page* 795)

120,000 Cars in Canada

Ontario Leads with 50,000—100,000 Cars To Be Produced There in 1917

TORONTO, ONT., Nov. 3—Government registration returns indicate that there are approximately 120,000 cars owned in Canada to-day—an increase in round figures of 45 per cent since a year ago. Ontario with approximately 50,000 cars, maintains her position as the banner automobile province of the Dominion, as in Ontario are owned more than three times the number of cars owned in any other province, and approximately 42 per cent of all the cars in the Dominion.

This large increase in the number of cars in Canada is primarily attributable to two things. The first is, of course, national agrarian, industrial and commercial prosperity, and in the second place to the inauguration in Canada, only now getting under way, of the aggressively progressive intensive car merchandising methods long since successfully in operation in the States.

With every facility to speed this development, Canada has over 400,000,000 acres of fertile wheat land awaiting cultivation—the only great arable tract of land undeveloped in the world under salutary democratic government.

The automobile plants of Ontario will build during the coming year over 100,000 cars, according to their production schedule.

—

Pennsylvania Fees for Good Roads?

PHILADELPHIA, PA., Nov. 3—Announcement was made by Governor Brumbaugh, of Pennsylvania, at the opening exercises of the new William Penn Highway at Easton, that a hill would be submitted to the next Legislature providing that all money received by the State from licenses will be turned over to the highway department for new highways. He also announced that the bill would provide for an annual contribution by the State of $5,000,000 for that purpose. The William Penn Highway which was dedicated runs from Pittsburgh to Easton.

—

Canada Uses 30 per Cent More Gasoline

KINGSTON, ONT., Nov. 4—According to U. S. Consul Felix S. S. Johnson at Kingston, the consumption of American gasoline in Canada this year has been greater than ever before. To date the amount used is 25 to 30 per cent larger than last year. In the average year the consumption in Canada is about 60,000,000 gal. With an increase of 25 per cent the consumption this year will be about 75,000,000 gal. Throughout the period of high prices gasoline has been cheaper in Ontario than elsewhere.

For the purposes of comparison with Canadian prices the imperial gallon must be used as a basis. This is one-fifth larger than the wine gallon and would bring the American price to 27.6 per gal. To this must be added the duty of 2.5 cents per gallon and freight to the amount of 1.25 cents per gallon. This would bring the cost of Canadian gasoline to 31.35 cents per gallon from tank to garages. The war tax of 7½ per cent is also levied. There are indications that present war prices will go down as a result of poor weather and the increased production of crude oil.

—

New Parking Law for Baltimore

BALTIMORE, MD., Nov. 4—Baltimore's new automobile parking law went into effect last week and scores of automobilists were arrested in all parts of the city.

The law requires that no vehicle of any kind be left standing on any streets during the day longer than 2 hr. at a time, nor longer than 3½ hr. at night. The biggest objection raised against the ordinance is that it affects unfrequented streets of the city as well as those on which the traffic is heavy.

—

Waukesha Motor Promotes Industrial Education

WAUKESHA, WIS., Nov. 4—A unique plan for the promotion of industrial education has been evolved by the co-operative effort of the Waukesha board of industrial education and the Waukesha Motor Co., motor manufacturer, with the approval of the Wisconsin State board of industrial education. By this plan it will cost the city only a nominal sum for high class instruction, and no investment or upkeep for facilities is required. The Waukesha Motor Co. has permitted the local board to establish a school organization directly within its big plant. The school is open to any person who qualifies by being 16 years of age or over. Part of the time during each day will be devoted to actual teaching and instruction related to the general problem of gas engineering, while the remainder of the day will be devoted to the teaching of citizenship and to diversified employment within the factory itself. Enrollment is open to any young man, whether at present employed by the Waukesha Motor Co. or not, and full wages will be paid for the time devoted to schooling, the same as for employment.

—

Pennsylvania License Fees $2,301,240

PHILADELPHIA, PA., Nov. 3—Up to Oct. 30, the Pennsylvania State Highway Department received $2,301,240 in license money. For the entire 12 months of 1915 the amount was $1,650,000.

Mass. Registrations Gain 31,000

113,786 Passenger Cars—17,682 Trucks—8864 Dealers' and Makers' Cars

BOSTON, MASS., Nov. 4—Registration figures in Massachusetts continue to set new records and the Highway Commission has announced that for the first 10 months of this year the relative proportion of increase has been greater than in the past 2 years. Up to Nov. 1 there were 113,786 passenger cars, 17,682 commercial vehicles and 8864 cars belonging to manufacturers and dealers. This gives a total of 140,332 machines. There were 162,046 licenses issued and the receipts have run up now to $1,537,737. These figures exceed expectations. The figures show a gain of some $300,000 in fees over the same time a year ago, and something like 31,000 more cars. The following table gives the comparative figures for the same periods for the past 3 years:

	1916	1915	1914
Automobiles ...	*181,468	†100,500	‡76,145
Manufacturers or dealers....	1,966	1,732	1,514
Licenses, operator and chauffeur ...	55,045	42,325	25,651
Operator and chauffeur renewals	107,001	85,865	70,166
Examinations .	11,179	9,693	.....
Total receipts..	$1,587,237	$1,189,010	$916,712

*Includes 17,682 commercial vehicles.
†Includes 11,564 commercial vehicles.
‡Includes 8,078 commercial vehicles.

—

Automobile Telegraphic Code on Market

SAN FRANCISCO, CAL., Nov. 6—The Code Publishing Co. has placed on the market a standardized automobile telegraphic code which is the work of Robert E. Pye. The book has been endorsed by the National Assn. of Automobile Accessory Jobbers, which recommends its use. The code is divided into three divisions: Merchandise, in which is coded supplies, accessories and car models; general phrases, covering orders, shipping, prices, general communications, etc.; the third division is tables of measurements, money, transportation, etc. The book will be distributed by Commissioner W. M. Webster of the N. A. A. A. J., Chicago.

—

Engel to Promote Oldsmobile Sales

LANSING, MICH., Nov. 6—J. W. Engel has been appointed manager of the sales promotion department of the Olds Motor Works. Before entering the automobile field Mr. Engel was in newspaper work and for several years filled an executive position with the U. S. Postal Service.

Para Needs More Good Roads

Gaidzik, Representing Nash in S. A., Finds Little Future Without Them

NEW YORK CITY, Nov. 4—George W. Gaidzik, South American representative of the Nash Motors Co., arrived in this city yesterday after a 10 months' business trip along the East Coast of South America, where he has been establishing agencies and demonstrating the Jeffery Quad and the Jeffery passenger car. During his recent trip Mr. Gaidzik has spent most of his time in Buenos Aires, Montevideo, Sao Paulo, Rio de Janeiro, Bahia, Pernambuco, and the two Amazon cities, Para and Manaos. Speaking of the present possibilities of automobiles in the Amazon valley, Mr. Gaidzik does not look for a big future of either of the cities of Para or Manaos. From 5 to 10 years and perhaps more may be necessary to get the road-building movement started. Para, near the mouth of the Amazon, is a city of 150,000 with 200 automobiles. Of these seventy-five are privately owned vehicles, and the remainder are in taxi service. Motor trucks have made little progress in this city, there being only five trucks most of which are used in the brewery industry. To these must be added delivery wagons used by the large stores, which are not very numerous.

As in the majority of South American cities, the streets of Para are well paved with stone block, a good surface for motor use. The trolley tracks are, however, used almost exclusively. Cars for this city should have right-hand steering, although left-hand will do. The rules of the road in Para are the same as in the U. S. A. The 56-in. tread is satisfactory.

Manaos a Rubber City

Once the streets of Para are left there are no roads with the exception of dirt trails in the immediate outskirts of the city. The country is fairly level but generally covered with forest. There being little cultivation surrounding the city there is naturally no market for cars outside of the city limits.

The city of Manaos, like Para, is essentially a rubber city, but located well up the Amazon. With a population of over 100,000 there are about 100 automobiles in the city, a quarter of which are in use. To these must be added three or four motor trucks in the service of breweries and ice companies. You can use an automobile on the streets of the city and on the outskirts but once you are beyond these, the forest begins and all use of a car ends. The city streets in Manaos are paved with stone blocks as in Para.

In both of these rubber cities of the Amazon, the odor of crude rubber is omnipresent. There is a constant teaming of it in the city from dock to warehouse. Both cities are well provided with hotel accommodations. In Para there is a five-story hotel which ranks with any in South America. It is being added to at the present time. The hotel accommodations at Manaos, while not so extensive, are quite satisfactory.

The population in both of these rubber cities is largely Portuguese. There is a good sprinkling of English. All of the poorer classes are black.

Automobile imports in these Amazon River cities, according to figures from the Brazilian government, are as follows:

Port	1910	1911	1912	1913	1914	1915
Manaos	32	31	29	24	5	0
Para	72	76	61	58	14	0

Security Co. to Finance Dealers

ST. PAUL, MINN., Nov. 2—The Security Mortgage Co., this city, has been formed with a capital of $1,000,000 to finance automobile and truck sales here. It has taken headquarters in the New York Life Building and will begin business at once. G. N. Michaud will be in charge of the office.

J. N. Storr, president of Kuhles & Stock Co. is president; A. Hirschman, vice-president of the People's Bank, is vice-president; N. P. Rogers of Rogers & Rogers, live stock dealers, is treasurer and G. N. Michaud, secretary and general manager.

Two New Jeffery Sedans

KENOSHA, WIS., Nov. 6—The Nash Motors Co., this city, has brought out two new Jeffery sedans in four- and six-cylinder seven-passenger types, the tops being removable for summer touring. The large French plate windows drop 5 in. for ventilation in warm weather, the rear window measuring 19½ by 31 in. Divided front seats eliminate the necessity of fore doors and thus do away with the need for a panel between the front window and the rear door. Upholstery is gray whipcord and there are roll curtains on the windows.

Cassidy Handling Corning Conaphore

NEW YORK CITY, Nov. 6—The Corning Glass Works, Corning, N. Y., has appointed the Edward A. Cassidy Co. as sales division for the Corning Conaphore, a new device for giving the right direction and long range to automobile headlights, and for eliminating glare. It is made in white glass and patented Noviol yellow tint glass, which eliminates the violet-blue rays, enabling the light to penetrate fog and dust and does away with back glare.

Canadian Farmers Prosperous

High Price of Wheat Stimulates Sale of Automobiles to Rural Population

TORONTO, ONT., Nov. 3—Using the wheat quotations of the week as a barometer, the automobile manufacturers who sell machines to the farmers of western Canada find the outlook most gratifying. December wheat was quoted at $1.90 last week, nearly twice the figure of some seasons. Canada's war crop of wheat is yielding handsome profits to the farmers, which leads W. P. Hinton, traffic manager of the Grand Trunk Pacific Railway, to measure prosperity in terms of automobiles owned, and cars bought, in the present year.

"Farmers are exceedingly prosperous," he states, "and their purchasing power was never so great."

"Perhaps a striking illustration of this fact," declares the railroad man, "is that approximately $2,000,000 more than in any other year has been expended by the rural population in the purchase of automobiles. In fact, the automobile seems to have become a farm necessity, and even if we are disposed to consider it an extravagance, it certainly adds to the joy of living in the agricultural districts of Canada."

Racine Tire Branch Managers Meet

RACINE, WIS., Nov. 4—The Racine Auto Tire Co., this city, which already has announced plans for a new plant involving $100,000 or more, entertained its branch managers and salesmen at a convention at the present factory for two days last week. The policies of the company and plans for the disposition of the 1917 output were discussed. Managers of the branches at Chicago, Milwaukee. Minneapolis and Des Moines were present.

Selden Division Managers in Conference

ROCHESTER, N. Y., Nov. 6—The first conference of division sales managers and prospective division managers of the Selden Truck Sales Co., this city, under the regime of Sales Director H. T. Boulden, was held Nov. 2, 3 and 4.

Mr. Boulden presided, being assisted by President Geo. C. Gordon, Vice-President Wm. C. Barry, Jr., and Secretary R. H. Salmons.

Representatives in attendance were George S. Holvey, home office sales department; E. W. Templin, Chas. N. Gillette, Southeastern representative; Chas. E. Collard, Atlantic Coast representative; Wm. C. Barry, Jr., general manager, Selden Motor Vehicle Co.; Edward F. Drew, Middle West representative; Paul B. Donaldson, Northwest representative; W. E. Dugan, factory manager; H. T. Boulden, sales director; J. E. Morse, New England representative; C. L. Du Puy, Southwestern representative; S. P. Gould, Rochester, and D. S. Everett, Pacific Coast representative.

Anderson Sales Gain 141 Per Cent

Car Shipments for 4 Months Increase 79 Per Cent Over 1915 Period

DETROIT, Nov. 4.—The Anderson Electric Car Co. had an increase in business amounting to 141 per cent during its fiscal year. Car shipments for 4 months of the current year have been 79 per cent greater than for a similar period in 1915, and it is expected that the company's business for the current year will be 100 per cent greater than last year. Directors elected are: W. C. Anderson, M. S. Towson, J. B. Book, Jr., G. M. Bacon, G. D. Fairgrieve, W. M. Locke, W. P. McFarlane, W. H. Murphy, F. E. Price. The directors elected officers as follows: W. C. Anderson, president; M. S. Towson, vice-president; G. D. Fairgrieve, vice-president and assistant treasurer; W. P. McFarlane, secretary and factory manager; W. M. Locke, treasurer; F. E. Price, assistant treasurer; Wilson Oritzer, assistant secretary.

Studebaker Earns $8,140,420

DETROIT, Nov. 3.—The Studebaker Corp. reports net profits for the 9 months ending Sept. 30 amounting to $8,140,420. The net profits for the same period in 1915 were $7,082,479.

Practically all of the net profits this year were from domestic business, as total net profits from war orders were $154,000, as compared with $3,140,000 realized on war orders last year.

—

70 Per Cent of Gasoline Pumps Tested Found Inaccurate

WASHINGTON, D. C., Nov. 6—The Bureau of Standards has in circulation report No. 81 on liquid measuring-pumps for selling gasoline. The report, in addition to a description of the different systems, gives results of some inspections having to do with the accuracy of these pumps.

Of seventy-nine measuring systems of various types chosen at random and tested in a number of different cities, fifty-five, or 70 per cent, had errors in excess of the tolerance allowable, and twenty-four, or 30 per cent, had errors within the tolerance. In addition, there were eight outfits so constructed as to be absolutely unsuited for retail liquid dispensing.

Of the fifty-five out of tolerance 80 per cent gave deliveries in deficiency and 20 per cent in excess. This tendency toward deficient measurement is worthy of careful consideration, and it is only proper to call attention to the fact that most of the causes of error in measuring-pump operation tend toward the side of deficient delivery. Among these may be mentioned leaks, retention of liquid by the hose. excessive virtual suction head, resulting in vaporization and other losses, failure to complete the full stroke and slippage.

Materials Markets Steady

NEW YORK CITY, Nov. 8—The automobile materials' market was steady last week, very few price changes taking place. Steel, copper, aluminum, and lead, remained constant. Ceylon rubber was 3 cents higher per pound, reaching 60. Tin rose to $42.33 1/3 per 100 lb., a net rise of 45 cents. Cottonseed oil declined 60 cents per barrel to $11.80. The rest of the materials were unchanged and steady, as shown in the accompanying tabulation.

It is estimated that 80 per cent of the copper production for the first 6 months of 1917 has been sold, indicating that approximately 900,000,000 lb. of copper have been placed on the producers' books for delivery during the period from Jan. 1 to June 30 next.

Security Prices Are Higher

Tire Issues Strong—Much Buying on Margin—Further Rise Expected

NEW YORK CITY, Nov. 8—The usual heavy buying and selling before Election Day occurred on Monday. The market was mostly bullish, the majority of buyers predicting a rise after Election Day. As a result of this heavy buying prices of many issues rose. Much pressure was brought to bear on Ajax Rubber and United Motors, which went up 3⅞ and 2 points, respectively. General Motors, Chalmers, Firestone and Kelly-Springfield Tire, were also in demand.

General Motors common rose 10 points as did Chalmers. Chalmers preferred rose 7 points, one of the features of the week. This company announced a refinancing plan last week. Firestone Tire common rose 5 points to 1150, a record price. Kelly-Springfield Tire common rose 2½ points to 77½.

—

Hayes Wheel Co. Add $500,000

JACKSON, MICH., Nov. 6—The Haynes Wheel Co., this city, has increased its capitalization from $1,000,000 to $1,500,000. The increased fund will be used for additional machinery and equipment for the manufacture of wire wheels.

—

Newell Purchasing Agent for Hood

DETROIT, MICH., Nov. 3—R. B. Newell has joined the staff of the Wallace Hood Service Bureau as the purchasing agent. Mr. Newell was formerly connected with the Briggs Detroiter Co. as service manager.

—

Bate Predicts Higher Material Prices

DALLAS, TEX., Nov. 6—That automobile makers of the North and East are expecting an advance in materials that may result in higher cost of automobiles, was the statement expressed by John W. Bate, vice-president and chief engineer of the Mitchell Motors Co., in an address before Texas Mitchell dealers at Dallas last week. The address was given at a dinner tendered by H. T. Hays, district representative for the Mitchell company at the Adolphus Hotel. Other factory representatives who spoke at the meeting were: George W. Hipple, general merchandising counsel and F. W. Pelton, advertising manager.

—

Avery Tractor Maker's Capital $2,300,000

LOUISVILLE, KY., Nov. 3—B. F. Avery & Sons, manufacturers of gasoline trac-

tors in this city, have filed amended articles of incorporation fixing the capital stock at $2,300,000, against the old capitalization of $1,500,000. The $200,000 of 7 per cent series A preferred will be retired and a series known as A1 preferred, consisting of 7000 shares at $100, bearing 7 per cent, will be issued; another series of $600,000 preferred, paying 6 per cent, will be put out. There is a similar issue outstanding. There will be 10,000 shares of common of $100 each, as compared with 700,000 authorized at present.

—

S. R. B. Earnings Halt Reorganization

PHILADELPHIA, PA., Nov. 3—The earnings of the Standard Roller Bearing Co. during the past year have shown so much improvement that the proposed reorganization of the company, it is stated, has been practically abandoned. Net earnings for the year ended Sept. 30 last were $747,546.

There are outstanding $2,725,850 common, $572,750 7 per cent cumulative preferred of authorized issues of $4,000,000 common, $3,000,000 first preferred and $1,000,000 second preferred stock.

—

Fisk Ratifies Increase of Capital

CHICOPEE FALLS, MASS., Nov. 1—The Fisk Rubber Co., this city, has approved the increase in capital from $19,400,000 to $39,500,000 and extension of time for conversion of second preferred to common stock from Nov. 1, 1917 to Nov. 1, 1932.

Packard Continues Expansion

Many New Buildings—Numerous Machines Installed —Sociological Work

DETROIT, MICH., Oct. 27—Fourteen months ago the Packard Motor Car Co. ordered a bird's-eye view made of its plant. When it was finished it was found to be old compared with the number of buildings added after the photograph was taken. The company has endeavored three times since to secure a bird's-eye view, but always with the same result. The building construction has been so rapid and vast that each view is always one or two stories or buildings behind. It is quite likely that the view shown here, though finished as the story is written, will not include the structures that have been started or completed in the past few days. Demands for increased productive facilities have been so urgent that construction of new buildings cannot catch up with it.

During the past year, 6.6 acres of floorspace have been completed while 4 acres are under course of construction, making a total space of 58.2 acres of floorspace that the company will utilize for the manufacture of its products. The buildings completed recently cost $1,000,000 and those in the course of erection amount to $350,000. The company will have a total of sixty-six buildings when all plans for immediate construction are finished. Those r completed and under course of con tion include a traffic garage, 54.9 b 103 ft., two six-story additions to the stock room building, each 103 by 200 ft., a power house addition four stories high, 65 by 140 ft., two four-story additions, each 60 by 396 ft., a lumber storage shed 50 by 140 ft., a truck storage building, 36 by 272 ft., and a heat treating plant four stories high and 60 by 130 ft. There will be a total of 2,553,272 sq. ft. of floorspace when all structures in course of erection are completed, divided into four divisions: main division, 1,792,061 sq. ft., service division, 216,087 sq. ft., truck division, 346,292 sq. ft., and the forge and foundry division which serves both trucks and pleasure cars and will have 198,380 sq. ft.

5530 Major Machines

There are 5530 pieces of major machinery in the factory of which 550 were recently installed including the following among the more important:

Toledo press, cost $8,000, which has a pressure capacity of 250 tons and is used to stamp sheet metal into running boards, bonnet sides, fenders, etc., and which is almost as large as one side of the building it occupies.

A flywheel machine that performs all finishing operations on the raw flywheel casting in 11 min.

Two worm bevel gear wheels and worm bevel pinion cutters that cut to 0.001 in., and which cost $3,000 each.

A milling machine, cost $6,275, that mills the rough off the cylinder blocks

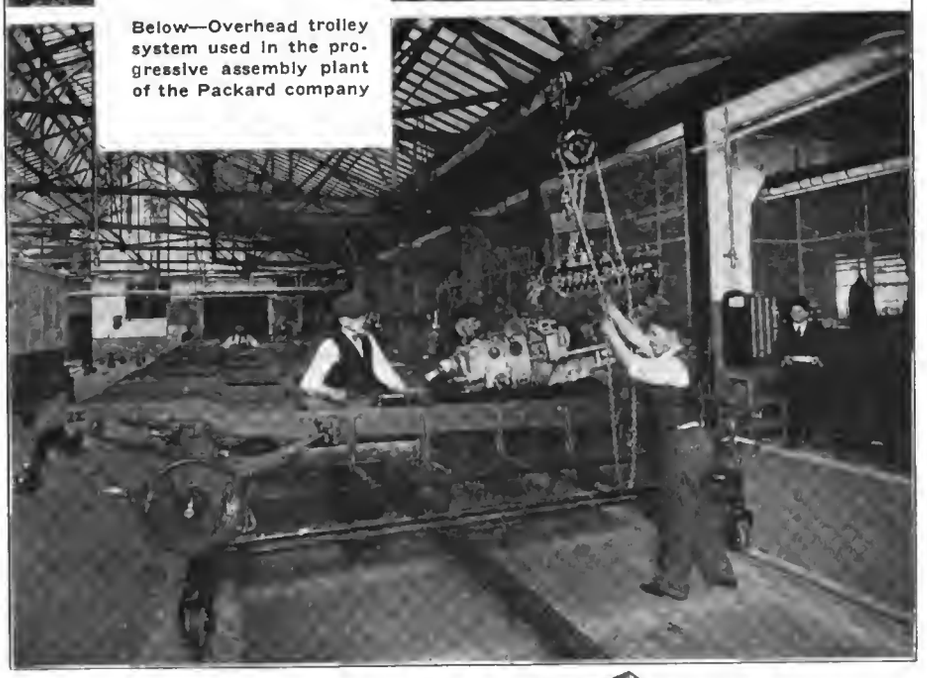
Above—Showing the constant building in which the Packard company is now engaged

Below—Overhead trolley system used in the progressive assembly plant of the Packard company



Two of the recent additions used for progressive assembly work

and reams it in consecutive operations in 6.7 min.

Two smaller milling machines of the same nature as the one above.

A cylinder boring machine that bores out rough cylinder blocks, and mills it by a progressive revolving operation.

Eight multiple drills costing $3,000 each and capable of drilling 156 different holes in the crankcase and cylinder blocks in 28 min.

One multiple drill that bores forty-seven holes in the transmission case in one operation.

Two hydraulic presses that force the rear axle housing onto the tube and have a pressure of 20 tons to the square inch. Each of these machines takes a floor-space 10 by 30 ft.

Two special Packard machines that dome the inside of cylinder blocks and which were designed, invented and built in the Packard factory.

Progressive Assembly

The plant operates upon the progressive assembly and manufacturing system based upon six divisions arranged as:

(*a*) Progressive machinery.
(*b*) Progressive stock conveying.
(*c*) Progressive chassis erection.
(*d*) Progressive motor assembly.
(*e*) Progressive enameling.
(*f*) Progressive final assembly.

The stock conveying mechanism was recently finished for the assembly of rear axles and transmissions at a cost of $35,000.

The final assembly is conducted in one of the new buildings that parallels the stockrooms and is so situated that the bins can be loaded with fifty car lots of various stocks at one time and the workers are never forced to move more than 7 ft. from the stock supply. Both floor and overhead trolley conveyors are in use. The bodies are lowered on to the chassis by means of the overhead system.

New ovens, 126 ft. long, have been installed in the enameling rooms and are capable of 400 to 500 deg. of heat. Two huge tanks holding 1860 gal. are utilized to clarify the enamel and a mechanical washing machine was recently added that contains 250 bbl. of water and is used to secure and cleanse all parts before they are enameled.

12,000 Employees

The company employs 12,000 men and plans to use 15,000 when the buildings now being erected are completed. It does much for its employees to uplift them in their homes, business and social life and has commenced several schools besides erecting a clubhouse and baseball ground.

The school includes courses for salesmen, truck manufacture and motor work, and also the teaching of English to foreigners.

Guaranty Securities Corp. To Finance Truck Sales

(*Continued from page* 789)

There are two charges, Charge A and Charge B. Charge A applies to all trucks below $1,500 and Charge B must be applied to all above $1,500. Charge B may be applied to those below $1,500. Charge B is the addition of a flat $30.50 to Charge A to cover collision insurance, and in case the service is such that collision is at all probable the dealer may insist upon the buyer paying Charge B where Charge A might otherwise prevail.

Above $1,500 the Charge B is 5 per cent of the delivered price.

These two charges are made because the collision risk is considered greater on the heavier trucks. Rather than base the charge on weights it was deemed more satisfactory to base the dividing line on price, the corporation believing that $1,500 is a good mark between heavy and lighter vehicles.

In case trucks are going into such a rush-and-hurry service as mail delivery, and if the price is below $1,500, the collision risk is greater, and in that case Charge B would apply below $1,500.

Charge A, as does Charge B, includes the usual fire and theft insurance and covers the cost of handling the deal. The insurance becomes effective as soon as the contract is signed and the truck delivered.

The dealer determines whether Charge A or B is to be made.

In case the dealer takes a car or truck in trade the allowance made must be included in the 25 per cent cash payment that he secures when the new truck is delivered. The Guaranty corporation will not finance the sale of used trucks.

If a buyer wishes he may pay more than 25 per cent down and may make the term of payment less than one year—but not more. Dealers are encouraged to get as much down as possible and as short a payment term as possible.

The interest on the notes and the Deferred Certificate must not exceed the prevailing legal rate. In most States this is 6 per cent, wherefore 6 per cent has been used in the table at the beginning of this story.

After the dealer has secured the 25 per cent cash payment he enters into a conditional sale contract with the buyer. This form is laid out in a very simple way. Under each blank space to be filled in is a small number. On the first page of the contract is told what these numbers mean, so that the dealer may always know just how to make out the contract. For instance, under one blank space it says "7." The first page of the contract says: "7, the amount of the note." So, where it says "7" the dealer writes in the amount of the note.

Handling the note is made simple. The note is attached to the first page of the contract. All the dealer has to do is fill in the blank space as explained by the numbers, there even being directions as to where the buyer's name shall go. It is difficult for a dealer to go wrong in filling out this contract and note.

Having the contract and note signed, the dealer forwards them to the Guaranty Securities Corp. and in a few days receives 90 per cent of the face of the note in cash. He then has 25 per cent of the whole and 90 per cent of the 75 per cent balance, which amounts to 92½ per cent of the whole price of the truck, including freight.

For the remaining 7½ per cent the dealer has to wait until the buyer makes the last payment, but this is represented by a Deferred Certificate, upon which he receives interest at the same rate the note itself carries.

The dealer has nothing whatever to do with making collections, and the buyer deals only with the securities corporation. Local banks are not involved.

One other little job the dealer has to do is have the buyer fill out a Purchaser's Statement. Statement A is used in case the buyer is worth more than $5,000 and Statement B if he is worth less.

Matters are still further simplified for the dealer by the attachment to the contracts, which are in duplicate, of a printed letter form. This is filled out by the dealer and mailed with the note and contract to the Guaranty corporation.

Advantages to the dealer are: He can

Extend his business without increasing his capital.

Secure sales where cash-buying might stand in the way.

Get all his cost and nearly all his profit at the time of sale.

The buyer:

Gets his truck at once and pays for it while he is using it.

Does not have to have credit handled through local bank.

Notes are held in trust, not hawked about.

THE DEALER'S PART.

1—Collects 25 per cent of $1,312 in cash, which includes the $67.50 that goes to the Guaranty Securities Corporation	$328.00
2—Sends to Guaranty Securities Corporation note for the balance of 75 per cent	984.00
3—Receives at once 90 per cent of face of note, deducting $67.50, which was received by dealer for Guaranty Securities Corporation's charge	818.10
4—Dealer has received in cash at once	$1,146.10
5—Receives Deferred Certificate for 10 per cent of $984, bearing interest at 6 per cent...$98.40	
6—When last payment is made he gets the $98.40	98.40
List price of truck plus freight	$1,244.50
7—Dealer also receives 6 per cent interest on the $98.40 Deferred Certificate	5.90
Dealer actually receives for truck	$1,250.40

THE BUYER'S PART.

1—Pays cash 25 per cent of $1,312	$328.00
2—Signs conditional sale contract and note for balance of $984.00	
3—Pays $82 monthly for 1 year	984.00
Delivered price of truck	$1,312.00
4—Also pays interest on the note	31.98
Buyer actually pays for truck	$1,343.98
Price of truck plus freight	1,244.50
Cost of accommodation	99.48
Cost of accommodation per month	8.29
" " " per week	1.91
" " " per day	.33

GUARANTY SECURITIES CORPORATION'S PART.

1—Accepts from dealer the buyer's note for	$984.00
2—Advances to dealer at once 90 per cent of $984 minus the $67.50 Guaranty charge	818.10
3—Collects $984 from buyer in 12 monthly payments.	
4—When last payment is collected pays dealer Deferred Certificate of $98.40, plus interest at 6 per cent.	104.30
5—Company realizes as follows:	
a—Guaranty charge $67.50	
b—Interest from buyer 31.98	
Total	$99.48

Guaranty Plan for Selling Trucks on Time

Illustrating by a truck listing at $1,200 and on which the freight is $44.50. The interest rate is assumed to be 6%. The plan is based upon the Delivered Price, which is arrived at as follows:

Factory list price, f.o.b., chassis and body	$1200.00
Freight	44.50
Price the dealer must get for himself	1244.50
Guaranty Securities Corporation's charge	67.50
CUSTOMER'S DELIVERED PRICE. What the buyer must pay	1312.00

CHARGE A

May apply up to $1,500 Job. Includes incidentals and usual fire and theft insurance for one full year.

CHARGE B

May apply up to $1,500 Job—Required on trucks selling for more than $1,500. Includes incidentals and usual fire, theft and collision insurance for one full year.

GUARANTY CHARGES

Engine Development

POWER plant improvement is a major development in the industry. Every demand made upon the car is reflected in the engine. The automobile-buying public has been educated to the point where the engine demands are in excess of what the nature of the fuel would suggest as being feasible, and the matter has developed itself into a contest between the possibilities of the fuel and of superdevelopment in the methods of vaporizing it and burning it.

The path for future progress is fairly clear. There is little doubt regarding the way in which design must travel if it is to continue to progress. Better vaporization of the heavier fuel, increased volumetric efficiency, or in a word, the increase of mean effective pressures by improvements in design which will tend to get the gas into the cylinder in a condition best suited for rapid combustion and with the least possible friction due to restrictions and bends in the ports.

Lighter reciprocating parts are a necessary development due to other improvements which have permitted higher speeds. With the power plants of a few years ago where the maximum piston speed was 1000 ft. per min. for passenger vehicles, it was not necessary to be so very careful regarding reciprocating weights and balanced crankshafts.

With many manufacturers recommending a piston speed of 2000 ft. per min. for passenger cars, these things become necessary. Furthermore, the gas speeds have increased, and it is necessary that ports be smoother, that the fuel be better vaporized (even though it is heavier), and that the volume of the cylinder is better filled at each stroke.

The small high-efficiency power plant is surely going to increase. To-day there are engines on the drafting boards which should be capable of maintaining 3000 r.p.m. steadily and without vibration of over-stressing of the parts. The high-speed engine provides the answer to the 4-to-50-mile-an-hour flexibility, and it is along these lines that the development of the next 2 years is likely to occur.

Detachable Heads

ENGINES with detachable heads are on the increase and have proved successful with very few exceptions. There are certain precautions to be observed in the design which when followed give a unit that is accessible and easily taken care of.

Where the detachable head has failed it is generally because insufficient water was carried into the head because of improper passages leading from the cylinder casting to the head casting. If these passages are arranged correctly there will be no difficulty in getting the water around the head.

It will be impossible to use anything but a good quality copper-asbestos gasket between the cylinder and the head. If a plain paper gasket is used there will be trouble as soon as a renewal is attempted and a leakage will occur. The copper-asbestos gasket is more expensive, but that expense is justified, and seems necessary.

The benefits to be gained from the removable head are many both from a manufacturing and maintenance standpoint: They are an aid to accurate cylinder grinding and are valuable in that they assist the manufacturer to maintain a very narrow limit of variation on combustion chamber size. To the user they are a great boon when it comes to cleaning out the cylinders, removing carbon or in grinding valves.

The Tractor Engine

ENGINES for tractors must be able to battle successfully with the dust cloud. There are two ways of doing it: First by keeping everything tightly closed so the dust cannot enter and second by making the parts of such materials that they are not damaged by dust. The designer of a tractor motor must do both.

The two important entry points for dust are the breather and the carbureter. A washing arrangement for the carbureter air will prevent the grit from entering. On the breather there is plenty of room for ingenuity to keep the dust out and each manufacturer has a pet method of his own.

In the way of materials, the parts must be hard so that the little diamond-like grains will not cut them, and furthermore, they must be large and stiff to withstand the racking stresses of a tractor.

Engines for 1917 a Culmination of Refinement

Few New Designs But Great Improvements in Detail Result in Higher Thermal and Mechanical Efficiencies—Longer Life and More Economical Manufacture Part of Year's Progress

Part I—The Trends in General

By J. Edward Schipper

THERMALLY, mechanically and economically, the American gasoline engine has received a great forward impulse during 1916. If all the progress made by our individual master builders could be concentrated into a single engine, that power plant would give back more power and useful work from a given quantity of fuel, more energy for a given size, travel farther on a gallon, be less expensive to manufacture, easier to maintain and have a longer life than the product of a year ago.

At this very moment we are in the midst of a period of engine development which makes almost certain the prediction that during the next 12 months a longer stride in the direction of perfection will be taken than the combined steps of the past decade. The latest products of our power plant specialists are capable of a performance as stock jobs that far surpasses the special engines of even 3 years back. And the most significant fact in connection with the development is that nowhere can be found a radical revision of design. What has been accomplished has been done by steady and patient digging into details.

Our engines for 1917 are more efficient thermally, principally because they are more efficient from a volumetric standpoint. The development of the high-speed engine has worked against the development of higher volumetric efficiencies and yet the improvements in detail of design have actually brought forth a net gain in that respect. It will be interesting to note, in going through this story of improvement, how minor changes in the valve action in some instances, the port design in others, and in some cases the rearrangement of very small details have added as much as 20 per cent more power to a power plant.

Mechanical Efficiency Increased

Mechanical efficiency has been increased largely through the carrying out of trends that were clearly expressed a year ago, and chief of these is the reduced weight of reciprocating parts. Next in order comes the balance of rotating masses, and third the better arrangement and individual design of the lubricating system insofar as the placing of the oil bath at points where it is most needed and in the proper quantity is concerned. Mechanical efficiency of an engine is the ratio of the brake to the indicated horsepower, expressed mathematically. It is a measure of the approach towards the ultimate in any given motor size, and when it is stated that the engine of 1917 has a better mechanical efficiency than its predecessor, it means that better performance is being secured from engines of equal displacement. Here again it will be highly interesting to note how the alterations in detail have brought about this important result.

Accessibility and Life

Coming to another broad highway of progress, that of longer life, it is found that the general methods for securing this have been in the reduction of stresses on parts through better design. Put in another way, it means higher factors of safety secured through better arrangement of parts, better materials, safer dimensions in a few instances and indirectly through a very important development in the way of accessibility. The two qualities of accessibility and life are bound very closely together.

The qualities demanded by the automobile buyer have forced this progress. A buyer of to-day demands a car that will have a speed range averaging from 4 to 50 m.p.h. on high gear. He demands a large power-to-weight ratio to give acceleration and hill-climbing ability and silence. Smoothness, economy and low price are among some of the other requirements that are made and insisted upon. To meet this demand with an engine that has for its working medium a fuel which is ever presenting greater difficulties in the way of vaporization, has taxed the ingenuity of the engineers as never before.

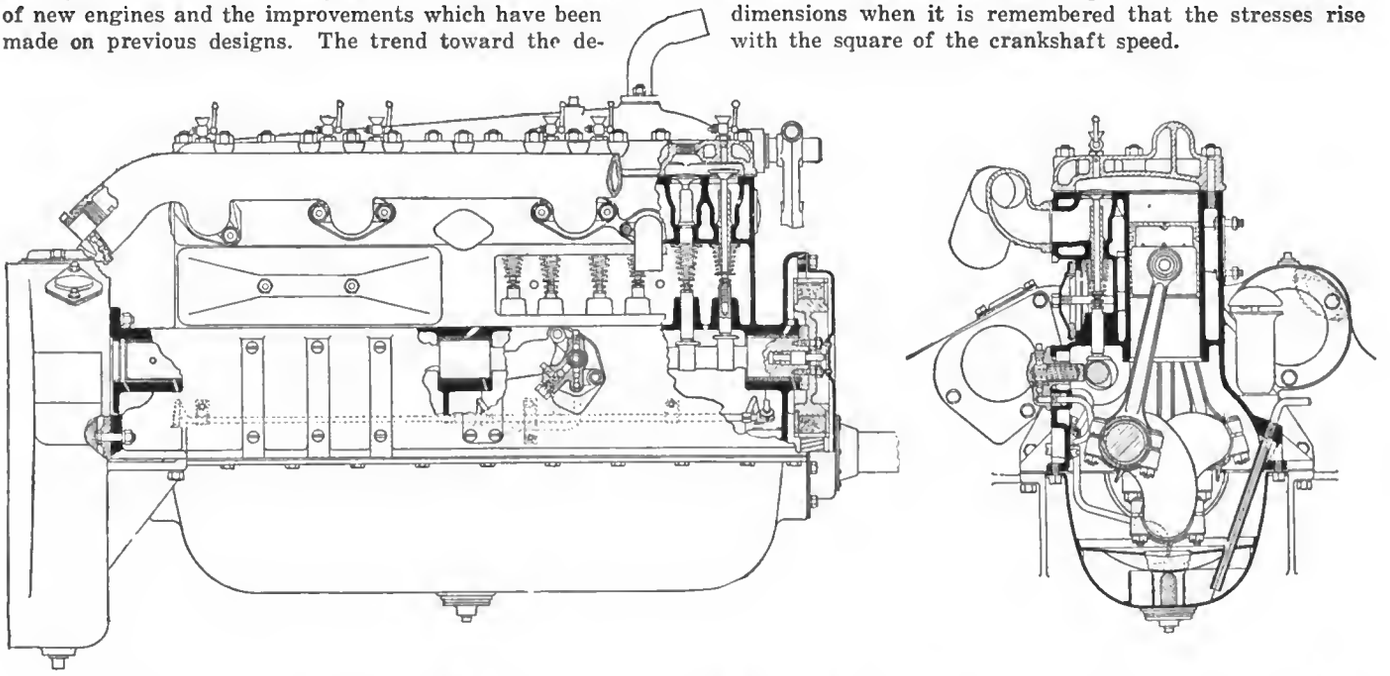
One of the greatest factors this year has been in the matter of material prices. Tungsten valves, aluminum pistons and cylinders, aluminum crankcases, alloy steel crankshafts and gears have been

particularly affected by the rises. One result is that no attempt has been made to go beyond experiments particularly in the direction of the aluminum motor, during this year.

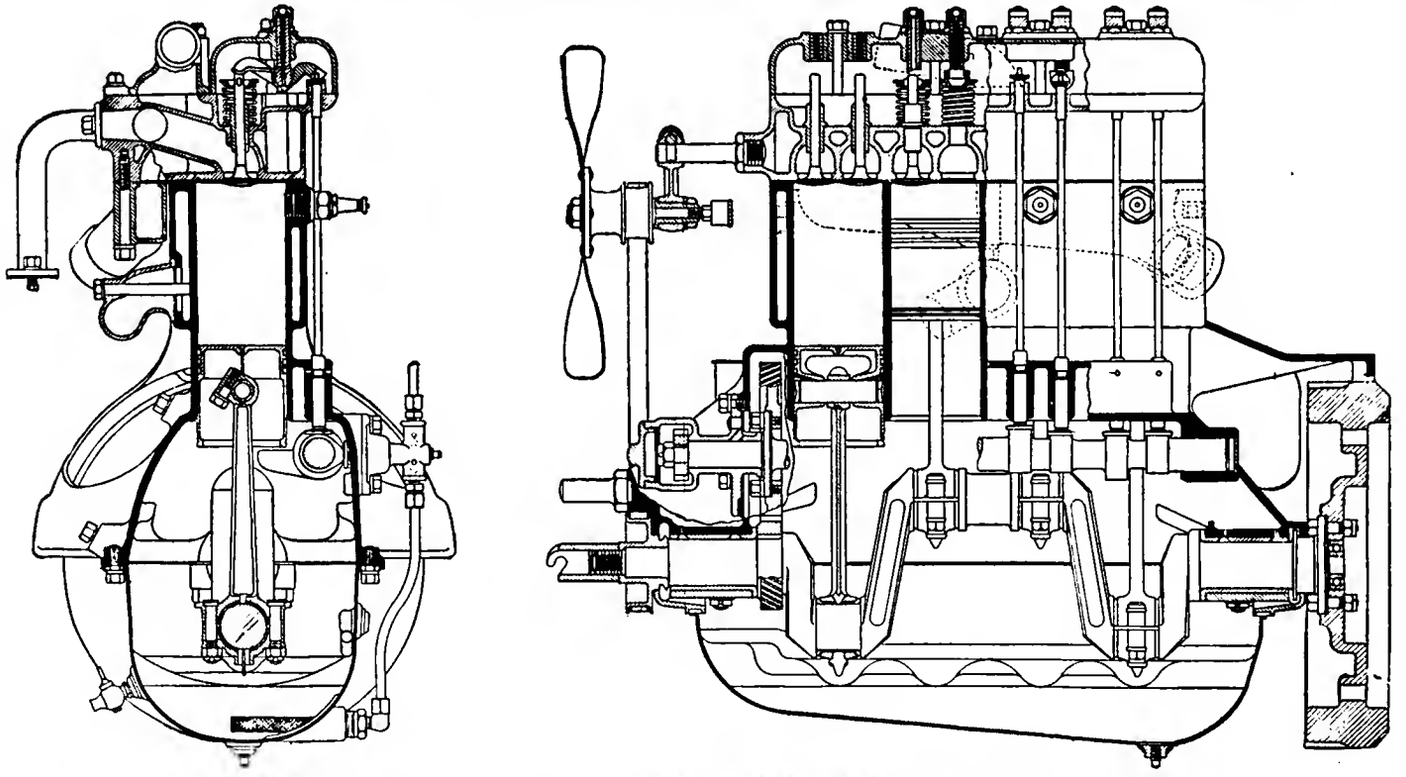
On the other hand, the improvement of machining and casting work has continued at about the same rate as in previous years and much of the credit belongs to these tool room designers who have enabled the motor manufacturer to produce economically and at a profit even in the face of the higher cost of materials.

In the general make-up of the engine, the trend toward the overhead valve seems to have struck its level, and there has been no falling off or increase during the year that is worthy of note. In fact the year is notable for the scarcity of new engines and the improvements which have been made on previous designs. The trend toward the detachable head continues. There has been one concern which has dropped the design, but others have added it so that the scale still shows a balance toward the detachable head.

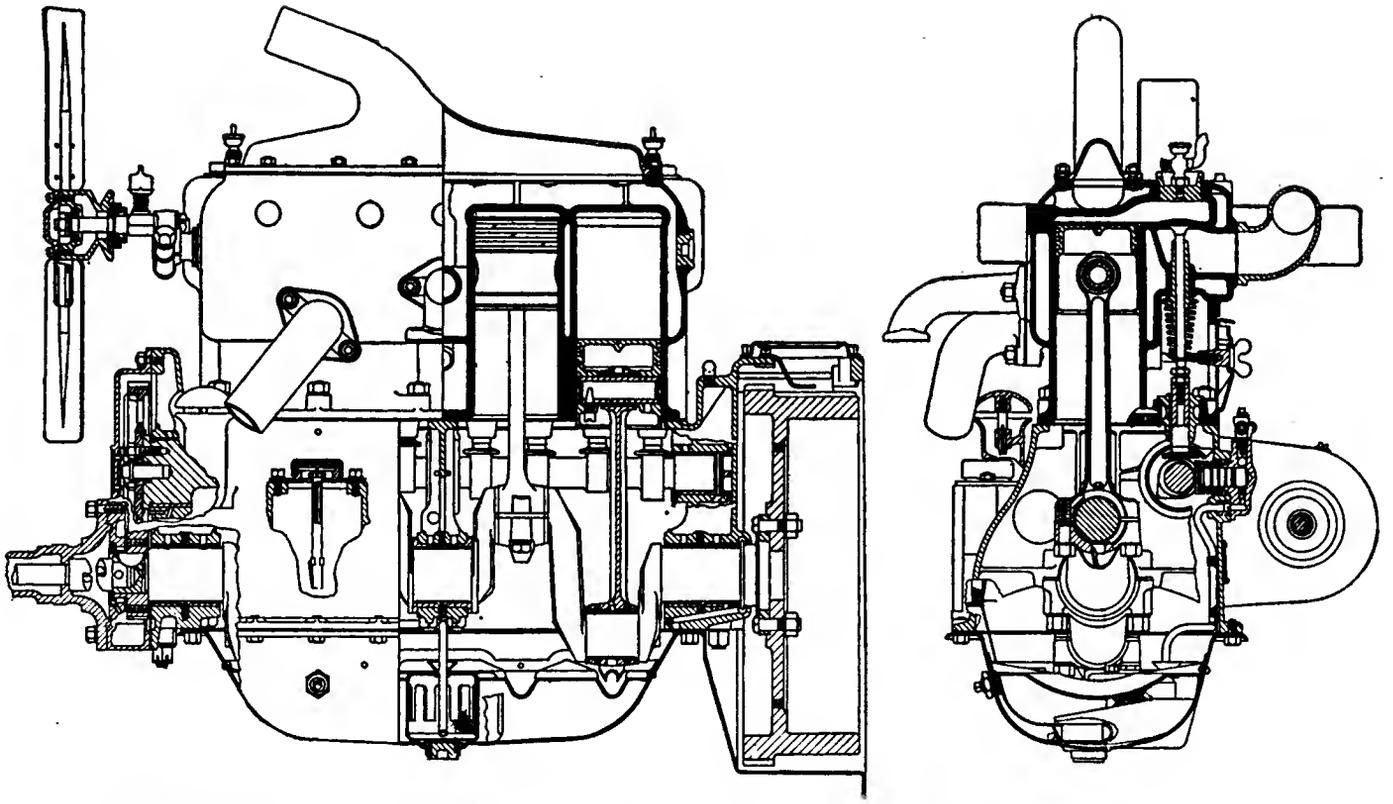
Crankshaft balance has been made more or less of a fad by the exploitation of some new designs through various sales mediums. As a matter of fact no new problems have been encountered by the engineer, beyond those which are natural with the higher speed of rotating and reciprocating parts. Piston speeds have been climbing up to the point where engine designers believe that the best practice for passenger car work is around 2000 ft. per minute piston speed. This is approaching quite close to 3000 r.p.m. and naturally the question of balance assumes proportions of considerable dimensions when it is remembered that the stresses rise with the square of the crankshaft speed.



L-head Continental engine with integrally-cast iron crankcase and detachable head. The end section at the right shows the moon-shaped throws on the crankshaft for balancing purposes. Crankshaft balance has received marked attention this season



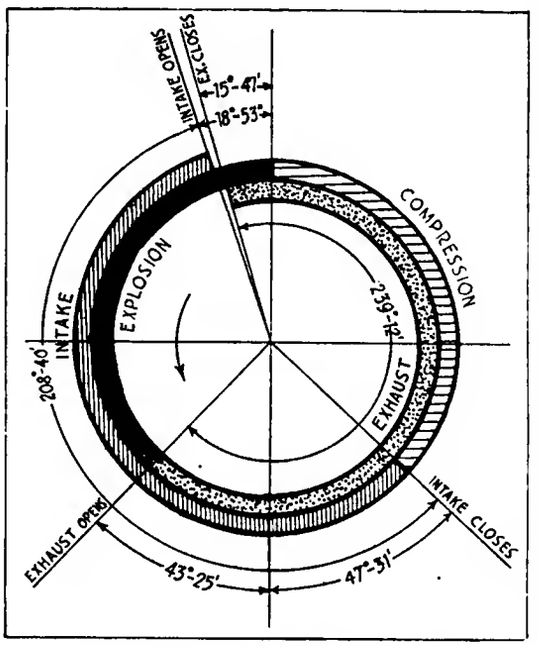
Sterling four-cylinder valve-in-head design for light passenger cars. It has a detachable cylinder head with the spark plugs in the side and the fan direct driven from the crankshaft acting as a vibration damper



Longitudinal and transverse sections through a typical Continental four-cylinder unit which can be successfully applied to trucks. The cylinders are cast in a single block, but the crankcase and oilpan are separate

The curved-cheek crankshaft is in the majority and instances of elaborate systems of counterweighting are practically unknown among the engine specialists. Perhaps the most interesting case of counterweighting is in an engine developed for gasoline-electric purposes by the Milwaukee Machine Tool Co., in which the counterweights are carried practically into the plane of rotation of the crank. The weights are brought as closely as possible to this vertical transverse plane while maintaining a pathway for the connecting-rod. This is a very small displacement engine, four-cylinder 2½ by 3½ in. designed to run continuously at close to 3000 r.p.m. and all parts are designed for such conditions.

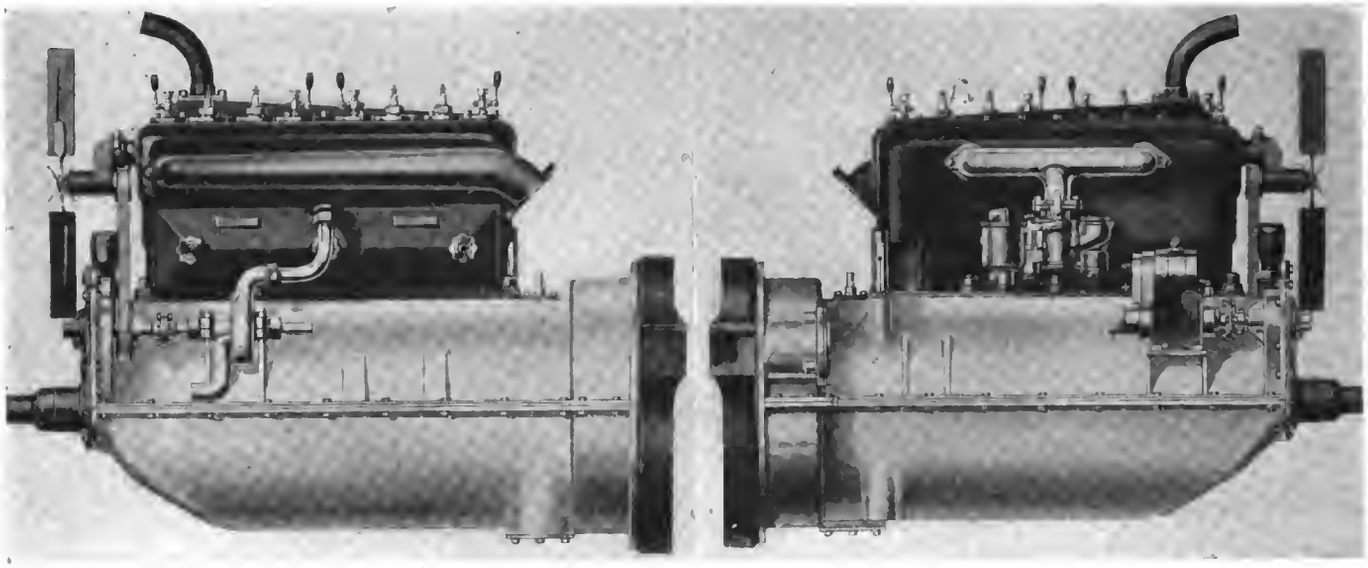
Another high-spot in gasoline engine development is in the provisions made to aid in the vaporization of the fuel. The day is past when the engine builder puts the entire question up to the carbureter maker. Almost every manufacturer of engines has devised some method of preheating the charge, and this in the face of the struggle for higher volumetric efficiencies. Yet it is a matter of necessity now. The day has arrived when the gasoline engine really can burn kerosene, and not a few of them are doing it. The tractor engine is the connecting link where kerosene and gasoline are both being used, and the cored-in intake manifold or the unit intake and exhaust manifold have become very prominent this year. The Waukesha motors have a very nicely worked-out double manifold and the Golden, Belknap and Swartz engine also has a new development in this respect. The Falls intake manifold is now incorporated in the removable head of the engine. These are good examples of what everyone is doing or has done on the newest models.



Valve-timing diagram of model 20 Sterling engine, looking at the front of the flywheel

Before going into the details of motor improvement it should be remarked that power plants are not, taking them as a grand average, lighter than last year because the use of aluminum has dropped off in crankcase work to some extent. They are more powerful for their weight, however, and this is really what counts as long as the weight is not excessive. Individual parts of the engine which promote efficiency through being light have been reduced in weight.

Aluminum pistons are still in the balance. Personal talks with practically every engineer in the motor manufacturing business still give the general impression that they have neither become accepted nor condemned for general practice. It is not so much a matter of price, although in the opinion of one engineer it costs $6 more per motor to use the aluminum with present prices. A year ago though, it seemed as if the aluminum piston would become the standard in all motors within a year. At the present time there is no doubt but that the opinion of the majority of the engineers is that the real lightweight piston has not as yet been developed. On the other hand, it does not lack its firm supporters, so the matter is still on the fence with experimenting actively being carried on all over the country. One interesting fact is worthy of comment and that is, the aluminum piston has found greater favor among the automobile engineers than among the motor manufacturers who build for the trade. Where the aluminum piston has fallen



Both sides of the Wisconsin 4 by 6-in. power plant. This is a four-cylinder unit which is capable of handling large sized trucks. It has considerable flexibility, its stroke-to-bore ratio being 1.5

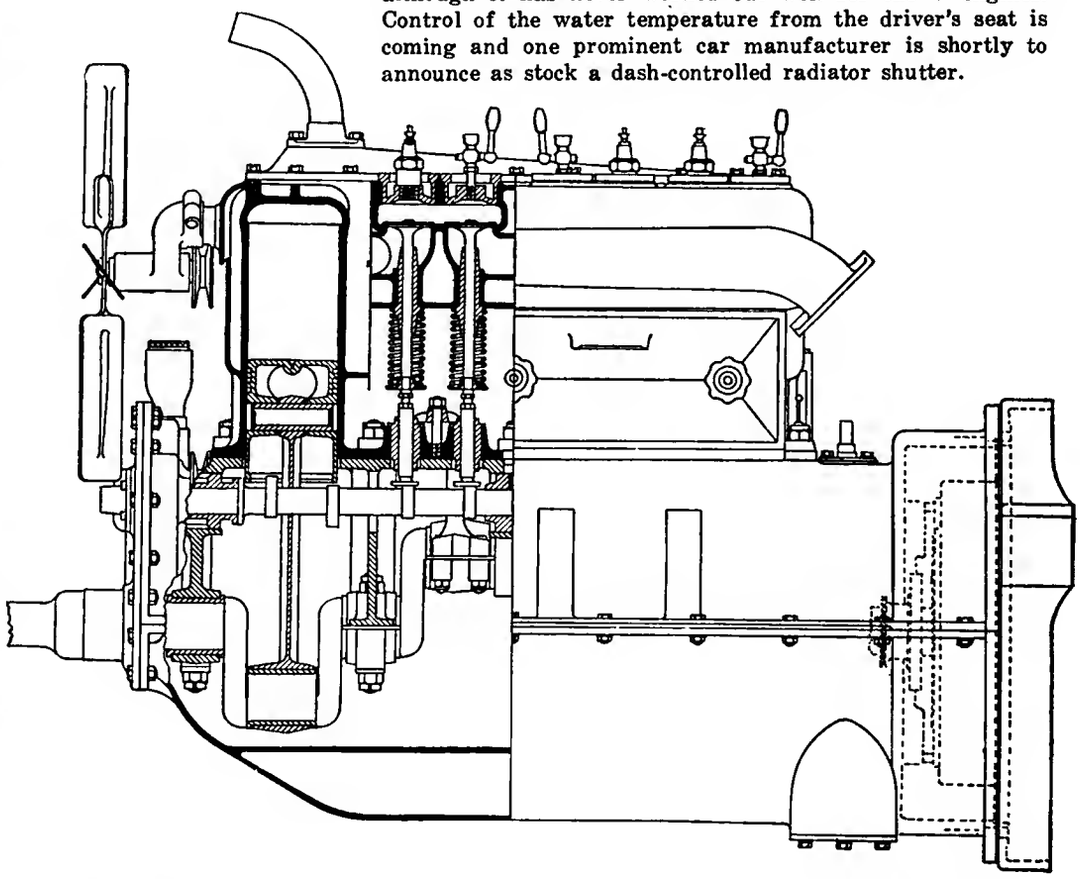
down, particularly in one instance where several cars were called in and changed over to iron pistons, it is because the pistons were made too short and secondly because the workmanship necessary to keep the clearances accurate could not be secured commercially in that particular installation.

The Eight and Twelve

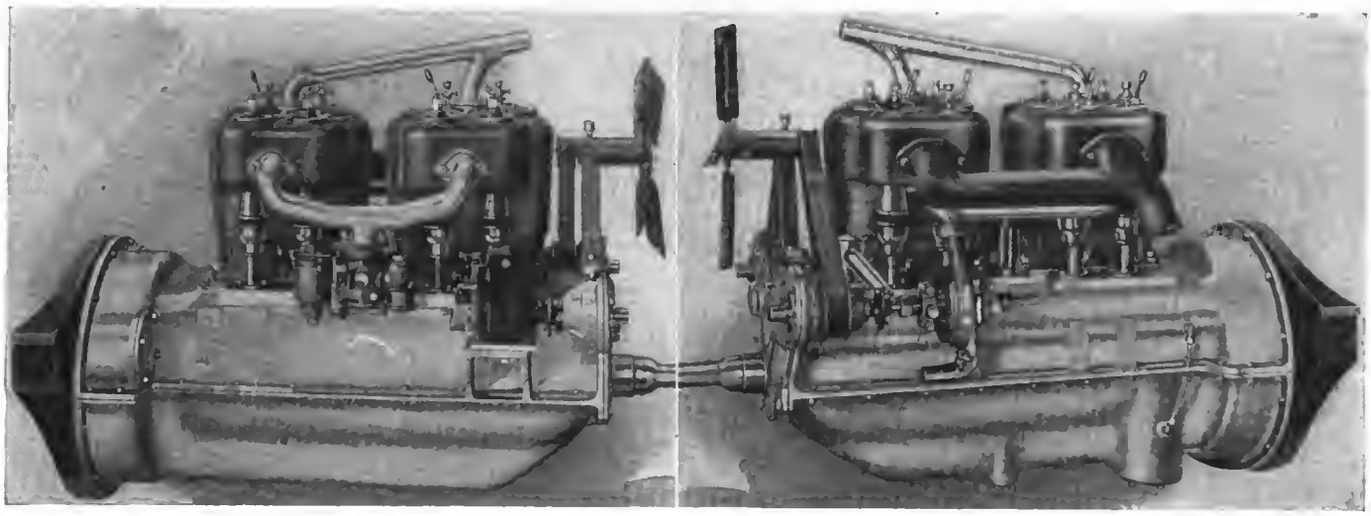
The V-engine cannot be overlooked in touching on the big points in engine practice. All doubt seems to have passed regarding its fitness. It is a question of cost versus performance. The question that each engineer must ask himself in deciding upon the building of a V-motor is whether he can get the same performance from an eight that he can from the six at the same price. The answer is both no and yes, because some have discarded the V, because they have felt that the six gives the better performance-cost answer, while with others it has been the other way around. Examples can be given on both sides so they mutually offset each other and show the point to be one that is open for debate, and since debate is stimulating and is really the key to progress, the V engine, besides having proved its fitness for the work, now stands as a champion of one type of design as opposed to the straight line variety. The shorter, stiffer shafts in the V are offset with the maintenance questions and altogether the question has various ramifications which are carried down to the limits of personal choice. During the year we have had practical demonstrations which have shown both types satisfactory.

Oiling has not changed greatly except that there is a tendency to keep the valve drive submerged so that it cannot become noisy. The details of this will be considered separately but in taking up the main trends it may be stated that oiling by circulating combination pressure and splash is typical. The oil pressure has gone up along with the speeds and now it is not uncommon to send the oil to the rubbing surfaces under a pressure of 40 lb. per square inch.

Cooling favors the pump-circulation among the motor builders. The proportion is about 66 per cent by pump and 34 per cent by thermo-syphon. The latter type of feed has been gaining for the past 3 years among the smaller engines although it has never worked out well for the V engines. Control of the water temperature from the driver's seat is coming and one prominent car manufacturer is shortly to announce as stock a dash-controlled radiator shutter.



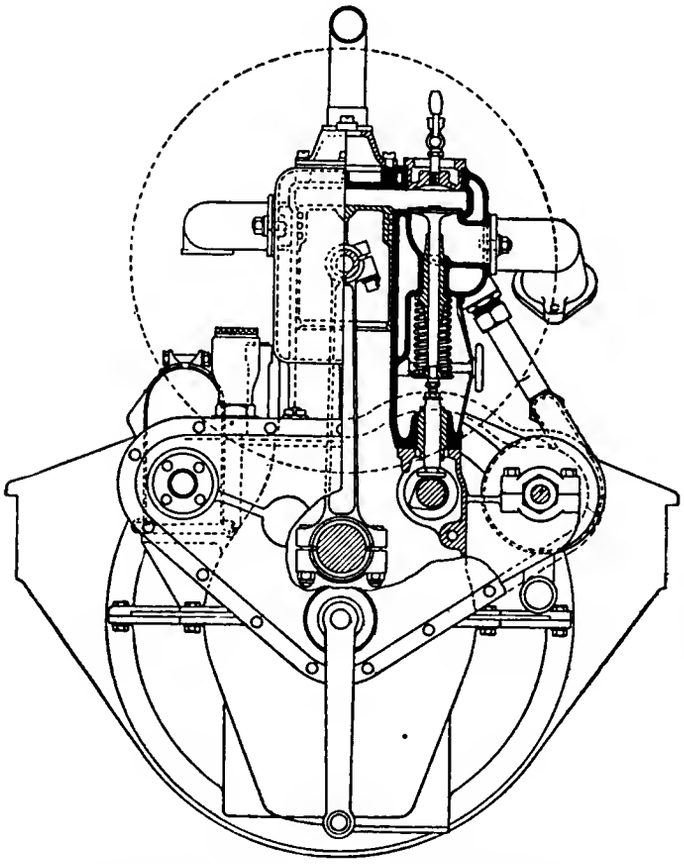
Wisconsin four-cylinder 4 by 6-in. engine which is used extensively for commercial vehicles



Wisconsin T-head engine which is known for its hard-pulling qualities. This model is a development extending over several years and has a bore and stroke of 4¾ by 5½

Part II—Mechanical and Thermal Efficiency Increased

Reduced Friction in Gas Ports, Higher Compressions and Greater Mean Effective Pressure Responsible—Maximum Piston Speeds Vary Through Wide Range



Transverse section through the Wisconsin 4 by 6 in. truck motor

THERMAL efficiency is a measure of the power secured from a given quantity of fuel. Mechanical efficiency is a measure of the power secured from a given size of engine. The two are closely related but still are independent. In increasing each of these factors, the use of a number of detailed improvements has been made which has had a marked effect on engines as a whole.

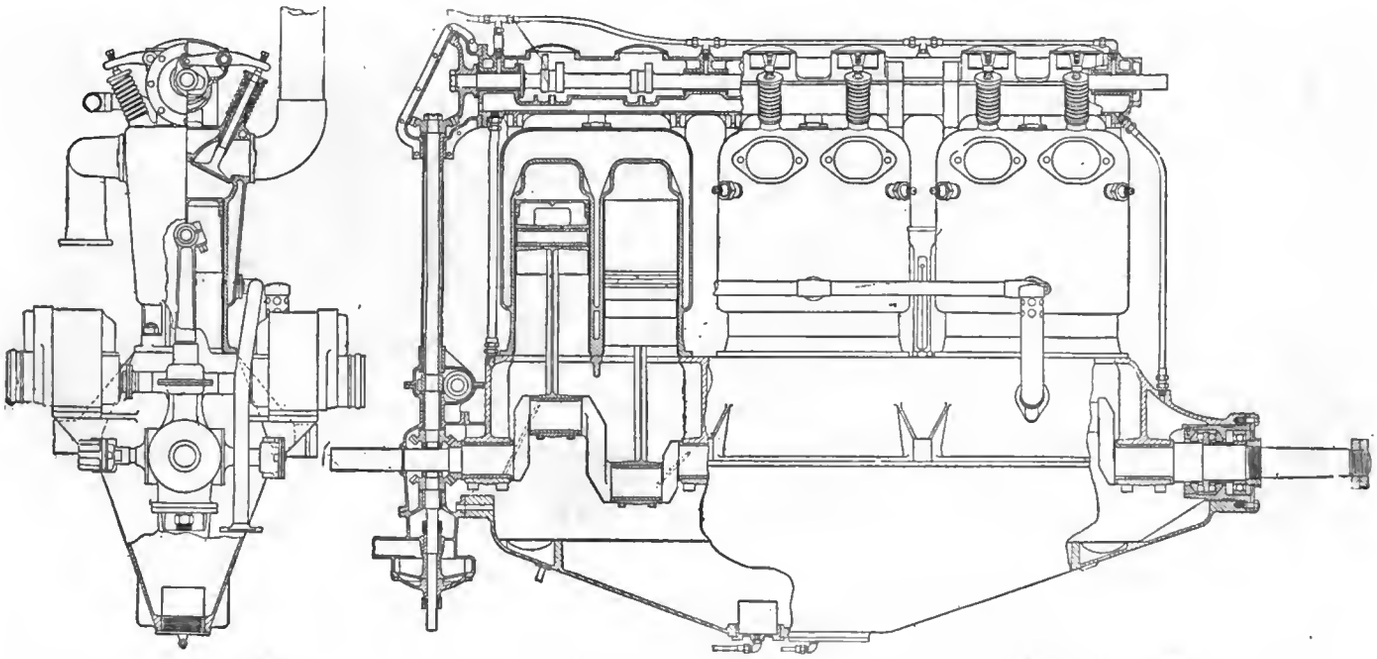
No other factor has had such attention this year as the increase in volumetric efficiency. This relationship between the volume of gas drawn into the cylinder and the volume of displacement is highly important because it is a direct measure of the relationship between the volume used and the volume wasted in an engine.

A number of factors have worked against the betterment of the volumetric efficiency, the two greatest of these being the higher speeds at which engines are operated and the second is the necessity for heating the heavier grade of fuel which is now being sold. The higher speeds have forced the engine builder to keep increasing the size of the valves year by year until in 1915 the limit was reached. It has been impossible to go any higher and consequently there has been very little alteration in this respect.

It has been discovered, though, that all the restriction of gas flow has not been in the valve but in the approach to the valve, and consequently there has been a universal house-cleaning of intake passages. The Sterling company has even given this volumetric efficiency matter such close attention that its engines have larger intake than exhaust valves.

Integral Manifolds

The use of the cored-in manifold has eliminated some of the bends in the passages, and has permitted of the direct connection between the carbureter and cylinder block. This trend is of about 4 years standing and is still on the increase.



Wisconsin six-cylinder aviation engine which has a valve action quite similar to that used on the Stutz racing cars. The camshaft is carried overhead

No notable change has been made by any of the companies in valve timing. In the overhead valve design there has been one tendency which has worked out very well and that is in the use of the offset rocker arm. In place of having the rocker with the fulcrum at the center it is off center so that the lift of the valve is magnified. The ratio then, instead of being 1 to 1, as it has been in practically every installation up to the last year, is now on a great many 1 to 2 or 3 to 5. The Falls Motor Co., which specializes on a valve-in-head design, has not adopted this practice on the ground that it would complicate replacements which would more than offset any gain.

The advantages claimed for the offset construction is that it eliminates a certain amount of inertia, owing to the smaller travel of the valve parts. This gives the effect of silencing the drive to some extent and further permits the follower to ride the cam better because of the lesser rise on the cam face. Besides this the leverage of the valve spring on the rocker arm, being greater, the spring can be reduced in tension, thereby compensating for the difference in the linkage.

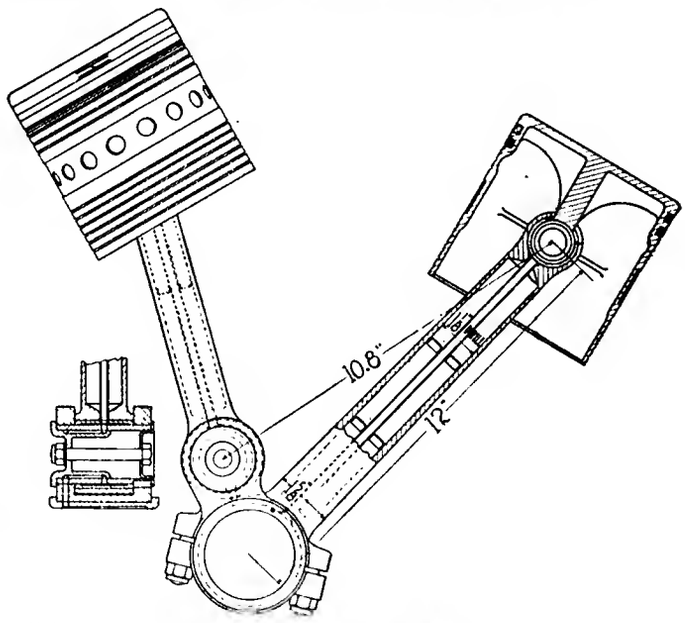
Another feature of the differential rocker is that it allows of a longer dwell of the valve, due to the quicker lift. This certainly reflects in the direction of higher volumetric efficiency as the time of maximum opening of the valve is increased and therefore a longer period is allowed for the gases to make their way into the cylinders.

Compressions are higher than they were a year ago. They vary to such an extent that it is impossible to draw a general trend. In truck motors the combustion space is quite often around 35 per cent of the piston displacement, while in motors like the Continental little six, which is a high-speed passenger car type, this percentage is about 30 or about 85 lb. absolute. The little Falls overhead job with a piston displacement of 180 in. for its six-cylinders has a compression space of 26.5 per cent of the displacement, which would give a compression average of over 90 lb. absolute.

Higher Mechanical Efficiency

The reduction in the size of the combustion space and the reduction of friction in the intake passages has more than offset the expansion of the charge due to preheating. The latter has been necessitated by the lower grade fuel, but does not seem to affect the power of the engine. Possibly combustion is more complete with the preheated and gasified charge. On a small engine being developed at the Milwaukee Machine Co. plant a novel scheme is being tried in shaping the passage below the valve in venturi fashion so that there is no break in direction of flow at the valve, but instead it gets the continuous flow effect imparted by the venturi. The throat of the venturi is just below the valve opening.

The increase in mechanical efficiency is largely wrapped up in the same matters as thermal efficiency. The higher compression has resulted in higher mean effective pressures, which in turn means a greater horsepower output from a given displacement. In the reduction of vibration due to the mechanical refinements, particularly in the crankshaft and reciprocating weights, there lies another one of the reasons for the increase in mechanical efficiency. Lower bearing friction will tend to bring this up, but it is to be doubted if this is being secured owing to the higher speeds and larger diameter shafts which have carried the linear bearing speeds close to the limit. When these rise over 1000 ft. per minute they are getting close to the limit for standard cars.



Pistons and connecting-rods of twelve-cylinder Wisconsin aviation engine

Part III—Refinements in Structure and Manufacture

Part-by-Part Study of Motors Shows That Every Detail Has Been Carefully Refined During the Year

TAKING the engine part by part, it will be discovered that there is some sort of refinement in every detail. This may be in the line of economical manufacture, lighter weight or in some other direction, but there is no part of the engine which has been left untouched. In some parts the line of deviation between passenger and commercial or tractor practice becomes highly marked. In others it has been possible to cut the cost of manufacture while at the same time the efficiency of the resulting engine may actually have been increased.

Gray iron, or what is known as 15 per cent semi-steel, is the king of metals for cylinder use. The aluminum cylinder has not gained this year and will not until aluminum drops from its present price level. In manufacture the ground cylinder is favored over the reamed-in small bores, while above 3 in. there is a leaning toward the reamed finish. One or two manufacturers believe the best results are obtained by rolling. Taking engine manufacture as a whole, it may be said that reaming and grinding are about equally divided. The consensus of opinion on this subject is that the reamed finish is excellent for wearing into a finish fit, while it is easier to grind the surface of the cylinder commercially, within the desired limits.

The desire for perfect balance has made the manufacture of equal combustion chamber volumes imperative. One of the Le Roi engines intended for high speed work is checked so that all combustion chambers must be accurate within 3 c.c. for volume. If desired that explosion pressures be equal on all pistons this must be done.

Another important feature in cylinder design is the question of how low the jackets should be carried. There has been a tendency all along the line to increase the water space, and jackets are universally larger. On the latest Falls motor, the waterjackets have been extended clear down to the crankcase line. In detachable head jobs, the passages for water from the main cylinder casting to the head have to be watched particularly. The Golden, Belknap and Swartz company has discontinued the detachable head because of a desire to secure better cooling in the upper part of the combustion space. This is the only instance, however, of where a detachable head has been dropped and the trend may be said to be in the opposite direction. A copper-asbestos gasket is necessary between the head and the cylinder, and any attempt to use a simple paper gasket at this point will be sure to end in failure as soon as a replacement is attempted.

No change in piston material can

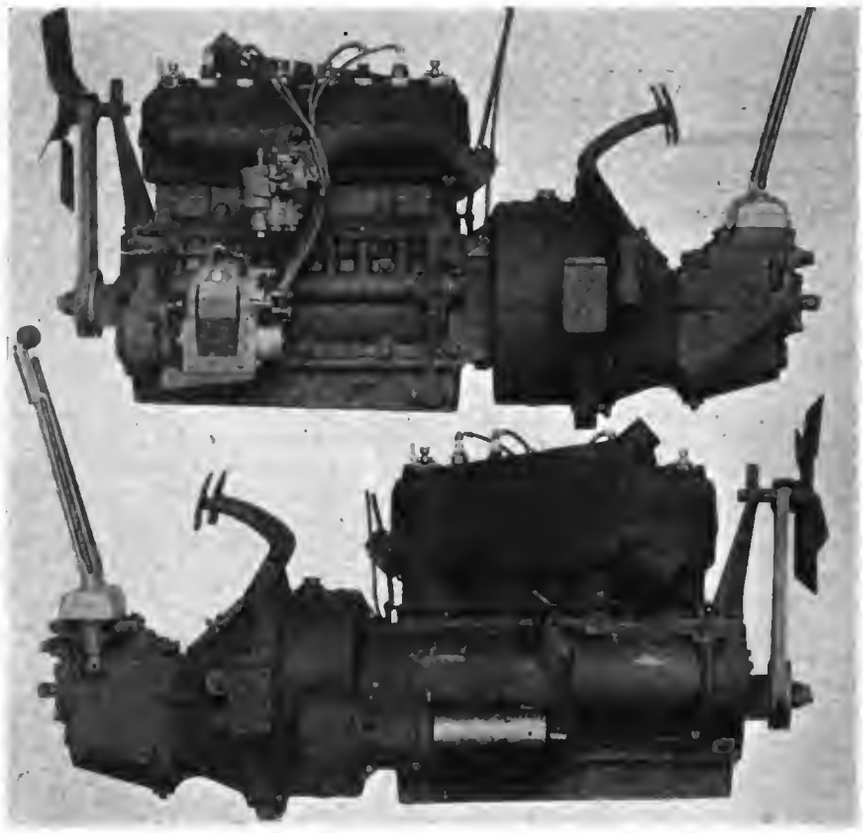
Golden, Belknap & Swartz unit power plant. This model is a 3¾ by 4¼ unit. Note carbureter mounting and diagonally-inclined intake manifold. Clutch and gearset details are shown at the right. End view of the engine appears above

be noted during the year, except possibly a slight backward movement toward iron where aluminum was tried a year ago. As stated, though, the aluminum question has not been settled yet. Gray iron, the same as used for the cylinders, remains far in the ascendancy.

Three rings, all above the piston pin, are practically standard, although one manufacturer, the Falls company, has changed to two rings and will place one of the patent leak-preventers in the top of each unit. For very high speeds two rings are enough, for the lower speeds it requires three eccentric rings to do the work.

Clearances on passenger car pistons have not changed during the year. On tractor work where the engine operates in a cloud of dust that cannot be altogether excluded, the larger clearances have been found necessary. On the Waukesha tractor motor, for example, with the 4¾-in. bore there is a piston clearance at the top of 0.018 in., which is more than double that of the corresponding passenger car engine with iron pistons.

Although cast iron remains as the chief piston metal, pistons have been made very much lighter all along the line. The skirts are thinner and the piston pin boss is not taking so much metal. The pistons are being carefully lapped to the cylinders by many, and in the Continental factory there is an interesting special machine which laps the cylinder by means of a dummy piston. On the little high-speed Le Roi engine the piston skirt is drilled all over with large holes for lightness.



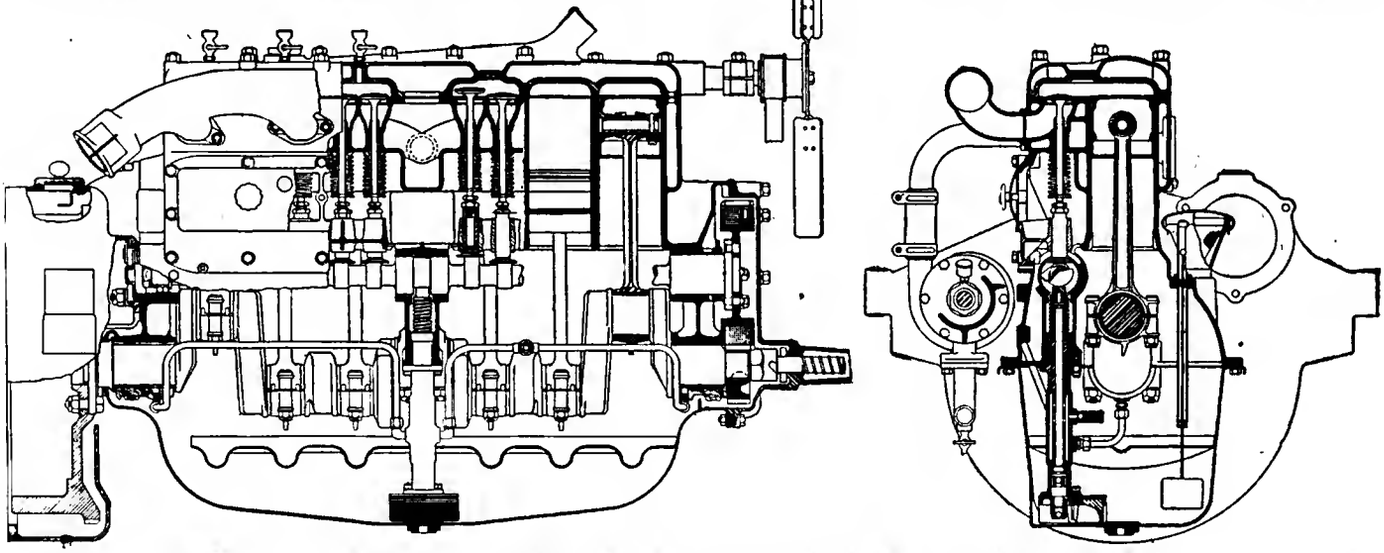
Golden, Belknap & Swartz unit power plant with L-head cylinders for small vehicles

On the Falls motor the piston pin has been lowered slightly and the difference has been taken off the connecting-rod length. A little piston kink that is used by some with good results is to taper off the top of the piston so that the oil instead of gathering on the head of the piston will gather in the space around the outside diameter, thus tending to feed itself between the piston and the wall.

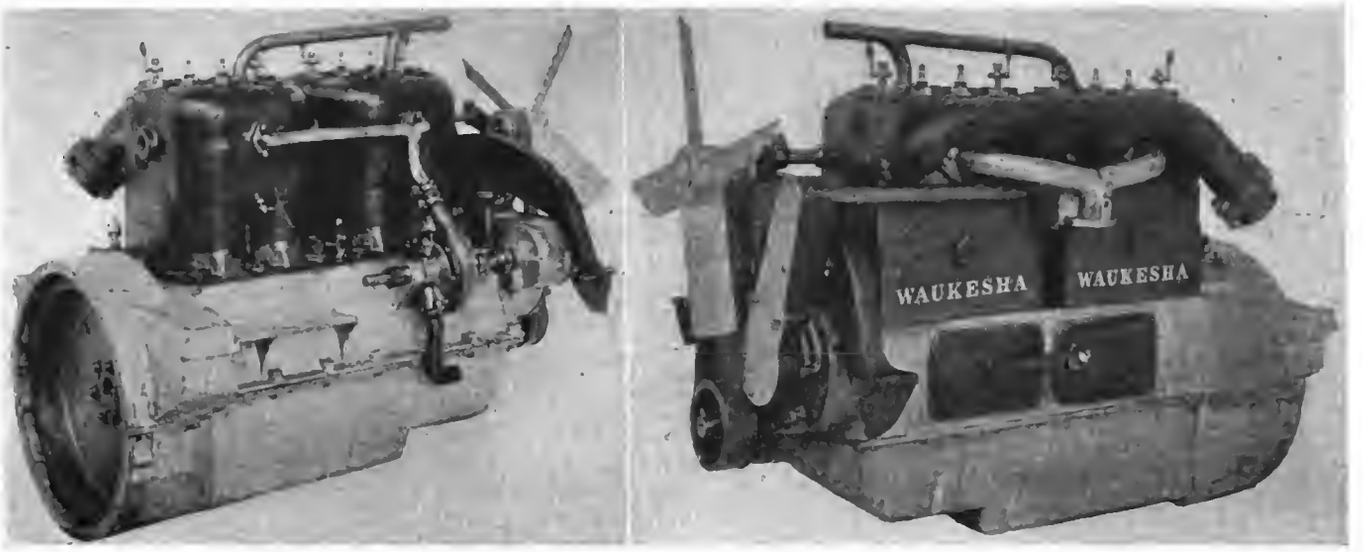
On all motors it is a desirable thing to be able to remove the pistons by pulling them out through the bottom past the crankshaft. This saves taking down the entire motor to replace a piston ring, for example, and is especially demanded for truck and tractor work, where time is invaluable. The majority of motors are being designed in this way, and no doubt others will rapidly fall into line. A slight difference in tractor practice, as compared with passenger cars, is that it is generally thought desirable to put the upper rod bearing in the piston boss with a solid connection to the rod. This is on account of a gain in bearing area. This practice is not universal, however.

Connecting-Rods

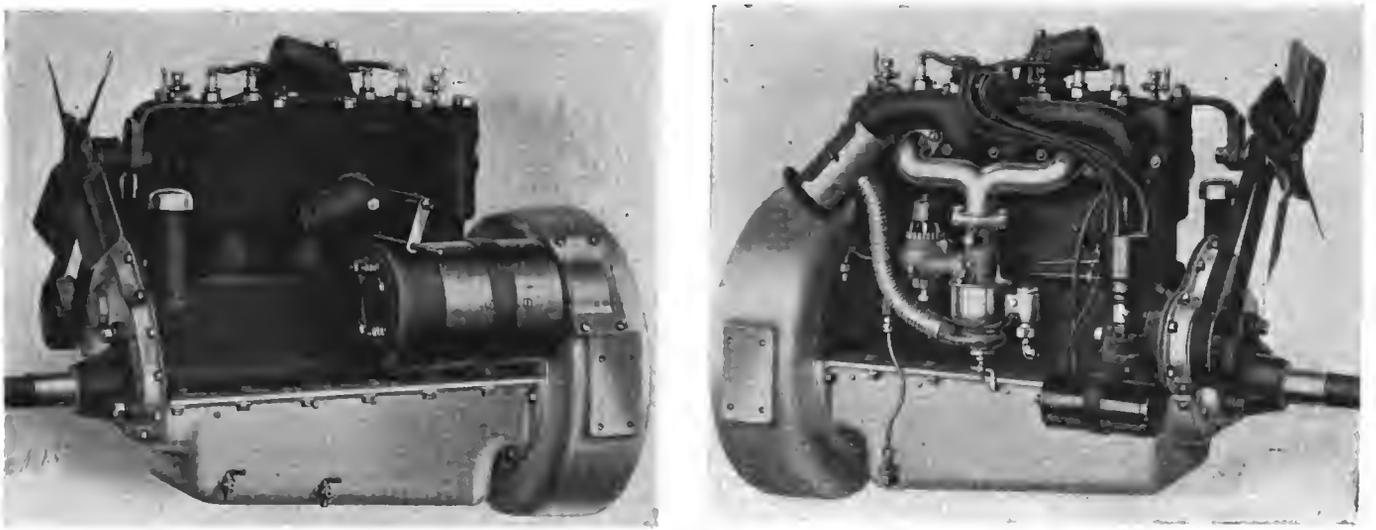
Little change will be found in rod practice. The straight I-beam is used almost universally and the material most employed is carbon steel, drop-forged and heat-treated. The tubular rod has not gained during the year, although in aeronautical practice it is coming in very strongly. The Wis-



Rutenber model 25, which has a bore of 3⅛ and a stroke of 5 in. This model has been improved by the use of a stiffer crankshaft and is larger in bore than its predecessor, giving altogether a more powerful and efficient design



Both sides of a Waukesha engine which is used extensively on tractors. Note how carefully all the moving parts are inclosed to guard against the abrasive action of the gritty dust in which tractors are generally compelled to work



Both sides of the 3⅛ by 4½-in. four-cylinder Le Roi engine, which is designed for light commercial or passenger car work. Note mounting of electrical units and arrangement of manifolds

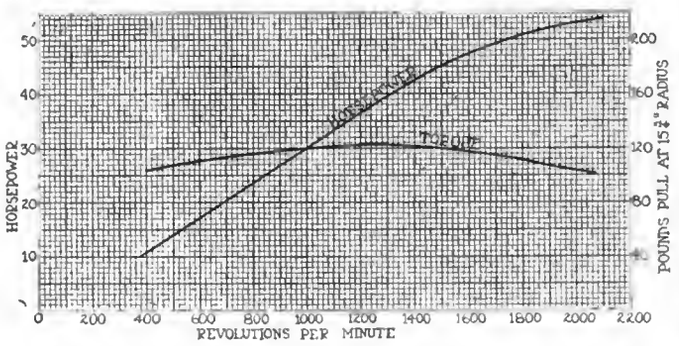
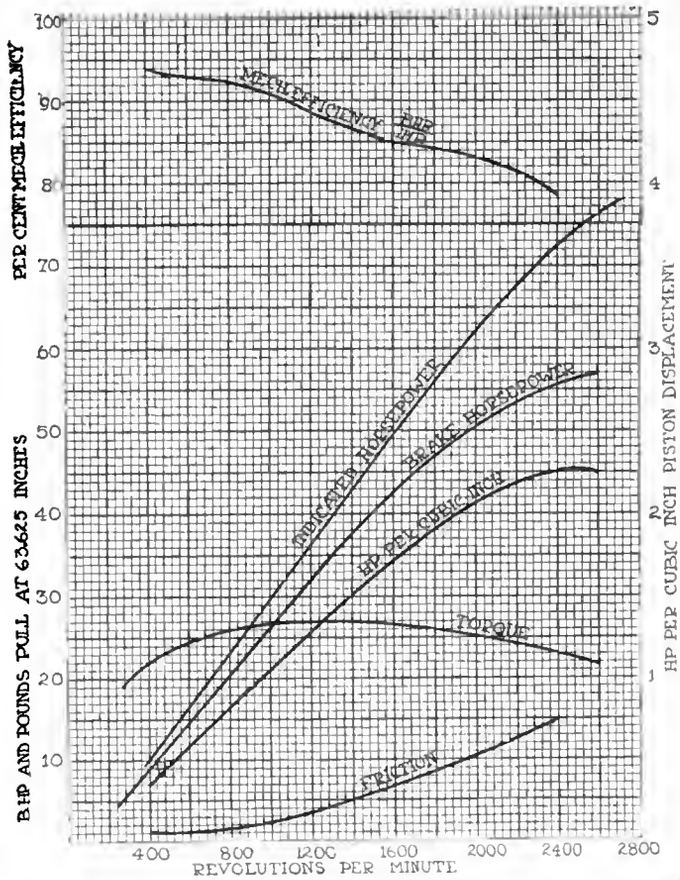
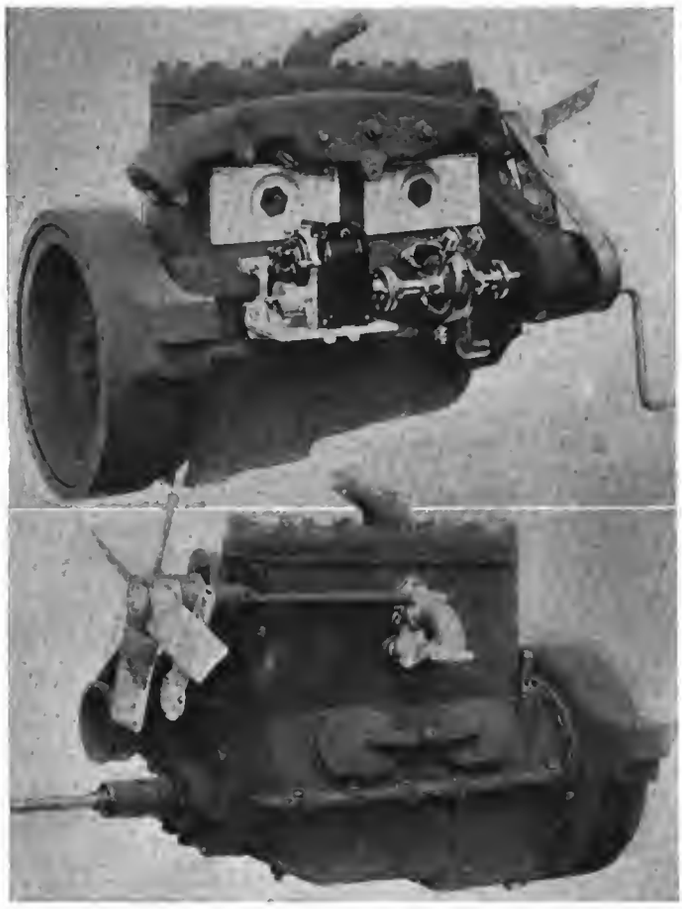
Lycoming four, for medium duty work on commercial vehicles. The generous size of the gas ports and the water passages surrounding the valves is indicative of present trends in this direction



Horsepower and torque curves of 3½ by 5⅛-in., six-cylinder Buda motor fitted with 1¼-in. carbureter



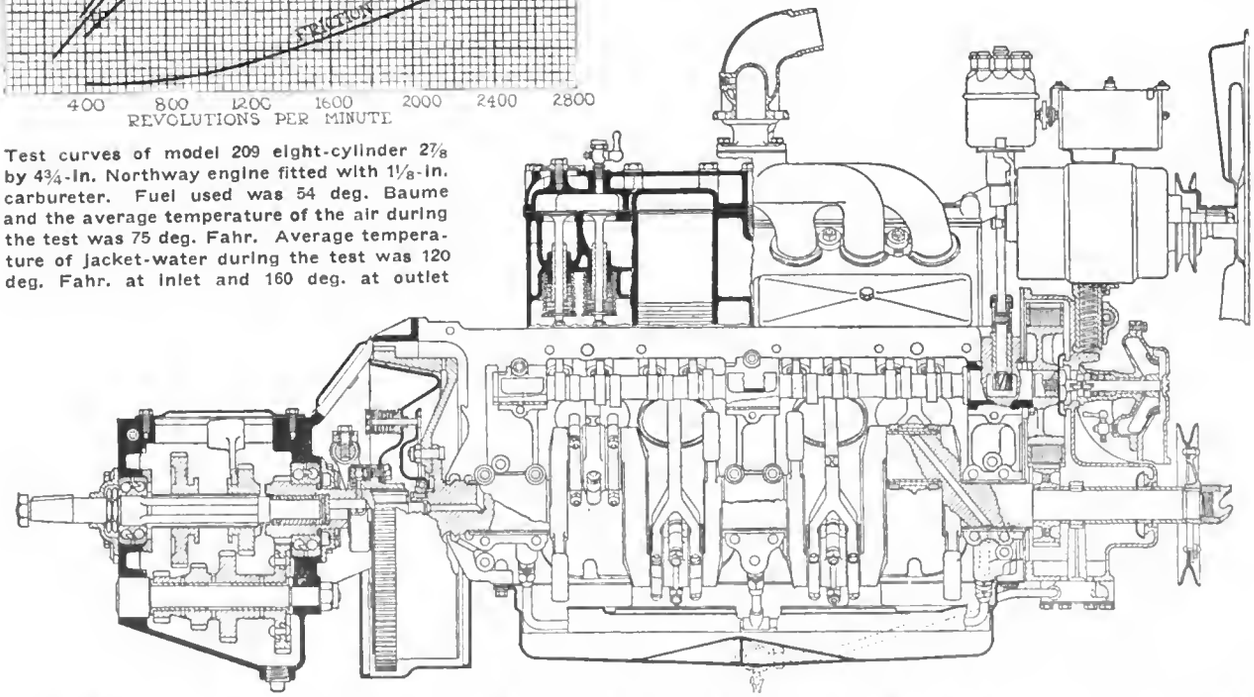
Test curves of model 209 eight-cylinder 2⅞ by 4¾-in. Northway engine fitted with 1⅛-in. carbureter. Fuel used was 54 deg. Baume and the average temperature of the air during the test was 75 deg. Fahr. Average temperature of jacket-water during the test was 120 deg. Fahr. at inlet and 160 deg. at outlet



Waukesha motor intended for tractor service. Combined intake and exhaust manifold aids vaporization of kerosene

consin aeronautical motor has the rods made from solid billet steel. Needless to say this practice is far beyond automobile work except for special cases such as racing.

The shorter rod of the Falls motor, due to the dropping of the piston pin, is the only example where rod lengths have been changed.



Northway eight. Note the single three-bearing, sixteen-cam shaft and the use of the forked rods. Both of these points have been much discussed in eight-cylinder practice and this engine is typical of this class of motor

Where manufacturers take the pains to mill off the flash from the drop forged rod they make a gain in the direction of lightness, but it is a time-consuming operation which must be done carefully. In carrying out the balancing operation, all the makers of engines weigh the rods in sets and equalize each set of rods and at the same time keep the centers of mass at corresponding points on each rod, within very narrow limits.

Crankshafts

Crankshafts are still growing stiffer. They are larger in diameter and at the same time shorter. Rutenber has a 2-in. shaft in place of a 1¾ on its standard model 25, and this is typical. This is one of the points in which passenger car and tractor practice approach each other for entirely different reasons. In the passenger car the stiffness is needed to take care of the higher speeds. In tractor work the stiffness is needed to take care of the constant racking of the engine on account of the rough work at constant maximum torque. Tractor engines must stand up. Two days may mean thousands of dollars in crop loss to a large farmer and he must have tractor engines that will work right along indefinitely.

Furthermore, on tractor work the ever-present grit and dust problem enters. It cannot be kept out in spite of washing apparatus on the carbureter and double filters in the breather pipe. It will get into the engine, and the only thing to do is to make the shaft so hard that it cannot be cut by the grit. The Waukesha motor, for example, uses a heavy chrome nickel steel shaft in which the tensile strength is carried up to 140,000 lb. per sq. in. and of a scleroscope test that almost equals tools steel.

Valve Actions and Drives

Silent chain drive has not gone ahead in the last 2 years for camshaft drives. The wide-faced helical gear seems to be about the most popular, and the use of Fabroil, Micarta and other compressed materials is looked upon favorably by a great many. The Waukesha is using a drop-forged gear, which the company believes to be best for the rough work of tractors, especially in that non-resonance is not such a great necessity. In passenger car practice, on the other hand, silence is greatly to be desired, and hence wider faces,

compressed fabric gears, the helical pitch and occasionally silent chain drive.

Camshafts have not been altered materially. In fact timing and cam contours have not changed much in the last 3 years. Where the offset rocker has been adopted it has, of course, necessitated a change in the cam, but the average timing will not be found to be much altered. There is a surprisingly small difference between commercial and passenger car work, the latter being slightly more advanced for the higher speed. Exhaust valve opening at 45 deg. before lower center is about the average, while for a few passenger cars it will run nearer 55 deg.

In construction, the valve operating parts have been made lighter. There is quite a trend towards hollow push rods. Waukesha, Northway and Falls have all adopted them this year. The high speeds of the valves have called for a reduction in the inertia of the moving parts through decreased weight. If this inertia is not decreased the followers will not cling to the cams. Steel tubing is used for the push rod, and this is fastened by welding or expanding to the solid steel-hardened follower.

Followers of the mushroom type are growing rapidly and the roller design seems to be falling off among the motor specialists. There is generally an offset on the follower to distribute cam wear. This is secured through the simple means of making no accurate determination of the push rod axial center, so the variations in the casting will give the offset.

Valves

Valve sizes, as stated before, have not changed much. There are quite a number of theories on the subject. For instance, one engineer will say that in truck motors the gas velocities have to be higher in order to take care of the lower grade fuel now on the market. Another truck motor engineer will state that the truck engine valves have to be larger in order to secure the higher volumetric efficiencies at lower speeds. As a matter of fact, practically everyone is going just as large as he believes safe in valve sizes.

Tungsten for valves is rather high in price. The natural result is experiments with other alloys. Wisconsin is using tungsten, and so is Northway, while Waukesha has found 3½

Overhead-valve Rutenber with detachable top on the cylinder. There is also a cover arrangement over the top of the valve for appearance and to aid in silencing

per cent nickel steel very satisfactory. Another concern is experimenting with chrome nickel, and a few who cannot secure the material at commercial prices are trying other alloys. There is also a strong contingent in favor of the cast iron valve.

Oiling Systems

Higher pressures are used in oiling to compensate for the higher speeds. In the engines made by passenger car manufacturers there has been a tendency towards full pressure feed. This has been followed to some extent by the motor manufacturers. The Buda oil pump delivers a pressure of 40 lb. at 1000 r.p.m. of the crankshaft, and this is typical of other practice.

In oil pump practice there has been a little uneasy shifting around, both in the pump and in the drive. The Waukesha changed to a plunger pump a year ago, but came back to the gear device. Rutenber, on the other hand, has changed over from a vein pump to a plunger. The gear pump is in the majority, with the drive taken off the end of the camshaft. Oil leads are larger and as a rule are confined within the limits of the motor.

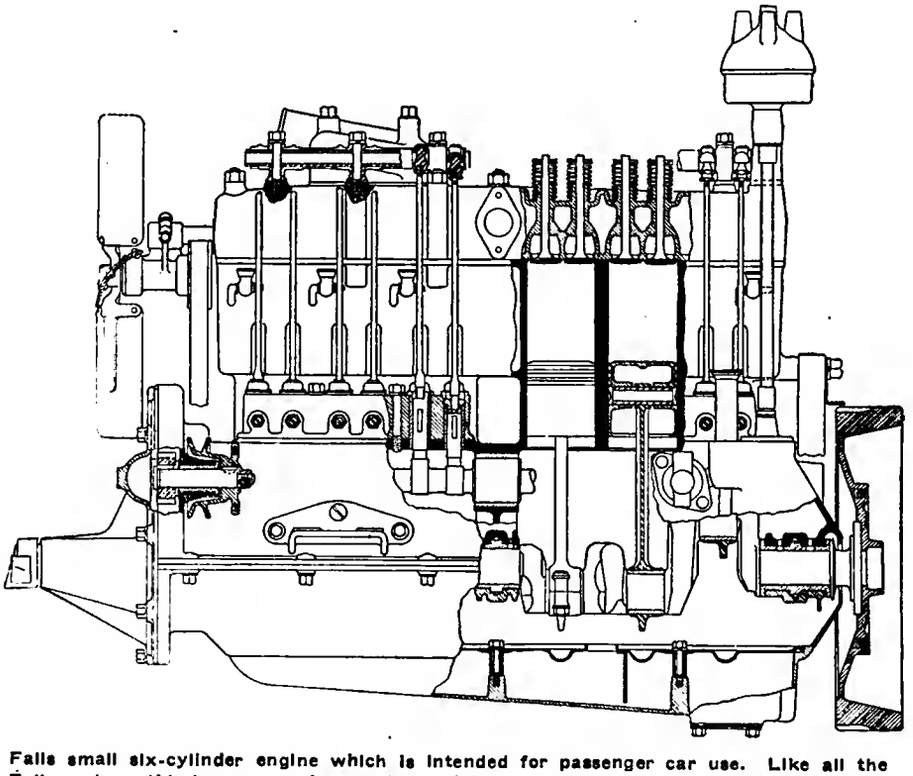
Some of the companies have simplified the oiling system to the extent of making it entirely self-contained. This has been a tendency for three years or more. The Wisconsin pump can be removed by taking four studs out of the bottom of the case. The Falls company has removed the external pipes this year and made the system self-contained. In the Le Roi engine there is a compartment surrounding the camshaft, which acts as a secondary oil chamber. It is 8 in. above the crankshaft and consequently gives that much hydraulic head for continually maintaining a supply in the splash troughs.

The matter of maintaining the oil in the splash troughs becomes very important in tractor work where a machine may be forced to operate on the side of a hill or constantly up-grade while it is running some stationary installation or, on the other hand, down hill. Waukesha has solved the problem of rectangular troughs, in which the scoop dips at the center or diagonal intersection of the rectangle. The scoop has been designed to give sufficient dip at any possible inclination.

Dust filters must be used in the oiling system of the tractor engine. Particularly is this true in the breather. One engine uses two screens in the breather pipe, the top removable and the other stationary. The continual cloud of gritty dust that surrounds the tractor is its worst enemy, and although the grit cannot be altogether kept out, every precaution must be taken. Tractor motors must be entirely inclosed for this reason.

Aeronautical

All through the motor industry there is a feeling of preparedness in the direction of aeronautical work, Although motors are in such demand that prospective automobile manufacturers have gone from factory to factory begging for production, enough time has been snatched to give the aeronautical side of the question a little attention. Wisconsin,

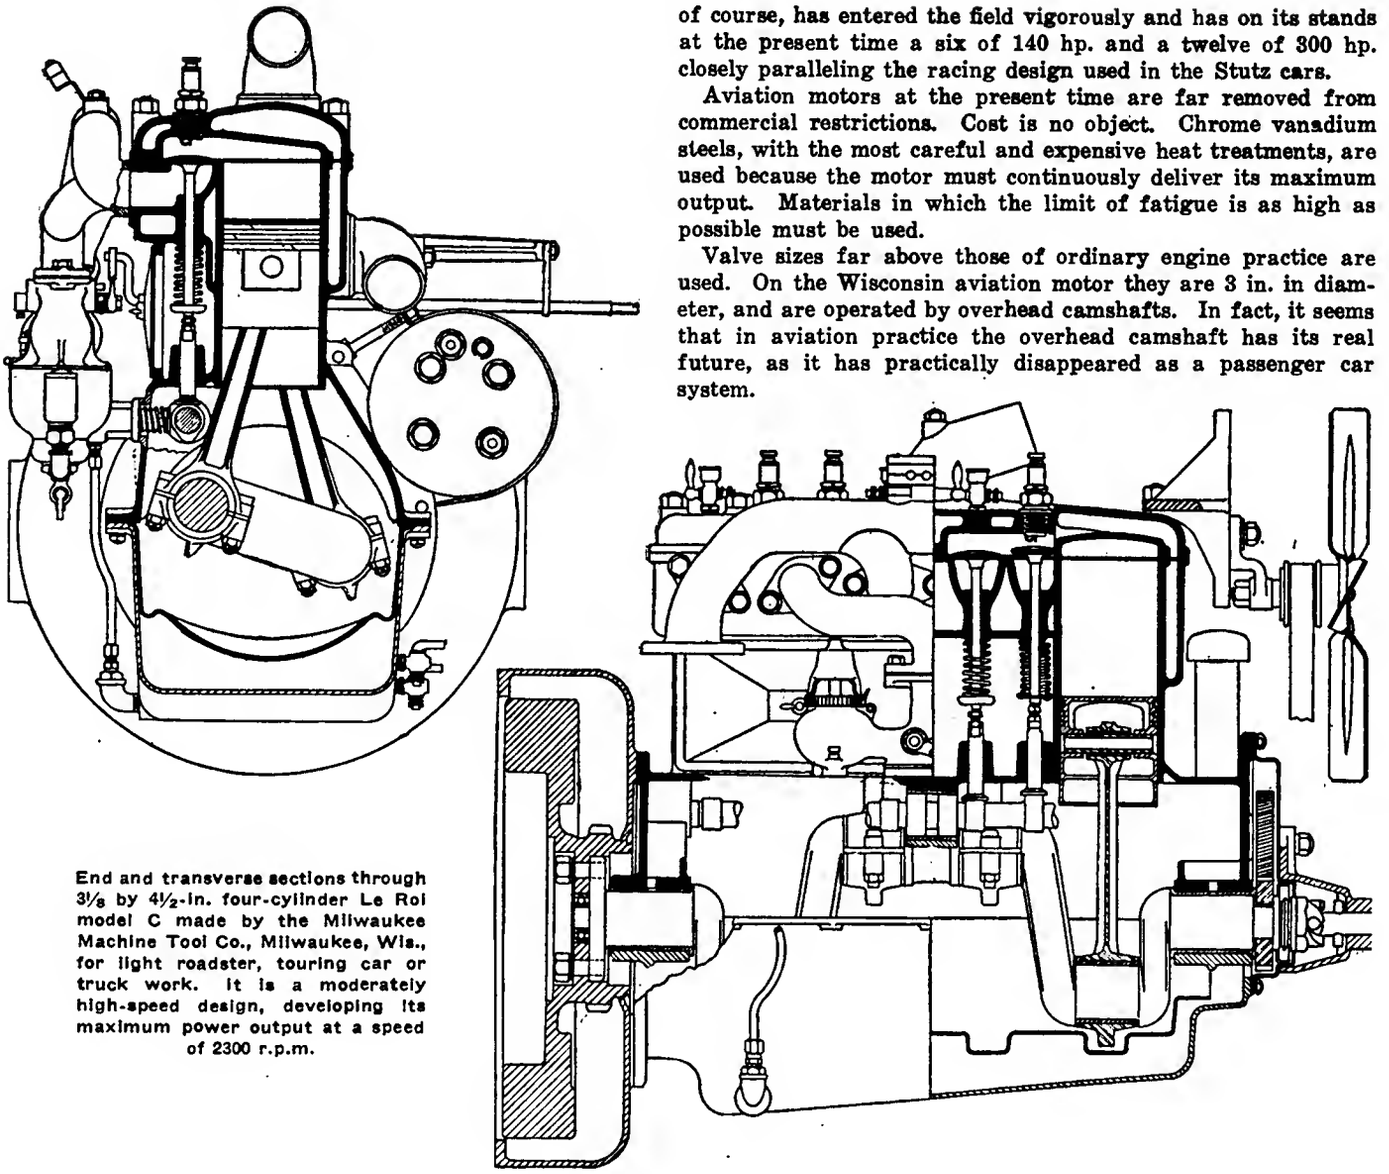


Falls small six-cylinder engine which is intended for passenger car use. Like all the Falls motors, this has an overhead valve action and a very efficient form of combustion chamber which is clearly shown in the end cylinder

of course, has entered the field vigorously and has on its stands at the present time a six of 140 hp. and a twelve of 300 hp. closely paralleling the racing design used in the Stutz cars.

Aviation motors at the present time are far removed from commercial restrictions. Cost is no object. Chrome vanadium steels, with the most careful and expensive heat treatments, are used because the motor must continuously deliver its maximum output. Materials in which the limit of fatigue is as high as possible must be used.

Valve sizes far above those of ordinary engine practice are used. On the Wisconsin aviation motor they are 3 in. in diameter, and are operated by overhead camshafts. In fact, it seems that in aviation practice the overhead camshaft has its real future, as it has practically disappeared as a passenger car system.



End and transverse sections through 3⅛ by 4½-in. four-cylinder Le Roi model C made by the Milwaukee Machine Tool Co., Milwaukee, Wis., for light roadster, touring car or truck work. It is a moderately high-speed design, developing its maximum power output at a speed of 2300 r.p.m.

Schoenrock Uses Two-Diameter Piston and Two Sets of Valves

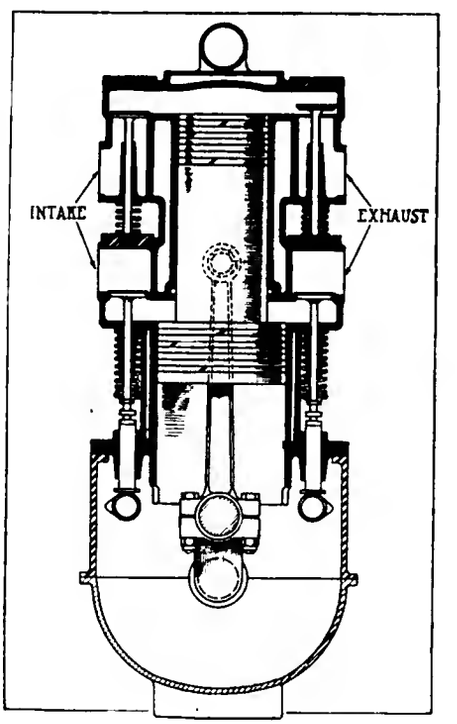
THE section at the right of the page illustrates the Schoenrock engine, which incorporates a novel adaptation of the four-cycle principle. The object of the engine is to secure the benefits of four-cycle practice with twice the number of expansion strokes. As will be seen, there is no great difference between this engine and any other except that it has a two-diameter piston, the smaller diameter being at the top and acting as the seal for the expansion chamber while the larger piston is at the bottom and is merely a factor in the scavenging of the engine.

Piston a Unit

There are two sets of valves, the upper left and lower left being intake and both right valves exhaust. The double piston is a unit so that as the gases are expanded they act upon the same rod, transmitting the power to the crankshaft. On exhaust the flow is very much the same as on the ordinary four-cycle engine.

May Be Rotary

In operation, as already stated, the engine has twice the number of expansion strokes, this being gained by the fact that while the small piston is compressing the gas the larger piston is exhausting the burnt gases. Although this drawing shows the engine with poppet valves it may be constructed with rotary or any other type. The intake valves are at the left of the cylinder block and the exhaust valves at the right, as indicated in the illustration. The connecting-rod mounting is also shown in the drawing.



War Develops German Industry

Necessity for Economy in Metals Makes Chassis Design Simpler, Stronger and Lighter—Lack of Rubber and Other Materials Brings Out Synthetic Product for Tires

By E. A. Langdon

GERMANY'S automobile industry has played a part of the utmost importance in enabling that country to withstand the assaults of its enemies since the beginning of the war. Needless to point out, this industry has not escaped the influences and effects of the great conflict and these results of the abnormal conditions created have been of both a detrimental and a beneficial character. For example, most of the cars which were drafted for service at the beginning of the war have long since been consigned to the army's great clearing houses for material, where they have been dissected and their various units used for other purposes or in repair work, or the rusty skeletons of their chassis, plucked bare of every detachable part and accessory, are gradually disintegrating in the mire of a thousand battlefields.

Chassis Are Simpler

Chassis construction has undergone a marked change, both in design and materials employed. Chassis are stronger and lighter, due to the elimination of many special parts formerly used, but now discarded for reasons of economy, and also because of the marked increase in the use of aluminum, not only for crankcases, gearboxes, etc., but also for such parts as valves, shafts, cylinder castings and other units for which an immense amount of copper, steel and iron was formerly required. A number of aluminum alloys of great strength has made this wide use of the metal possible, one of these alloys closely resembling the qualities of steel.

Gas from Coal for Fuel

An ingenious method of supplying automobile fuel has enabled the Germans to solve the gasoline shortage problem, which has at times remotely threatened to become serious since the beginning of the war, in spite of the enormous quantities of the fuel which Roumania practically made a compulsory condition to the purchase of wheat by Germany. Gas distilled from coal, and somewhat resembling illuminating gas in a liquefied or highly compressed state, is carried in steel tanks and fed to the engine through reduction valves.

One of the most important developments directly due to the war is claimed by the Germans to be the perfection of the manufacture of tires and other articles in which rubber was formerly used by synthetic processes. They also state that this product will compete successfully in quantity and quality with natural rubber in the world's markets following the termination of hostilities.

Industry Is Concentrating

German automobile, parts and accessory manufacturers, as well as the truck builders, are being fused into a powerful, compact unit of industry and are counting on their co-operative abilities to overcome trade barriers existing against their products at the end of the European struggle. It is even possible that agricultural and commercial motor trucks and tractors will represent a majority of the products of the industry for two reasons. One of these reasons is the large demand for these machines due to the scarcity of horses caused by the war, and the other is the economical advantage of standardized production.

Army Cars Different Now

The automobiles used by the army, at the present time, differ considerably from those used at first. Needless to state, there is hardly a car left which was drafted for service at the beginning of the war, except a few luxurious private cars used by the officers of the general staff and German princes. The supply of machines, however, must be replenished, and it is remarkable how, under the stress of necessity, German engineers have given up more and more special parts which went to make the machines as nearly perfect as their builders could conceive them; hence the cars are approaching an ideal of strength and simplicity, both in regard to design and materials used.

Aluminum Widely Used

The most striking feature, perhaps, is the immensely extensive use of aluminum, not only for crank and gear cases, but for valves, shafts, cylinder heads and jackets, supplanting a great deal of copper, iron and steel used before. The reason for the usefulness of aluminum is that the Germans have developed a number of very strong alloys, one of which is said to closely resemble the qualities of steel. The economic side of the matter is that the Germans mine coal belonging to France and to a considerable extent by French labor, and this coal enables them to manufacture tremendous quantities of aluminum cheaply by the electrical process.

This cheap production on a very large scale of coal has also aided the Germans to cope with their shortage of gasoline, as the gas obtained by distillation of the coal is used very largely to replace gasoline in stationary engines, marine engines, etc. This gas, which resembles liquefied or highly compressed illuminating gas in many respects, is transported in steel tanks from which it is drawn through suitable reduction valves. The reason for using this gas instead of industrial alcohol, which was used so widely in the early months of the war, is the necessity of economizing in potatoes, the chief staple food of the German people.

Synthetic Rubber for Tires

Rubber, the Germans say, will rapidly become a matter of the past after the war. All the tires used on German cars, as well as all the other rubber articles required by the Central Powers, are now made artificially, or rather synthetically. The Germans promise quite seriously that in the future their product will equal in quality and compete very successfully with Para and Ceylon rubber, and they never grow tired of repeating, with grim sarcasm, the fact that they are obliged to their enemies for forcing them to develop rapidly an invention which otherwise might have come along slowly in the course of years.

It has been stated above, and in some earlier article as well, that the Germans are organizing their industries more

and more on the "American," that is, the centralized, concentrated plan, and that by this means they intend to overcome whatever barriers they might have to break down in the market of the world when the war is over. This applies to the automobile industry as well, and in all likelihood, it will, after the war, face the world market as a solid combination, or "Kartell," as they call it in Germany—which is very little different from a trust. On the other hand, it is not at all impossible that the whole German automobile industry will devote itself to just one class of work, or chiefly so, namely, the building of trucks for agricultural and commercial uses.

The Need for Trucks

That the need for commercial motor vehicles will be even greater than for pleasure cars, after the war, follows simply from the fact that the stock of horses, with the exception of the breeding specimens, will be practically killed off by the time the war is over. Besides, the farming population, and especially the smaller ground holder, will be very much dependent on government support in every form, and as the subsidy policy for automobile trucks will doubtless be continued with even greater vigor than it was begun before the war, the incentive for buying efficient modern equipment will be correspondingly increased.

While the beginning of the war, or, let us say, the first 12 months, saw the introduction of many new devices and processes of warfare, such as movable siege guns, asphyxiating gases, liquid fire, electric barbed-wire entanglements and so forth, the number of innovations in war technique since the end of the first year have been rather small. The reason for this is not quite easy to understand, but, as several officers of the engineering branch of the German army have put it, is just about this:

Trying Out the New Things

"Germans, Austrians, French, and, in spite of their denials, British, have for years preceding the war invested an immense quantity of study and labor in the possibilities of the present war, and according to their ideas of the problems it would present, have worked out different schemes to overcome the difficulties they assumed they would have to face. Consequently, as the different ideas of warfare were given reality by the war's first year, the different inventions and discoveries and methods, either perfect or made so during that period, were brought into action. This introductory period being past, and the gravity of the struggle centering upon the Western field, methods had to conform to the situation given there. What is this situation? You may liken it to a game of chess on an immense scale, a game in which each player according to known ways of playing is capable of checkmating his opponent at the latter's first grave mistake. Hence the endless feeling-out and experimenting on both sides. Now and then, one or the other player believes to have found a new solution, but upon attempting to put it into practice finds, sooner or later, that he has not gaged the situation correctly. It is simply the impossibility of solving a problem of strategy by tactics. Therefore, whatever technical improvements one side or the other may bring out now, can be of but little bearing on the result. Both sides realize this, but the difference is that we are ready to express our understanding of the situation."

These words are almost verbatim what the writer learned from a high "genie" officer, now retired because of injuries. The interview took place in September, and the writer having obtained some English papers in Holland a few days before, asked the colonel above quoted: "How about the new British 'tanks'?"

The British Tanks

The officer stroked his long mustachio, and answered slowly: "It is quite a novel development, and its full efficacy cannot as yet be approximated. But if you want my opinion of the 'tanks,' let me tell you that on the Western front, two things count, men and explosives. Other devices are entirely minor. The men being required to serve the machinery of war, the rest consists in blasting to bits as much as possible of the enemy's position. Whatever is not an explosive is subject to destruction by explosives; and all we can tell after a few days' experience, so to speak, with the 'tanks', is that this maxim holds good in their case. They move slowly, at hardly more than 5 miles an hour, and that makes them splendid artillery targets."

I requested the colonel for a description of the "tanks."

"Mind you, this is far from being exact. Well: they are about 65 ft. long, almost 10 ft. high and not much narrower. The most striking feature is propulsion by endless steel lattices, engaged in the manner of chains by a set of driving wheels arranged on each of the axles. Steering is by a central pair of wheels placed like that of the old-time tricycles and arranged back of the machine. The power plant is situated close to this third wheel, entirely out of view from in front, and I conclude that the driver is guided by a sort of periscope eye placed in a well shielded position at the front of the machine. I doubt whether this engine weighs less than a 4:4:2 type of locomotive, and therefore would easily require 400 to 600 hp. for driving it. I know that Allied journals state the machine is like a railroad engine and carries its own rails along. But this is not so. These 'rails' are continually being laid over the most torn up ground imaginable, and the simile would be more correct if they would say that traction is by means of a pair of wheels, one on each side, with a theoretical spoke length of several hundred feet, but so actuated as to overcome the difficulty which this radius would cause if power were applied at the geometric center of the wheel. We have not as yet captured a 'tank', chiefly because when—as it happened in several cases—a 'tank' gets beyond control, it is blown to smithereens by the army of which it is part, so as to keep us from capturing it. Hence, you understand, all these statements are, so far as the construction is concerned, a matter of deduction. I should not be surprised, however, if these huge machines were driven, instead of by gasoline motors, by Diesel engines. By the way, isn't there a similar tractor made in the States?"

An American Prototype?

I failed to recall at the moment. The colonel gave me a merry look, like a schoolboy finding that there is one thing he knows and the teacher does not, and opened a drawer of his office desk. After a few seconds he handed to me a catalog of the Holt tractor factory! There was an illustration of what no doubt served as the original type for the "tanks," the caterpillar drive used on an American agricultural tractor.

The privates, "Kanenenfutter," who return from the trenches for a brief furlough to the "hinterland," are less easy about the new fighting machines. They maintain that when the "tanks" were first introduced, they made quite a terrible impression on the soldiers in the trenches, and it took quite a while until the suitable artillery could be got into readiness. But now the "tanks" are said to be a normal feature of the fighting like poisonous gases, and the soldiers with their marvelous faith in the ability of the army's rank feel certain that very shortly their effects will be quite checked and possibly beaten by a counter-invention. But there, the words of the engineering officer will probably prove true.

Friendly Toward America

A remarkable feature of the situation at present is the feeling toward America. The antagonistic sentiment which existed about a year ago has very much subsided, and the ideas then prevalent, about "*révanche*" toward America, for

supplying the enemy with ammunition and for restricting the submarine warfare, have almost disappeared, and by the intelligent Germans are passed over with a slight embarrassment. When you ask them about it, they say that they are so certain of their success in the end, that they will need their energies for something else than hitting back, after the war, at who might have harmed them during the war. The fact is, they realize that they will need very much raw material when the seas are open once more, and that it is no use antagonizing the people from whom you will have to buy most of it and who will find customers aplenty.

Big Tariffs in Europe After War

Of course, trade, like everything else, will be very different after the war. New methods will have to be used, both in buying and selling, and especially will the matter of credit and payment be altered. After the war, especially where such articles as automobiles, and particularly trucks, are concerned, a considerable part if not most of the business will be done on a basis of instalment payments from the consumer. In other words, American exporters here will meet a similar condition to that prevailing in South America, where payments are on long terms. It is not improbable that the same condition will apply to all of Europe, at least the Continent; and hence, exporting will call for more capital than it did before the war. Add to this the likelihood that every one of the European States or groups of States will surround itself by a tariff wall, and it follows that business with Europe after the war will be, although big, yet not an easy matter to transact, nor will it present any opportunities for the get-rich-quick type of business man.

Preparation Is Imperative

It would be well for the American automobile manufacturer who is at present reaping handsome profits to look into the future, organize his plant in the most efficient and economical manner imaginable, study the past methods required in trading with different European countries and educate their working, selling and advertising forces with a view to taking up the hard work of exporting when opportunity will present itself. In this regard, the parable of the wise and foolish virgins will once more prove significant, as it has proved so many times in the past.

Merchant Marine a Necessity

In closing, the writer would like to add one more thing which, though not of immediate automobile nature, should make American manufacturers think. American business men, not only in Germany and Austria, but also in Holland, Switzerland and Scandinavia are continually bemoaning the fact that there is so little of an American merchant marine with ships plying between the old and new world. They fail to see why their business, often enough in merchandise which cannot in any way be construed to be contraband, should be paralyzed and, as it was in many cases, destroyed, because nations other than their own are at war, and things seem to have come to the point where the belligerents force neutrals to look out for every one's interests except their own.

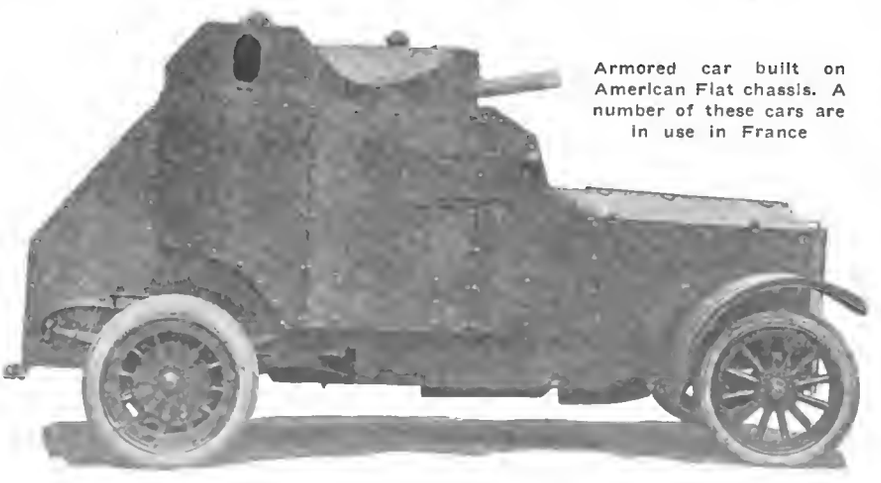
Fiat Armored Trucks in Battle Service

AMERICAN automobile chassis are numerous on the battlefields of France, both as the conventional passenger car and covered with armor plate. These armored cars are built both on motor truck and passenger car chassis, depending upon the character of the service for which they are intended. Thus massive, heavy chassis are used for field work where thick, weighty armor plate is a necessity, due to possible exposure to heavy fire and where speed is a secondary consideration. For swift, light armored types powerful passenger car chassis are frequently utilized, the plating not being as heavy since these cars are usually employed for scout work and quick dashes, so that they are not called upon to sustain heavy rifle or artillery fire for any length of time.

A number of the armored cars now in service in the Somme district and around Verdun are built on Fiat chassis produced in the American factory of the Fiat Co. at Poughkeepsie, N. Y. The illustration shows one of these Fiat armored cars. The motor is a 55-hp. type; wheelbase is 128 in.; transmission four-speed; and clutch multiple disk. In fact, the chassis with the exception of heavier springs, dual rear wheels, and the double steering controls, is identical with the model 55 passenger car chassis which the Fiat company is producing as its regular standard car. The chassis is equipped with the regular forward steering, so that the front driver operates the car as under ordinary conditions. There is a rear steering arrangement, so that the second operator facing backward at the rear end of the car can steer the car backward and have the car under the same control as the front operator—the advantages being that the armored car can run up as close to the firing line as desired, use the turret guns, and immediately back straightaway without having to turn around and subject the car to broadside firing from the opposing lines.

The radiator at the front of the car is armored with a V-shaped plate, so that any bullets striking will be deflected, without doing any damage.

On the chassis are mounted two rapid-fire guns in revolving turrets. Both the front and rear operator are protected by shields over the slits in the armor plate, through which they may look while under fire. The front operator has an opening, which is kept open when not in danger, but which can be closed down to the minutest point when approaching the firing line, giving almost perfect protection.



Armored car built on American Fiat chassis. A number of these cars are in use in France

The chassis is equipped with dual wheels rear, single wheels front. No air is used in the tires, so that puncture is not as serious as with air-filled types, the regular casing being filled with a special filler material adopted by the English government, although these tires are mounted on demountable rims for quick changing if necessary.

More News Is Wanted in Advertising

Value of a Good Name Considerable—Important That Price Be Stated—Foolish Catch Words Usually Disliked by Buyers

THE difference between American and British advertising is generally accounted for by the statement that the latter is "English," which explanation is given for anything and everything that the Briton does in his own way. But that the English ad reader is just as keen as his American cousin for attractive advertising and for ads that "tell him what the thing can do" and what it costs is indicated in a letter to *The Motor*, England, from one of its readers.

He advances the very modern thought that there is not enough sympathy between the advertiser and the prospective buyer, a criticism that is not necessarily confined to the British Isles. "One often wonders," he says, "whether the advertisers can regard their efforts from the standpoint of the buyer.

"The commercial value of advertising cannot be too highly esteemed. To be known is essential, and since first impressions have a peculiar adhesiveness, much—very much—depends upon one's introduction to some new commodity placed upon the market. Makers vie one with another to outdo in attractiveness, to excel in superior claims, to show their goods in the fairest light, and thereby eclipse the less-dazzling efforts of their rivals.

"Apart altogether from any commercial or speculative purpose, the scanning of the advertisement pages of such a paper as *The Motor* is full of interest, and one often wonders whether the advertisers can regard their efforts from the standpoint of the buyer, and whether they fully appreciate the effect upon the general mind. Sometimes one feels convinced that there is an absolute want of sympathy between advertiser and purchaser.

Must Attract Attention

"To attract attention to an article is the primary intention, and this may be accomplished in various ways. At the one extreme is the depicting of the absurdly ludicrous, freak forms and figures and faces, distorted and grotesquely abnormal features; but the effect of these, though at first they may succeed in drawing attention, is to repel; and probably every motorist could name a list of good and useful articles which are studiously avoided simply because of the advertiser's design which offended the sense of propriety.

"Just now, too, the figure of a man of good stature and military age at once arouses the thought that he ought to be at the Front and not soliciting a purchase of his goods. To rescue old gods from the backwaters of mythology and equip them in extremely modern guise adds no fascination to the goods they are supposed to adorn. It is always a risk to insert a face as a winning feature of an advertisement, unless that face have some peculiar charm or virtue. Some advertisers, not necessarily in the motor line, have ruined their chances of success by publishing abroad their own likeness. We often enjoy more fully goods, as also literary or poetic work, when we have not seen and do not know the manufacturer or author. Some geniuses in the factory and at the desk are insignificant to the eye. Nature, at times sparing in her natural and physical gifts, has bestowed vast stores of mental ability upon her unbeautiful children.

"An advertisement may be both attractive and pleasing. There are some we have turned to again and again simply because the illustration took pleasurable hold upon us, and, unconsciously, we became favorably disposed toward the thing itself. High art has been enlisted in this work of advertising, and a sense of gratitude toward the advertiser has led to the use of his—possibly—inferior goods to the complete exclusion of better things unhappily proclaimed.

"There are firms who cling to the idea that antiquity is still a virtue in the market, and largely declare their goods "The Original," even going to the extent of naming the date of birth or the age of the thing described; and the public, knowing that it is experience which teaches the most useful lessons of all, and that a hundred minds are ever busy in a more or less successful effort to improve upon any commodity which has attained to favor, prefer goods of the same kind whose making has no marks of antiquity.

"What's in a name?" is a stereotyped question; but there is more in the naming of an article than some makers think. It would not be a difficult task to draw up a fairly long list of articles which one would not care to ask for simply because their names are awkward or foolish. Give a thing a simple, straightforward, harmonious name and the battle is at least partly won. When people are uncertain how a word is to be pronounced, they hesitate to use it; and if that word be a foreign word, whose mispronunciation would be a mark of lack of education, educated people will shun it, even though it mean inconvenience and disadvantage to themselves, for fear of a slip.

"A man's own name is not by any means necessarily suitable for his goods. Who would not hesitate to inquire about the "Mary Ann carbureter" or the "Simple Simon tire?" The failure to appreciate things aright—a failure which is disastrous from the sale point of view—is shown in such nomenclature as the "Little Nell motor clog" or the "Tiny Tim differential grease." These may be fantastic exaggerations, but they have their counterpart in the advertisement pages of some journals.

"What the buyer really wants to know is the need that the goods will meet, claims that have borne the test, while one is also willing to accept with the usual scepticism the ambitious expectations of the makers. These have, however, been carried to such an extreme that the inquiry columns of many papers are full of requests for the experiences of disinterested users as to whether the advertised commodities actually fulfill the promise or claim of the advertisement.

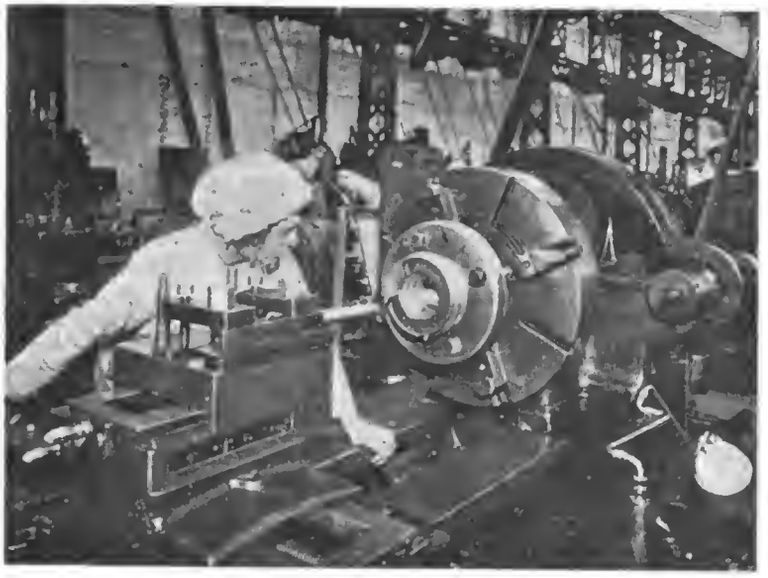
State the Price

"One thing more, and that is the price. Why cannot advertisers state the price of their goods? The withholding of this all-important factor is undoubtedly detrimental to the salesman. It creates suspicion. It is said that many shop windows show no prices on their goods because the sellers vary the price according to the apparent spending ability of the customer, or because the instructions are to ask at first too much in order to secure custom by reduction. These methods will not do to-day. We want to know exactly what a thing is to cost; we shall then know whether it will be worth our while to buy. The bartering of the Eastern fair is not according to the genius of the Western buyer. Advertisements count, advertising largely controls the market; but, after all, it is worth that wins, and the advertiser who gains a large sale by fraud or deception will suffer for it in the end."

Should Use More Female Labor

Automobile Manufacture Comprises Many Operations Which Can Be Performed Equally as Well as by Men —Hours Should be Shorter and Pay a Little Lower

By H. W. Allingham*



Cutting a large square thread

THERE are, in automobile manufacturing, many lighter jobs which could be done quite as well by women as by men. Such work should be paid for at a higher rate than it has been the practice to pay for woman labor, but at a slightly lower rate than men would expect for the same work, and the woman's hours should be a little shorter, perhaps 44 hr. a week where the men work 48 hr.

In showing how the above decisions have been arrived at it will not be possible to avoid repeating much which has already been published in the daily press and in weekly and monthly magazines. It is, also, not proposed to attempt to argue that the automobile industry is more suited to the employment of female labor than any of the other industries at present employing male labor almost exclusively. In fact, all the arguments which may be put forward in favor of the employment of women in the automobile industry, apply with equal force to a large proportion of the world's industries.

Until the European war forced upon the European nations a careful consideration of the possibilities of employing women, it had been the custom there, as it is at the present time here, to assume that certain classes of work were "men's work," simply because men had been customarily employed on such work since its inception.

A consideration of the question as to whether such an assumption is based on any logical reasoning shows that in the majority of instances it is not. Whether work is suitable for female labor or not is dependent on two main considerations.

(1) The manual effort required.

(2) The skill required.

Consideration of 1 needs no amplification. 2 should be analyzed further. In general it has been found that the more skilled manual work of the world must be planned on the assumption that male labor will do it. The reasons for this are as follows:

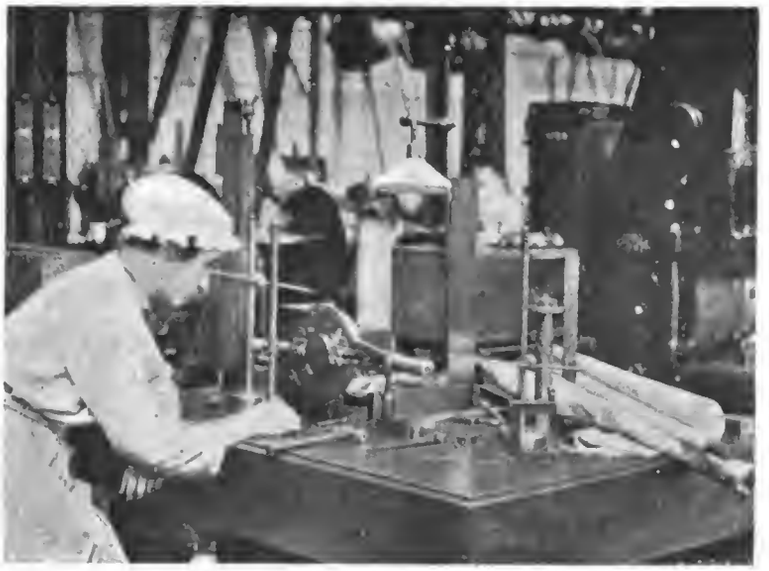
a. By virtue of the skill required, a more or less lengthy period of apprenticeship is required, during with the worker is an expense rather than a dividend-earner. It therefore follows that it is desirable to employ such people on skilled work as may be reasonably expected to remain active producers for a large part of their lives. This rules out women in general, because of the belief that they are more uncertain than men, practically never working after they marry.

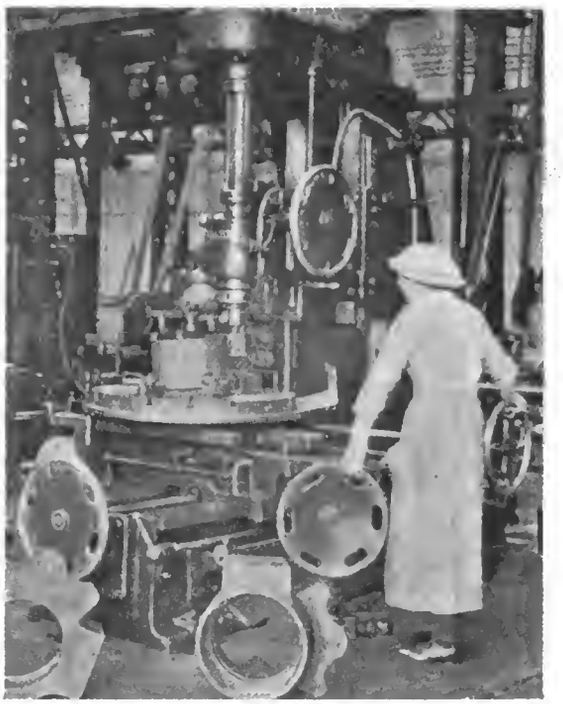
b. Ever since the inception of the "factory" systems less than 100 years ago men have banded themselves into unions which have tended to limit the employment of women, and of unskilled or semi-skilled men.

Mechanical engineering, covering foundry, machine shops, etc., has, in the past, almost without exception been looked upon as work suitable for men, although in the specialized industries, more particularly in the higher branches, women have been employed regularly for many years. Examples of this are light brass-finishing, core making, etc., while in the electrical trades much of the light work is now looked upon as women's work. The real difficulty is to determine how far it can be extended. For example, there can be no two opinions as to the fact that the machining of a 6-in. shell weighing 140 lb. is not suitable work for women, from the point of view of manual effort required, although it may be from the point of view of skill.

Performing surface grinding operation

*Mr. Allingham is a consulting production engineer with a very wide experience both in Europe and in America. He is especially well acquainted with the automobile factories of America and of England, while he has been able to study at first hand much of the work now being done by women in Europe.





Extremes of work. Above, the operator is illustrated engaged in marking off, and at the right in handling heavy parts

Again the operation of high-speed-steel hardening furnaces, or relieving lathes, can scarcely be expected to be sufficiently standardized, except in occasional instances, to be suitable for female labor. Nevertheless the writer in his own factories has been agreeably surprised to find women handled all the above work with every success, after careful teaching. The strictly logical line to follow would appear to be, firstly to determine what may be considered the limit for a woman in regard to manual labor, and then it becomes a question of balancing up the objections of trades unions and the difficulties of teaching.

Overcoming Objections

As an example of how male workers may be handled in this connection, I will give an instance which occurred in a factory where I was production engineer some 5 years ago. The department in question was the manufacturing milling department, and the labor regularly employed was of the semi-skilled or "machine operator" variety. Some of the work had increased in volume very greatly, and we had put in jigs holding, say, fifty small pieces, one jig being filled while the other was cutting. The work was light, and labor was scarce. Realizing that to start girls on these machines would be an innovation at that particular shop, and likely to cause trouble, I called a meeting of all the men involved, and asked them what their objections would be. They had all the usual objections and, of course, said they would not work if women were introduced. I went in detail into the orders in the department and through the capacities of the machines as shown by stop-watch time-studies (already this practice for setting rates was accepted by the men) and gave them one week to bring in their male friends to man the machines. If they could not give us the output required then, we should have the right to start women, *giving the preference to the men's sisters and friends.* The result was twelve women out of forty workers within a month, the women's work being carefully selected so as not to clash with the men's. No trouble was experienced and the men could not be rude or rough to their own relatives.

The average results of this and dozens of similar experiences can be set out briefly as helping to point the way to future developments. 1. Women will handle small delicate work of a repetition nature more quickly than men, giving a larger output per hour.

2. Women should work shorter hours than men. In general 8 hr. are quite enough, and a 44-hr. week, with Saturday a half day is my present ideal, just as the 48-hr. week is long enough for men working at an efficient speed.

3. The task per hour for women on light work should be as high as for men.

4. Rather heavier work can be tackled by women at a rather lower speed per hour.

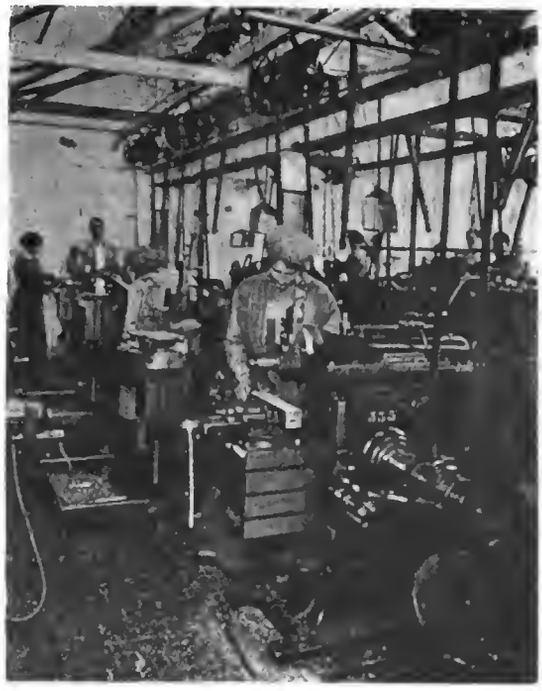
It is doubtful, however, whether the need for women to undertake what I describe as rather heavier work would arise if they were regularly employed on light work. There is so much light work in the world at present done by men that this, at any rate, merits the first consideration. For instance, the custom in some countries of using women for snagging and fettling castings while men are doing plain light engine-lathe work in the same factory, seems to be quite wrong. The great increase in quantity production in the automobile trade has caused a splitting up of operations, and a state of standardization of small operations has been reached in many factories to such an extent that workers entirely unfamiliar with factory methods can learn to perform the operations quickly and skillfully in a very short time. When these operations are light and do not involve much strength, there would seem to be no logical reason why men should be employed in preference to women. Such operations include almost all the light machining operations on such parts for instance as valves, aluminum pistons, etc., and light assembling operations on units.

Light Machine Work Suitable

The classes of machines capable of being efficiently operated by women are the lighter varieties of drills, milling machines, plain lathes, punch presses, special continuous operation machines and hand screw machines; automatics are not among those recommended to be considered at first.

In regard to assembling, much of the electrical work and top making is now being done by women, and the extension of women to the other components would appear a logical step. For example, the assembling of the connecting rod and piston, of pumps, of carbureters, even of the differential gear and steering gear, would not on the face of it appear to afford any difficulties.

The question of the reduction of wages paid is an economic one, but must be mentioned here, as it will be one of the great



Women operators doing what was formerly men's work, shaping small parts and grinding in valves of truck engines

causes of objection to women labor on the part of the labor unions. The fact that women have received lower hourly wages in the past has been due to the fact that so large a proportion of female workers have not been entirely dependent on their wages, and also that a very much smaller percentage of women than of men have dependents on them. Thus a girl of 18, one of a family, goes out to work. She is living at home, and a wage of $7 a week is almost all pocket money to her and she would not trouble to join a union if there was one. From the above, many people argue that it is quite logical that women should receive lower wages than men, because wages are dependent on supply and demand.

It is this same supply and demand which has caused the writing of the present article. The supply of male labor is unable to meet the demand. This has caused the wages offered to increase out of proportion to the increase in the cost of living, but still we have the alternatives:

(A) Curtail output

(B) Employ women

(a) is unsound from every economic standpoint because it is tantamount to limiting the production of wealth. We are therefore driven to adopt (b).

Now comes the question: Is it best for the country at large that where male labor is replaced by female labor, the wages, or piece work prices, shall be the same as previously, in which case the costs will remain the same, or shall the wages be in accordance with wages paid to women doing work requiring similar physical and mental ability in other trades? If we pay the same wages as men, we may embarrass all the other industries employing women, while if we pay wages similar to those in other industries we cause dissatisfaction to the men previously doing the work.

Must Compromise

The writer's belief is that a compromise will be effected. The wages paid at present for semi-skilled or un-skilled work are proportionately higher than those paid for the highly skilled tool-makers, for example. The reason for this is that the semi-skilled work has been increasing at such a rate that operators could not be obtained without offering big rates. If the semi-skilled work be now subdivided into light and heavy, we can leave the rates for heavy as they are now, and the light work should be logically somewhat lower-priced. In addition, the total wages earned by a woman are reduced, if she works shorter hours than a man, as she should do.

On the other hand, I believe wages paid to women in the past have been lower than they should be, and the widow who has been compelled to try and keep her family on the wages she could earn has been in an almost impossible position.

To sum up; automobile manufacture has expanded so much of late that there is a distinct tendency to a shortage of semi-skilled labor. There are many branches of the work at present done by men which could just as well be handled by women. Women should work shorter hours than the men previously employed on the work. Wages should be slightly lower than those received by men, but not so low as were customary before the war. Finally, present war wages should not be taken as a criterion, although the shortage of male labor will continue after the war.

Women employed in an English factory fitting crankcases of large aviation engines. They are very successful at work of this character

Committees Manage Perfection Spring Co.

System Eliminates Individual Management of Departments—Administrative Committee Supervises the Other Twelve—Each Committee Meets at Least Once a Month—Duties Outlined

THE Perfection Spring Co., Cleveland, one of the largest spring producers, is operating its institution under a form of committee management installed during the past year as briefly mentioned in THE AUTOMOBILE several weeks ago. The system aims to eliminate individual management of each separate department and to substitute for it a supervision of the various departments by means of committees composed of officers and employees and arranged and controlled by the administration.

The administrative committee includes Christian Girl, president and general manager; W. E. Perrine, assistant general manager; P. A. Connolly, secretary; T. E. Borton, treasurer, and H. H. Newsom, works manager, and is the supervising committee over all, determining the other committees, their responsibility, range of supervision and the departments directly under their control.

There are in all thirteen committees which are classified as administrative, finance, sales, manufacturing, engineering, standard engineering, purchasing, safety, welfare and employment, patent, salaries, sport and recreation, and cost and efficiency. Their range of duties and composition are:

Administrative Committee—

Officers of company—Supervision of all committees.

Committee on Sales—

Sales department and road engineering department—reports directly to the president or assistant general manager.

Chairman—the president.

Committee on Manufacturing—

President, assistant, general manager and works manager—supervises standard manufacturing and new process and development work and reports directly to president or assistant general manager.

Detail prints and schedules for manufacturing shall be given the manufacturing department by the order department. This department shall have charge of the cost department with the chief cost clerk as its present head. Stock room and receiving department are under the direction of the manufacturing department. It shall handle all stock and tools entering into the production of springs.

Chairman—the works manager.

Committees on Engineering—

Research committee, standard engineering committee.

Research committee includes designing and analysis—consists of the head of the laboratory, head of the experimental spring department and others that the chairman might desire.

Standard engineering committee has as its duties the active work of designing springs in process of manufacture—consists of chief engineer, road engineers and inside engineers and reports directly to J. G. Utz, chief engineer.

Chairman—the chief engineer.

Committee on Purchases—

Composed of assistant general manager, secretary and works manager. Has as duties the purchasing and directions of all purchases. The purchasing department is in charge of Mr. Homan who is directly responsible to the committee. The department has one man assigned to the purchase of factory supplies and tools for the manufacturing department.

Chairman—Assistant general manager.

Committee on Safety, Welfare and Employment—

Composed of the secretary, assistant general manager and works manager.

It is the duty of the committee to take such action as will safeguard employees and eliminate or reduce accidents to a minimum.

The committee on welfare will assist and look after the welfare of employees and their families.

Employment committee shall pass upon and handle such employment problems as come outside the scope of the regular employment agent.

Chairman—The secretary of the company.

Committee on Patents—

Composed of officers of company and engineers.

Its duties are the supervision of the application and prosecution of matters referring to patents and the investigation of all patents submitted from outside sources to the company with the power to recommend purchase or rejection. Patent attorney expense is authorized by this committee and invoices audited by it. Patent department is in charge of the chief engineer who reports to the committee.

Chairman—The chief engineer.

Committee on Salaries—

Composed of president, secretary and assistant general manager.

Duties to handle all matters pertaining to salaries.

Chairman—The president of the company.

Committee on Sport and Recreation—

Consists of assistant general manager, secretary and works manager, and also the manager and assistant manager of each team.

Duties consist of arrangement for every kind of recreation such as baseball, bowling and other features which are financed by the company.

Chairman—The works manager.

Committee on Cost and Efficiency—

Composed of works manager, assistant general manager, secretary and two employees.

Duties consist of investigation into costs and efficiency systems.

Chairman—The works manager.

The president and assistant general manager are members ex-officio of all committees whether mentioned or not.

Any committee may appoint a sub-committee upon approval by the president or assistant general manager and all committees are governed by the general executive committee composed of the assistant general manager, who acts as chairman, and the sales manager, chairman of the engineering committee, chairman of the manufacturing committee and the chairman of the finance committee. It has charge of the execution of all matters pertaining to the sale and manufacture of the company's product as directed by the policy of the board of directors, which is represented by the president.

Each committee meets at least once a month and as much oftener as the chairman of the committee may demand.

System Is Satisfactory

The committee system has been in operation for several months and up to the present is giving excellent satisfaction. Many advantages have accrued including broader consideration of factory matters, elimination of any personal favor

that might possibly arise in the purchasing department, rapid determination of a balanced stock by the purchasing committee which thus permits placing purchase specifications for exact requirements when needed and avoids overstocking of material, increased and improved production, and economy.

The co-operation of the heads of departments working together in committee, thus effecting co-ordination of effort, is believed, by the company, to have produced maximum results with a minimum degree of labor.

Care has been taken not to destroy any of the good effects to be secured by decisions which are the result of careful study and analysis of the members of the different committees by a rule which forbids any employee of the company except the president or assistant general manager to change or cancel any decisions as rendered by a committee without first consulting the chairman of that committee. If in his opinion the change is of minor importance and not sufficiently of consequence to require a committee meeting he may authorize the change over his signature. Or if the suggested change is for betterment and is important he may submit it at once to the committee, as for example if a road engineer should attempt to change the design of any spring after the design has been approved by the engineering committee, he must first consult the chairman of that committee.

Final Salary Decision

No department head is allowed to promise or file application for an increase in salary without first consulting the chairman of the salary committee. And as an added assurance to the perfect operation of the system, and in order to place the responsibility for its conduct upon an individual, the chairman of the executive committee, the assistant general manager of the company, is given the veto power and final decision in all matters.

Thermoid Disk Coupling Replaces Steel

THE recent growth in popularity of fabric couplings immediately suggests the question as to why this material should be more satisfactory than steel. It will permit of a slight disalignment of the running parts, it is true, but so will a steel disk coupling, and yet steel has been replaced by the fabric in more than one instance.

A case in point occurred at the Mercer plant during the spring of 1914, when the present model 22-70 was being developed. E. H. Delling, who was at that time chief engineer of the Mercer company, was developing the experimental chassis. Originally the car was fitted with a large diameter flexible leather coupling between the clutch and the gearset, taking up all the play between the engine shaft and the main shaft of the gearbox.

Changes in the gear in the gearbox and the propeller shaft brake which was added necessitated a different type of joint in place of the leather. The leather had to be abandoned, as it was found that with the stresses that were added with the propeller shaft brake, it would not be strong enough in the small diameter that was required.

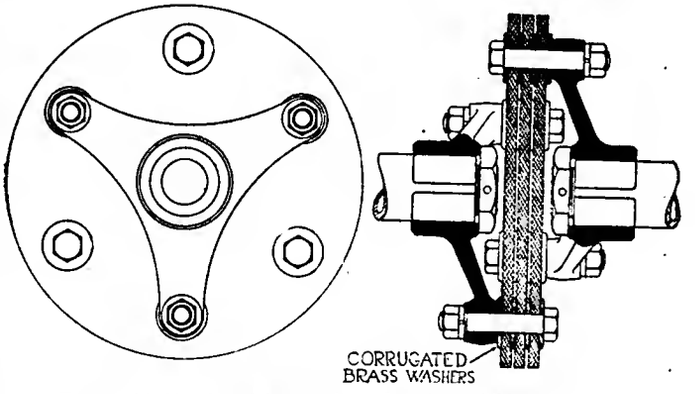
The three leather disks were replaced by two thin leaves of tempered saw steel on six or eight cars as an experiment. It was known that the strength of these leaves would be ample, but the uncertain part of the coupling was its action in practice and very soon after they were put on it developed that a rattle would occur. It took several days to locate this, as nobody suspected the coupling which was solidly bolted together. What made it particularly puzzling was the fact that the rattle would occur generally on direct drive and especially when running light or coasting. There was one peculiar feature and that is the rattle would never occur until the car had been run for 10 or 15 min.

The steel disks in the coupling were finally suspected, and to determine if they were really at fault they were removed and a fabric disk coupling made by the Thermoid Rubber Co. was substituted. Immediately the rattle ceased, and as a result of these experiments all the Mercer 1915 as well as the 1916 and 1917 cars were equipped with the Thermoid Hardy disks.

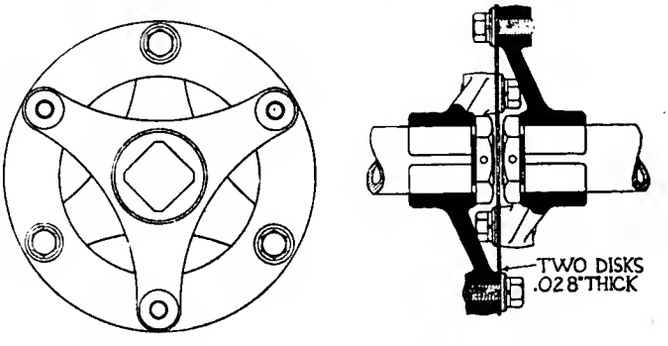
The laminated steel disk coupling which had to be abandoned is shown in the accompanying drawing. A three-armed dog is used on each shaft as a flange member and so arranged that the flange arms are bolted alternately between the arms of the flange on the opposite shaft. The flange members are secured to the shafts by squared ends and bolts which fit upon the ends of the shafts.

An investigation into what could have caused the noise in a coupling of this nature showed that it was due to a slight misalignment between the crankshaft and the mainshaft of the gearbox. This would cause a flexure in and out of the disks, similar to the action of a hand in pressing the bottom of an oil can, or in the disk devices that are used as a diaphragm in noise-making instruments. This in turn would transmit a torsional vibration to the gearset pinion whose teeth would naturally vibrate against the teeth of the countershaft gear, the clearance between the teeth being 0.004 in. The rattle would not show up for the first 10 or 15 min. until the grease would soften and cease to act as a cushion. After a little running the grease would thin out and thereafter the noise would be heard.

The Thermoid Hardy disks which replaced those of saw-steel are made under a patented process, of cross layers of high grade cotton fabric with rubber between them, and they are cured under compression similar to a tire. Their tensile strength is very high and is higher than that of leather as tests at the Columbia University have shown that couplings of the design illustrated which were worked out by E. H. Delling have withstood a torque of 21,000 inch-pounds before fracture.



Thermoid Hardy disk coupling for driveshaft mounting



Saw-steel disk coupling which was found to rattle

The Rostrum

Door Spring as Aid in Assembling

EDITOR THE AUTOMOBILE:—A few years ago when automobiles were built with the cylinders cast separately, it was not much trouble for two men to replace the cylinders after removing them. Now we have cylinders cast in blocks of from two to six and also piston rings with two and three parts, making it almost impossible for two men to assemble a motor, unless in an up-to-date shop, with all of the latest tools at hand.

For the benefit of those who have experienced trouble in entering the piston rings in a block of cylinders, where two or more pistons are entering at once, the best helper is a ⅜-in. screen door spring. Cut the spring into lengths, which, when stretched tight around the piston, will ride down with the cylinder, driving the rings into place without any trouble. The springs can be easily removed and used over, as soon as they have served their purpose on each piston.

Trenton, N. J. F. F. PALMER.

Data on Mean Effective Pressure

Editor THE AUTOMOBILE:—What is the brake mean effective pressure or the mean effective pressure of an internal combustion engine?

2—How can this be determined?

3—What is the pressure on the latest cars?

Orange, Cal. A. W.

—At the instant of explosion the pressure is very high and falls as the piston descends. The mean effective pressure is the average of the pressure existing throughout the firing stroke. Since a certain amount of power is used up within the engine and by friction the actual power delivered at the flywheel is less than it would be if figures from knowledge of what the mean effective pressure really is. We therefore take the mean effective pressure and multiply it by a decimal representing the percentage efficiency of the engine. Thus if the actual mean effective pressure is 100 and the mechanical efficiency 75 then the brake mean effective pressure would be 75 lb. per. sq. in. In actual engines this brake mean effective pressure varies between 60 and 100 lb.

2—When a horsepower test has been made the actual power delivered at a stated number of revolutions is none. We know this power comes from so many strokes of the pistons and of the impulse of the explosions. Knowing the area of the piston head and the length of the stroke we therefore know the brake mean effective pressure.

3—Answered under 1.

Troubled by Axle Shafts Breaking

Editor THE AUTOMOBILE:—I have a 30-hp. car with a semi-floating rear axle; the axle shafts are 1 5/16 in. diameter and at outer ends run in roller bearings which have a hardened steel sleeve 1¾ in. outside diameter, 1 5/16 plus bore which slips over the axle shaft and forms a bearing or inner race for the rollers.

The axle shafts frequently break off short at inner end of outer bearing and to remedy this I intend to have vanadium steel shafts made 1¾ in. diameter, dispense with the inner race of bearing and let the axle shaft run on the rollers. The rollers are of the high duty type and only about 2 in. long, so it is probable that the rollers would cut the shaft bad enough in a few thousand miles to require the replacement of the shaft.

Will it be safe and proper to case-harden the outer end of the axle shaft? I intend to do this by heating the outer end of the axle red hot in a bath of melted cyanide. Do you know of a better method? How long should the axle be left in the cyanide bath?

Should the axle be plunged in water after taking out of the cyanide?

My car is a 1913 Reo and it is easy to make the change in size of axle shaft without any large changes in the axle housing.

Carthage, Mo. F. B. N.

—You should have no difficulty in repairing the axle in the way you suggest. It would probably be unwise, however, to attempt to harden the vanadium steel shaft by the method you mention as this will almost certainly make the end very brittle. You do not say whether you are equipped for accurate heat treatment. Suppose you used a 0.3 or 0.4 carbon chrome vanadium steel, this should be quenched at 1650 deg. Fahr. and drawn at 850 deg. Fahr. The shaft should be gradually tapered from the back of the bearing down to the place where it fits in the differential hub. A somewhat easier heat treatment perhaps would be available if you used 3½ per cent nickel steel of a 0.3 to 0.35 carbon, allowing this to cool slowly after forging, heating then to 1550 deg. Fahr., quenched in order to reheat to about 650 deg. Fahr., allowing it to cool slowly in the air after this last heating.

Wiring Diagram of Wagner System

Editor THE AUTOMOBILE:—Kindly give wiring diagram of Wagner 12-volt starting and lighting system on 1913 Moon 48 roadster.

Wilmington, N. C. R. W. M.

—Wiring diagram of Wagner 12-volt starting and lighting system used on 1913 Moon is illustrated in Fig. 1.

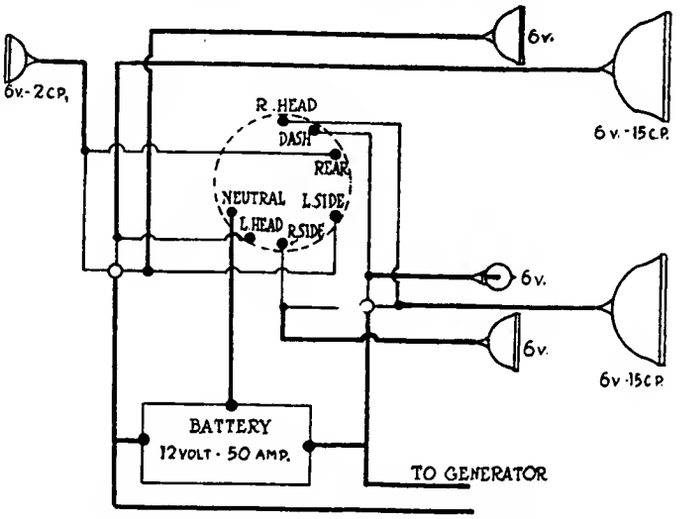


Fig. 1—Wiring diagram of Wagner 12-volt starting and lighting system on 1913 Moon 48 roadster

Empire 1-Ton Axle Has No Differential

The new 1-ton worm-driven axle made by the Empire Axle Co., Dunkirk, N. Y. It is characterized by the fact that it has no differential and is the first stock axle to be so offered on the market in this country. The housing is of the three-piece type, following previous Empire practice. The central part of the housing carries the worm and wheel as a complete unit

Central Part of Three-piece Housing on New Truck Type Carries Worm—Brake Shafts Oiled from Inside

NO differential is fitted in the new 1-ton worm-driven truck axle just brought out by the Empire Axle Co., Dunkirk, N. Y. This is the outstanding feature of the new axle, which was designed primarily for use by trucks of 1-ton capacity to sell at less than $1,000 and for converting passenger-car chassis into trucks of 1-ton burden. It is the only stock worm-driven axle so far to be placed on the market in which the almost universally adopted differential has been eliminated.

Advantages claimed for the use of a solid axle without a differential are that better traction is obtained over snow and bad roads, less tendency toward skidding when the brakes are applied, greater tire mileage and an appreciable reduction in the weight of the axle assembly itself.

The elimination of the differential enables a live axle to be used which is sufficiently strong to carry the weight and take the drive. This means that the casing for the worm gear need only be strong enough to support the driving stresses without any weight-carrying function. The elimination of the differential and the resultant decrease in the weight of the necessary housing makes the new axle light and simple.

The axle is designed to take both the propulsion and the torque through the springs, and is provided with a three-piece housing which follows previous Empire design. The center housing carries the worm and the worm wheel as a complete unit.

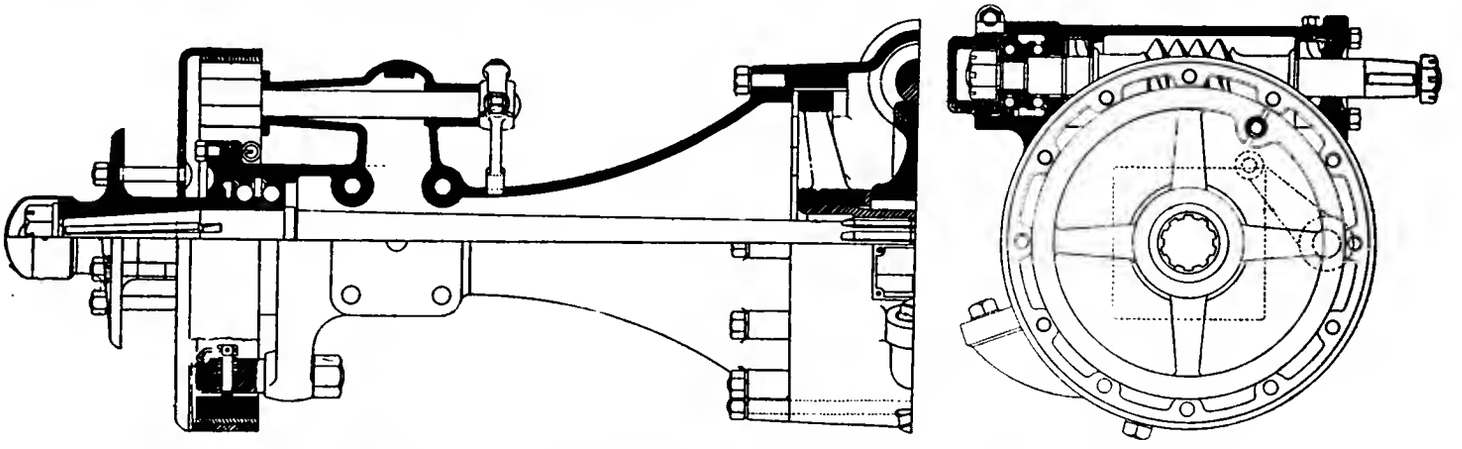
As shown in the sectional view, the complete housing is open from end to end and is characterized by a new construction in which the brakeshaft bracket is hollow and in open communication with the interior of the remainder of the housing, thus insuring the brakeshafts a sufficient quantity of oil for lubrication.

The worm and worm wheel are of the straight type. The worm is of 3½ per cent nickel steel, case-hardened and then ground to the correct tooth form. The worm wheel is cast from special phosphor bronze of high tensile strength. It is cut by the hobbing process, thus producing a generated tooth.

The driveshafts are of chrome nickel steel, heat-treated and ground to size. They are of the three-quarter floating type and are supported at the wheel ends on double-row radial-and-thrust type ball bearings, as is shown in the left of the section. As shown at the right of the section, the worm thrust is taken by double heavy-duty ball thrust bearings and the radial loads by two roller bearings of the Hyatt type.

The brakes are internal-expanding, with drums 13½ in. in diameter and 2¼ in. wide. The spring pads, which are integral with the side housings, are cubical in shape and hollow, forming the open interior connection between the housing proper and the brakeshaft supports. The spring centers are 38 in. apart, and are designed for springs 2½ in. wide.

The tread of the axle is 56 in. and the ratio between the worm and the worm wheel is 7.2 to 1. The axle is designed for a rated load of 3550 lb. on the tires, including chassis, body and live load.



Longitudinal half section and section through the worm carrier of the new Empire 1-ton axle which has no differential and which is designed for use on trucks of that capacity to sell at less than $1,000. Note that the spring pads are cubical and hollow, and that the brake shafts are lubricated from within the housing through the open communicating passage formed by the hollow spring pads. Also note the straight worm and how it is carried on thrust ball bearings and straight roller bearings for the radial load. The axle is of the three-fourths floating type, mounted on double-row radial-and-thrust type ball bearings at the wheel ends

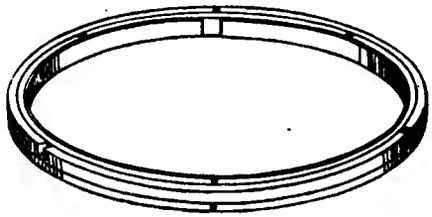
ACCESSORIES

Big 4 Tire

SEVERAL radical departures from conventional tire construction embodied in the Big 4 include construction in three parts, any one of which may be replaced if damaged, unusually low air pressure required and, according to the manufacturer, positive puncture-proof and well-nigh trouble-proof qualities. The tire consists of two side walls and a non-skid tread rim, an idea of the construction in which these units are assembled being given in the accompanying illustration. With this tire it is necessary to carry only spare side walls and tubes instead of complete spare tires. The tread rim is claimed to be exceedingly durable and the replacement of the tread or one or both of the side walls is much less expensive than to buy a new tire. Only 25 lb. pressure is required for a 34 by 4-in. size, as compared with 80 lb. for an ordinary tire of these dimensions.

The company also manufactures tires for truck use which are claimed to give the same high resiliency as the ordinary pneumatic tire and also the uninterrupted service and durability as the solid type. A non-skid tread rim is also made for winter service on the truck tires. —Big 4 Tire and Rubber Co., Cleveland, Ohio.

Section through Big 4 tire, showing the two side walls and the tread rim



Chopa compound piston ring

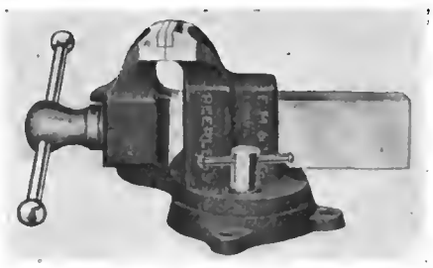
Chopa Piston Ring

This is a compound gray iron piston ring made of several sections overlapping in a manner said to prevent leakage. Because of the compound construction an even pressure is exerted on the cylinder walls and the ring will accommodate itself to worn pistons, it is claimed. Price, each, 3¾ in. diameter or under, $1; 4¾ in. and under, $1.25; 5¾ in. and under, $1.50.—Chopa Piston Ring Co., 264 East Jefferson Avenue, Detroit.

Pillsbury Hubpul

This is a combination hubcap, wheel puller and a device for pulling the car out of mud holes. It is made exclusively for Ford and Model 490 Chevrolet cars. The hub pull is quickly attached to each rear wheel of either of the cars above mentioned by simply unscrewing the original hubcap and inserting the device in its place. It may be left on permanently if desired, and, as it is neatly designed and nickel-plated, does not detract from the car's appearance.

The rubber-covered special hooks which attach to a rope are hooked around the spokes the rope wrapped once around the hub, then carried forward or backward from the underside and anchored to a stake, telephone pole, tree, post or any stationary object; the motor is then started and the wheels slipping causes the cable to be wound, which pulls the car gradually out with much greater leverage than could be obtained with the motor on ordinary traction. The device may also be used for removing wheels from the rear axle without stripping threads. The price per set is $6.—Pillsbury Mfg. Co., Minneapolis, Minn.



Fulton Peerless machinists' vise

Fulton Machinists' Vise

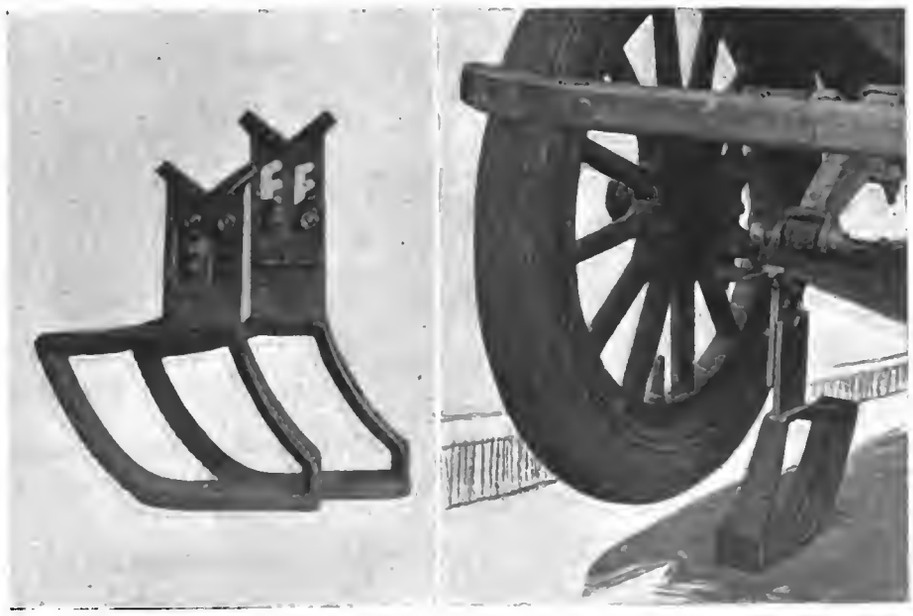
This light weight swivel base vise is suitable for the repair shop. The jaws are cast steel welded onto the face of the vise, giving a very strong construction. The vise may be swiveled to any desired position and firmly locked by a taper head bolt. Price, No. 295, with 3-in. jaws, $7.50; No. 31, with 4-in. jaws, $10.50.—Fulton Machine & Vise Co., Lowville, N. Y.

Rotary Jack

As shown in the illustration, this jack is inserted under the axle and the car driven ahead slightly so that the axle and wheel are automatically lifted up on the jack which is built on the rotary lever principle. The device is composed of two main parts together with an adjustable pillar for axles of different heights. The jack is made of malleable iron and weighs 7 lb. It sells for $2.50. —Rotary Jack Mfg. Co., 340 Moore Building, San Antonio, Tex.

Waynelight Headlight Regulator

The Waynelight is a small transformer designed to steady the headlight illumination of Ford cars. The current passes from the magneto through the trans-



Left—Two views of the Rotary jack, showing upper and lower extreme adjustments. Right—Rotary jack in use under a car axle

former to the lamps, which are wired in multiple. Such wiring prevents the possibility of both lamps going out, as is the case with the usual series winding. It is claimed that the transformer furnishes a steady light at all speeds above 10 m.p.h. The installation is simple, it being only necessary to substitute 6-volt lamps in place of 9-volt lamps, attach the present headlight wire to one of the magneto terminals of the transformer, and ground the other transformer terminal to the frame. A pair of wires, each connected to a lamp, extend to the two lamp terminals of the transformer. The Waynelight may be placed on the dash, under the hood or floorboards, or wherever it is most convenient. Price, $3.65.—General Electric Co., Fort Wayne, Ind.

Spotlight Push Switch

This push-button switch placed in the neck of the spotlight permits the hand that directs the rays to also control the current. Two buttons project from the switch—one black and one white. Pressure on the white button causes the lamp to light, if out; the black button is used to shut the lamp off. The switch is insulated by means of a fiber sleeve, and the push-buttons are put in place in the switch after it has been placed in the small neck of the lamp.—Cutler-Hammer Mfg. Co., Milwaukee, Wis.

Compound Air Compressor

Air is taken into the large cylinder of this twin-cylinder air-cooled air compressor and compressed to about 50 lb. per square inch; at this pressure, and at about one-quarter of its original volume, it is delivered to the small or high-pressure cylinder, which compresses it to its final pressure. This system is claimed to give higher efficiency, to require less power and to reduce the wear on the parts. Belt drive is used, either from a general power line or directly from a motor. In this last case the motor is mounted on four uprights at the top of the compressor, making a very compact arrangement. Complete installations, including steel air-storage tanks of any capacity, are handled.—United Engine & Mfg. Co., Hanover, Pa.

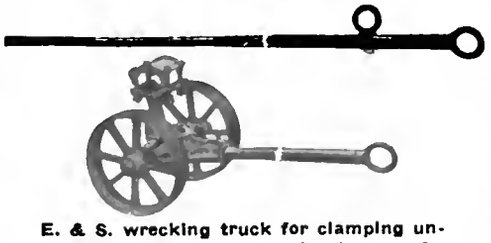
Badger two-piece spring bumper

Waynelite transformer for Ford headlights

Compound twin-cylinder air compressor



E. & S. wrecking truck for clamping underneath the axle of a disabled car for the purpose of towing

Utility Luggage Lock

Luggage may be locked to the robe-rail or foot-rest with this lock. Two steel fingers may be closed together and locked, securing the articles to the car. For example, gloves or coats may be clamped to the steering wheel, a suitcase may be locked to the foot-rest or the control levers may be fastened to the steering-wheel quadrant, thus preventing the theft of the car. Two keys are supplied with each lock. Price, $1.—Backus Novelty Co., Smetheport, Pa.

Badger Spring Bumper

The Badger two-piece spring steel bumper is designed for indestructibility and may be fitted to almost any car. The cross-bar is made of high quality spring steel specially tempered, though very resilent to cushion a shock, is sufficiently stiff to protect the parts. The bar may be adjusted to any angle desired. Price, $12 with 2-in. nickel bar; $10.50 with black bar.—Auto Parts Mfg. Co., Chicago, Ill.

E. & S. Towing Truck

This is a wrecking truck that may be clamped beneath the axle, thus supporting the car and permitting it to be towed in. Two 14-in. wheels with an 18-in. tread are mounted on a malleable iron frame that has an adjustable upright clamp that may be bolted to the axle. Two towing poles are included, one 10 ft. long for a rear axle break, and one 5 ft. long for front axles. All bearings have grease cups and the total weight is 160 lb. Price, $27.50.—Ellis-Smith Mfg. Co., Buffalo, N. Y.

Edison Lamp Assortment

A display box of assorted sizes of Edison Mazda lamps has been brought out to aid dealers in their sales work. The assortment is the minimum stock which any dealer should carry and will enable him to meet the lamp requirements of 90 per cent of all the gasoline and electric cars for 1914, 1915 and 1916. The lamps are arranged in an attractive container and a list of the lamps carried is printed on the cover of the container.—Edison Lamp Works of General Electric Co., Harrison, N. J.

Industrial Miscellany

Factory

Jenkins Machine Co., Sheboygan, Wis., has been purchased from W. W. and Louis Wolff by A. G. Studeman, formerly an executive of the Falls Machine Co., Sheboygan Falls, Wis., and Mark Hoeper, until now assistant treasurer and purchasing agent of the J. I. Case Plow Co., Racine, Wis. The Jenkins company is capitalized at $70,000 and will not change its name or capital for the present.

Osborne Casting Co., Racine, Wis., recently organized, expects to take occupancy of its new 15-ton gray iron foundry on Jan. 1.

Burnell Fuel Saver Co., Milwaukee, Wis., has been organized by A. A. Giese and A. J. Melms to manufacture carburetion auxiliaries and similar appliances for the automobile trade. The capital stock is $10,000.

Nu-Way Puncture Cure Co., capital stock $20,000, has been organized in Green Bay, Wis., to manufacture a fibrous compound for automatically sealing punctures. R. C. Moore is the inventor. Offices have been opened at 403 West Walnut Street, Green Bay.

Four-Wheel Drive Auto Co., Clintonville, Wis., is spending approximately $20,000 in new tools and equipment for additions now being completed. It has a standing order for twenty trucks per week for an indefinite period, and is now producing four a day. By Jan. 1 the output is to be six a day.

Commercial Body Co., Trenton, N. J., manufacturer of bodies for automobiles, has acquired property at 809 South Broad Street for an addition to its plant.

Perfection Tire Co. will commence work soon on the erection of a plant at Niagara Falls, Ont., for the manufacture of tires and rubber goods.

Packard Motor Car Co. has acquired additional property in Long Island City, adjoining its present plant, on which it will erect an eight-story building, more than doubling its present facilities.

International Rubber Co., South Bend, Ind., maker of automobile tires, is pushing the erection of its new plant in this city. The building will be completed by Dec. 12. Half of the brickwork on the building, which will be 382 by 80 ft., is already done. The building with its equipment involves an expenditure of about $200,000. The plant is located on the Vandalia tracks and Edwin Boulevard, in the southern part of the city. The company has established 1500 selling branches.

H. W. Kardell, president of the Kardell Motor Car Co., plans to build a factory in Alton, Mo., to build a motor plow.

Simplex Automobile Co., New Brunswick, N. J., has opened the Simplex Recreation League. The old Middlesex Club house in Highland Park has been transformed into club quarters for its employees. The league was organized by the directors of the company for the benefit of the men who are employed at the plant and their families.

McCord Mfg. Co., Wyandotte, Mich., will build an addition.

R. H. Reynolds & Co., New Albany, Ind., is erecting an automobile woodstock plant, combining two factories now at Corydon and De Pauw, Ind.

Personal

J. K. Stewart, of the Stewart-Warner Speedometer Corp., Chicago, Ill., has purchased 2½ acres of ground on Jackson Avenue, Long Island City.

M. D. Randall heads the Randall Motors Corp., New York City, to handle the wholesale and retail distribution of the Grant.

G. F. Blake has been appointed district sales manager of the Auburn Ignition Mfg. Co., Auburn, N. Y., maker of the A. I. M. Auburn and Blazer spark plugs and valve lifters.

H. H. Cobe and **C. F. Coe** have joined the Burd High Compression Ring Co., Rockford, Ill., organization in Boston, Mass. Mr. Cobe has been in the automobile field since 1903, being connected with the Haynes, Locomobile, Jackson, Palmer Singer and G. & H. Carbureter Co.

W. J. McKechnie has been appointed general manager of the American Forging & Socket Co., Pontiac, Mich. He was for 4 years chief accountant of the Rutenber Motor Co., Marion, Ind. The American Forging & Socket Co. makes forgings and bow sockets for automobile makers.

C. E. Collard, formerly Philadelphia branch manager of the Chase Motor Truck Co., and C. N. Gillette, Southern division sales manager in the same organization, have both severed their connections with that company to become associated with the Selden Truck Sales Co., Rochester, N. Y. Mr. Collard becomes division sales manager in the Philadelphia territory, while Mr. Gillette assumes the same position in the Southern terri-

tory, with headquarters at Charlotte, N. C.

J. F. Hill, who has been manager of the Splitdorf Service & Sales Co. branch at Kansas City, Mo., for the past 4 years, recently resigned his position and will open a garage business at Waterville, Me. His successor as manager at Kansas City is O. J. O'Donnell, recently with the Chicago office of the same company.

Newell Lyon, for 3 years general sales manager of New York State for the White Co., has been made manager of the Kansas City branch of the company, recently established after purchase of the Kansas City White Co. from J. H. Toole. Mr. Toole is now taking a vacation and his future plans are not announced, although he may be connected with the branch.

N. L. Le Blond, formerly secretary and general manager of the Hannibal Motor, Wagon & Body Co., Hannibal, Mo., has been made Western manager of the Dearborn Motor Truck Co. and will make his headquarters at Kansas City. Augustine Gilmore, formerly of Chicago, succeeds Mr. Le Blond in the Hannibal company as general manager, Miss Hattie Salee being made secretary.

A. D. Plughoff has resigned as vice-president and general manager of the Willys-Overland Co. of California and as vice-president of the Overland-Pacific, Inc. He is leaving San Francisco immediately for an extended trip through the Eastern factories before announcing his future plans. He has been connected with the automobile trade for 18 years, having been associated with J. W. Leavitt when he handled the Overland on the Pacific Coast.

W. L. Burgess, St. Louis, manager of the tire and tube department for the Dorris Motor Car Co., has resigned to become sales manager for the Sterns Tire & Tube Co., that city.

W. F. Kneip, manager of the Franklin Motor Car Co., Baltimore, Md., has been elected president of the Baltimore Automobile Dealers' Assn. C. H. Reeves, Jr., of the Foss-Hughes Co., was elected vice-president, and E. S. Bliven, of the Standard Motor Co., secretary and treasurer.

E. T. Backus, who came to Baltimore, Md., on Aug. 1 and assumed charge of the headquarters of the Ford Motor Co. in this city, has been appointed one of the three assistants to N. A. Hawkins, general sales manager of the Ford company, with headquarters at Detroit. Mr. Backus was in charge of the Ford branches in Dallas and Houston, Tex., before coming there. A. A. Grisham, assistant manager here, succeeds Mr. Backus as manager of the Baltimore headquarters. K. G. Harig, a Baltimorean, who was in charge of the State wholesale department, becomes assistant manager. H. W. Ford will be the successor in Mr. Harig's old place.

H. O. Foskitt has been placed in charge of the Jackson Motor Co. branch at Lawrence, Mass.

W. R. Dudley, St. Louis, manager of the Vesta Battery & Equipment Co., has been transferred to the Chicago branch as a traveler, and is succeeded by F. G. Fulkerson, formerly of Cleveland.

F. E. Miles has become purchasing agent of the Lewis Motor Corp., Detroit, Mich. Mr. Miles was formerly connected with The National Motor Vehicle Co.

Z. B. Leonard has resigned his position with The Perfection Spring Co., Cleveland, Ohio. He was formerly head of the laboratory.

Floyd Robinson of 251 Putnam Avenue, Detroit, advertising manager of the Regal Motor Car Co., Detroit, Mich., was seriously injured recently when he was struck by a motorcycle. His skull was fractured. Later reports are that Mr. Robinson's condition is much improved.

E. J. Warren, formerly general manager and treasurer of the Crosby Co., Bangor, Me., will open in January his new store, the Auto Supply & Rubber Co., on Post Office Square, with a full line of automobile accessories and rubber goods.

Dealers

Fisk Rubber Co., Philadelphia, has arranged to lease a four-story building which will shortly be erected at 664-66 North Broad Street at a cost of $100,000.

Henry A. Rowan, Jr., Co., 2036 Sansom Street, Philadelphia, has taken over the agency for the Smith Form-a-Truck.

Ramey Motors Co., Philadelphia agent for the Hal, has moved into its new showroom at Broad and Brown Streets.

Garwood Motor Car Co., 2248-52 Euclid Avenue, Cleveland, Ohio, has been organized to distribute the Pathfinder in northern Ohio.

J. R. Flannery, Jr., formerly of Stillman & Hoag, has entered into partnership with Wm. C. Brightly, Englewood, N. J., to conduct a garage and general machine shop under the name of Brightly & Flannery, Inc.

Standard-Racine Rubber Co., Oneida and Jefferson Streets, Milwaukee, distributer of Racine tires and a general line of accessories, will build a new tire and accessory store at Astor Street and Juneau Avenue, on a corner site measuring 175 by 135 ft. The present quarters will be continued as a general accessory and supply house.

Jesse A. Smith Auto Co., 215 Wisconsin Street, Milwaukee, State distributer of Hudson cars since 1911, has taken a long-term lease on the Welch garage building, Grand Avenue and Seventh Street, which has just been vacated by Harry Newman, Inc., former Chalmers distributer. It is one of the largest buildings in Milwaukee devoted exclusively to automobile distribution, being four stories high and containing nearly 50,000 sq. ft. of floor space.

Weber Implement & Automobile Co., St. Louis, Mo., has taken the Maxwell agency and the Brinkmann Motor Car Co. has withdrawn from business, its affairs being liquidated. Coincident with this, G. C. Brinkmann, former president of the Brinkmann Motor Car Co., filed a voluntary petition in bankruptcy in which his liabilities were given as $32,198 and his assets at $87, of which $5 was cash.

Aniser Mfg. Co., St. Joseph, Mo., has changed its name to the Mechanical Belt Co. and is now marketing the Crowe fan belts exclusively. This product will be sold through the jobber.

Willys-Overland Co. has opened a show and sales room at 71 Broadway, Yonkers, N. Y.

Motor Car Sales Co., Bloomington, Ill., has broken ground for a new garage. This structure will be located at 406-410 West Washington Street. The company will utilize the building as a sales agency for the Chalmers and Dodge.

J. W. Leigh Motors Co., St. Louis, has leased space in the Plaza Hotel building at 3302-3304 Locust Street as headquarters for the Apperson.

Paul Crawford, Birmingham, Ala., State agent for the Chandler, has opened his new salesroom at 406 Twenty-first Street.

Spangler-Tubbs Motor Co., Boston, has been formed to handle the Metz.

Stockyards Garage, Denver, is the name of a new business opened at East Forty-seventh Avenue and Lafayette Street to deal in accessories. The manager is A. J. Mosley.

Rocky Mountain Auto Sales Co., a new concern at 204 Sixteenth Street, distributer of Auburn cars and Gladiator tires for Colorado, Wyoming and part of Nebraska and South Dakota, has added the Regal distributing agency for Colorado and half of Wyoming.

Roberts Auto Co., Denver, Marmon distributer for Colorado and Wyoming, has moved from 220 Sixteenth Street into a new $20,000 building at 1231-1239 Broadway.

George H. Estabrook, Denver, is now the business name for the Briscoe and Hollier distributing agency for Colorado and Wyoming, formerly conducted as the Briscoe Auto Sales Co., of which Mr. Estabrook was president. The location is still 1646 Broadway.

Mulford Bros., Streator, Ill., have opened the old Halladay garage, corner of Kent and North Sterling Streets, and will carry on a general business in the repairing of automobiles and sale of supplies.

Tioga Automobile Co., Philadelphia Hupmobile dealer, has sold out to a firm headed by Robert McCormick, who was formerly in charge of sales for Hurley & Early, this city. The new company is looking around for larger quarters, and is at present located at 332 North Broad Street.

Richwine-Haines Co., Philadelphia, has leased the showroom at 719 North Broad Street, where it will handle the Liberty car. The territory includes Pennsylvania, New Jersey, Delaware and Maryland.

The Thomas-Bonner Co., accessories, electrical goods, etc., 152 Sixth Street, Milwaukee, has been released from bankruptcy litigation instituted in September. Creditors have caused the action to be dismissed and the business will be continued without interruption.

E. E. Williams and Clarence Heiderscheid, proprietors of the Kingdom Garage in Hardin, Ill., dissolved partnership, the former purchasing the interest of the latter. Mr. Heiderscheid remains in Hardin and will devote his time to the Ford car agency and service station. He has let the contract for a new garage and sales agency on Main Street.

Garber & Habecker, Washington, Ill., have dissolved partnership. The former will continue the garage and sales agency, while Mr. Habecker will occupy the W. H. Long building and will open a garage and sales agency of his own. Mr. Garber will continue to handle the Ford car, while the other lines previously handled by the firm will now be in charge of Habecker.

Moerschell Electric & Auto Supply Co., St. Louis, announced that H. E. Q. Kuhn, factory expert on Rayfield carbureters, has joined that company to handle Rayfield business.

VOL. XXXV NEW YORK—THURSDAY, NOVEMBER 16, 1916—CHICAGO NO. 20

G. M. C. Earnings Break Record

Approximately $25,000,000 Cash on Hand—Buick Builds 400 Cars Daily

DETROIT, MICH., Nov. 15—October earnings of the General Motors Co. were the largest in its history, the treasurer reporting approximately $25,000,000 cash on hand. The Buick Motor Co., its largest subsidiary, is turning out 400 cars daily.

—

Cole Price Raised $100

DETROIT, MICH., Nov. 13—The Cole Motor Car Co. will raise the price of its eight-cylinder car $100, to $1,685, on the touring and roadster models. This change will go into effect Jan. 1.

—

Kissel To Raise Prices Dec. 1

HARTFORD, Wis., Nov. 13—The Kissel Motor Car Co., this city, will raise the prices of its Hundred Point Six models on Dec. 1.

—

Leonard Leaves Perfection Spring

CLEVELAND, OHIO, Nov. 15—Z. B. Leonard has resigned as chief of the laboratory of the Perfection Spring Co.

—

Belden Overland Chief Engineer

TOLEDO, OHIO, Nov. 10—Edward H. Belden has been appointed chief engineer of the Willys-Overland Co. this city. For the past 2 years Mr. Belden has been consulting engineer of the Packard Motor Car Co., Detroit.

Mr. Belden, who was born in 1868 at Jackson, Mich., began his business career as mechanical engineer with the McCormick Harvester Co., later becoming electrical engineer of the Fort Wayne Electric Co. and subsequently holding the same position with the Westinghouse Electric & Mfg. Co. Mr. Belden has been designing automobiles since 1905. In 1913 he was president and engineer of the Belden Engineering Co. and in 1914 became connected with the Packard Motor Car Co. He built one of the first six-cylinder motors constructed in this country and has been a member of the Society of Automobile Engineers since 1913.

—

Smith Form-A-Truck Co. Sold

CHICAGO, ILL., Nov. 15—The Smith Form-A-Truck Co., this city, maker of a motor truck unit that can be attached to the chassis of a low-priced car, has been acquired by Michaelis & Co. and affiliated interests. It is stated that the demand for the product is ahead of the present output, which will be immediately increased and additional buildings will be at once arranged for. The total sales for this year will reach approximately $3,000,000 and the net earnings will amount to at least $1,000,000.

—

Steenstrup with General Motors Export

DETROIT, MICH., Nov. 14—Peter S. Steenstrup has joined the General Motors Export Co., succeeding O. G. Bennett, who has resigned to embark in a new venture for himself. Mr. Steenstrup was formerly the general foreign representative for the Hupp Motor Car Co. and spent the past 3 years abroad studying conditions in South America and in Europe.

—

Abbott to Build in Cleveland

CLEVELAND, OHIO, Nov. 9—The Abbott Corp. has applied for a building permit to construct a $110,000 plant at 1131 East 152d Street, covering a ground space of 110 by 681 ft.

10,000 Regals Planned for 1917

Co. to Concentrate on De Luxe Eight and J. Models—To Discontinue Others

DETROIT, MICH., Nov. 15—The Regal Motor Car Co. production department is planning on an output of 10,000 cars for the 1917 season. The company will concentrate on model J and the De Luxe eight-cylinder type, dropping all other models. Enlarging the 1917 output to 10,000 cars represents almost 100 per cent increase over the production for the 1916 manufacturing season.

—

Humphrey Now in Detroit

DETROIT, MICH., Nov. 14—S. H. Humphrey, who resigned as vice-president in charge of production with the Chalmers company to become the vice-president in charge of manufacturing for the Briscoe Motor Corp., has resigned the latter position and returned to Detroit to engage in business for himself.

—

Whitman National Production Engineer

DETROIT, MICH., Nov. 14—F. H. Whitman has been appointed production engineer for the National Motor Vehicle Co. at Indianapolis. Mr. Whitman was formerly connected with Dodge Bros.

—

International Truck Incorporated

ALBANY, N. Y., Nov. 9—The International Motor Truck Corp., as a result of the recent refinancing, has been formed and will carry on business with $7,372,790. The capital consists of 71,043 shares of $100 each and 53,638 shares of no par value. The directors are A. E. Moore, G. F. Jebbitt, T. S. Buckingham.

Cummins-Monitor Reorganized

Monitor Motor Car Co. Formed—$1,000,000 Capital Planned for Near Future

COLUMBUS, OHIO, Nov. 11—A complete reorganization of the Cummins-Monitor Co., this city, makers of Monitors has been effected by the incorporation of the Monitor Motor Car Co. with a preliminary capital of $10,000. This capital will be increased to $1,000,000 in the near future, a large part of which will be paid in. The concern has been assembling and manufacturing two models for the past year and these models will be continued with slight changes. They are the four-cylinder, priced at $795, and the six-cylinder, priced at $995.

Under the reorganization C. C. Cummins will be president, H. P. Jeffers, vice-president and F. S. Cummins, secretary and general manager. The plant is located at 402 Mount Vernon Avenue, where it will remain for the time being. It is the plan to manufacture several thousand cars during the coming season and to strengthen the sales organization by securing agents in all of the larger distributing centers.

The Monitor is the result of the work of the Cummins brothers, who were formerly agents in Columbus. They conceived the Monitor several years ago and have been manufacturing a number of the cars.

—

R. J. Firestone Now Vice-President

AKRON, OHIO, Nov. 9—At the annual meeting of the Firestone Tire & Rubber Co., Nov. 2 R. J. Firestone was elected vice-president. Mr. Firestone has been sales manager for a number of years.

A. G. Partridge, formerly assistant sales manager, was appointed to succeed Mr. Firestone as general sales manager.

F. C. Blanchard becomes manufacturers' sales manager in charge of the company's increasing business among automobile makers.

—

Braender, of Tire Co., Dies

RUTHERFORD, N. J., Nov. 9—Philip Braender, president of the Braender Rubber and Tire Co., this city, died on Nov. 4 at his home in White Plains in his 68th year.

Mr. Braender was born in Germany in 1849 and at the age of 16 came to America where he entered the real estate and building business in New York City.

In 1911 he entered the rubber business in conjunction with the late Frank McGowan under the style name of Cable Pneumatic Tire Co. and later in 1912 took over this interest under the present name and associated with him was the late G. Strauss, formerly with the Goodyear Rubber Co. in the bicycle tire time.

Mr. Braender was also president of the Braender Building & Construction Co. of New York, a member of the Arion Society of New York and Teutonia Lodge, No. 617, F. & A. M. He leaves a widow and four sons.

—

VerLinden Elected Olds President

LANSING, MICH., Nov. 13—E. VerLinden, general manager of the Olds Motor Works, has been elected president of that concern. Announcement of VerLinden's election came after a recent meeting of the board of directors of the Olds Motor Works.

VerLinden's early training in production methods was gained with the American Radiator Co. Before joining the Olds organization in 1912, he was a production expert for the Buick company as manager of Plant No. 1.

Prior to his connection with Buick, VerLinden was in business for himself, under the corporate title of the Michigan Auto Parts Co., which was bought by the General Motors Co. in 1909.

—

Laciar Is Kent General Sales Manager—Stock Being Underwritten

NEW YORK CITY, Nov. 13—R. J. Laciar has been appointed general sales manager of the recently formed Kent Motors Corp. Mr. Laciar made his entry into the automobile field in 1903, at which time he joined the late Capt. La Roche in the marketing of the Darracq car. Later he spent several years popularizing the two-cylinder Buick through the East. He has since been connected with W. E. Metzger in the sale of the E. M. F. car, with the Hupp company as Eastern district manager, and later with W. C. Durant in the Chevrolet organization.

The company, which will build a plant in Bellville, N. J., has a capital consisting of 200,000 shares of the par value of $10 each. Sixty per cent, or 120,000 shares, is held in the treasury. Against this will be issued negotiable trust certificates exchangeable in 3 years for stock.

The Security Transfer and Registrar Co., 66 Broadway, this city, has been designated as the depository and transfer agent of the company. The stock has been underwritten and is to be listed, it is stated, on the New York Curb market.

—

McCulla in Overland Engineering Dept.

DETROIT, Nov. 12—William R. McCulla has joined the engineering forces of the Willys-Overland Co. Mr. McCulla was formerly the aircraft motor engineer for the Packard Motor Car Co.

New Plant for Saxon Co.

To Build on 40-Acre Plot—First Unit of 500,000 Sq. Ft. Floorspace

DETROIT, MICH., Nov. 12—The Saxon Motor Car Corp. is commencing the erection of a new plant on 40 acres of land recently purchased by them. The first unit will be 240 by 1262 ft. and will have 500,000 sq. ft. of floorspace, and will house several departments so grouped that a car will move steadily forward from one end of the building to the other for assembly construction.

Progressive manufacturing and assembling will be employed in every department possible. Incoming material will be moved by traveling cranes and elevators to the stockrooms, and a system of conveyors is planned by which stock will be carried to the different manufacturing departments. The first unit will be completed May 1, and the remainder of the buildings June 1, 1917.

—

Empire Tire To Be Refinanced

TRENTON, N. J., Nov. 14—Increased business and expansion has forced one more company to join the long list of those to be refinanced this year. The Empire Rubber & Tire Co., this city, has about completed negotiations for reorganization and refinancing. The details of the plans of refinancing will be announced in the near future as soon as completed. At present the plans for the underwriting of the new stock are being worked out by Andrews & Co., New York. General C. E. Murray will continue as the active head of the company.

The Empire company was organized in 1913 with a capital stock of $500,000 common and $500,000 7 per cent cumulative preferred, with $500,000 common and $428,720 preferred outstanding.

—

Hammers Is Hackett Consulting Engineer

DETROIT, MICH., Nov. 11—M. J. Hammers has been retained as consulting engineer for the Hackett Motor Car Co., and has been appointed as a non-resident director of the company.

—

Lascaris Re-elected Salon Head

NEW YORK CITY, Nov. 13—At its recent meeting the Automobile Salon, Inc., which will conduct the Automobile Salon on Jan. 2 to 10 at the Astor, this city, re-elected Emanuel Lascaris president and T. E. Adams vice-president. Robert Schuette was elected secretary-treasurer, succeeding the late Stefan Kjeldsen, and J. R. Eustis was appointed manager of the salon.

N. A. C. C. Opposes Scare Ads.

Eighty Members Go on Record as Against It—Committee for Improvement

NEW YORK CITY, Nov. 13—With the object of eliminating what it terms "scare" advertising, eighty members of the National Automobile Chamber of Commerce at its last meeting recorded themselves as being opposed to advertising which can be classed under this head. This opposition is directed against not only concerns connected with the automobile industry, but against advertising in general which can be characterized under the scare heading.

Exactly what is meant by scare advertising might be made clear from the following extract bearing on the subject. "We may expect to see pictures of people dying in restaurants because they ate the wrong brand of bacon; of people mangled at the bottom of elevator shafts because they rode in an elevator using the wrong safety device; of children being rescued from fires because the wrong kind of window panes were used in the building; of passengers being carried under the ocean waves because they traveled on the wrong steamship line," etc., etc.

The N. A. C. C. has at present a committee working for a betterment of advertising along this line. This committee is expected to accomplish as much as possible by co-operation not only with vehicle makers, but also with those manufacturing parts and accessories. The question of scare advertising has already been taken up with certain companies, and it is expected that there will be an elimination of such as the result of this work.

The reason for the N. A. C. C. taking up this matter is that members of the chamber hold the view that scare copy is negative rather than affirmative in its effect, and that some more positive and constructive form of advertising could be used.

—

A. O. Smith Corp. Incorporated

ALBANY, N. Y., Nov. 14—The A. O. Smith Corp., as a result of the recent refinancing, has been incorporated in this state with 130,000 shares, of which 100,000 shares are without par value. It will carry on business with $3,500,000. The directors are L. H. Gunther, S. B. Howard and A. W. Britton.

—

Dodge Suit Against Ford Postponed

DETROIT, Nov. 15—A continuance of 1 week, by consent of opposing counsel, was granted in the injunction proceedings started by Dodge Bros. to restrain Henry Ford from extending the Ford plant and to compel a further distribution of profits to Ford stockholders.

"The preliminary taking of evidence will not be finished in the coming week," said Attorney E. G. Stevenson for Dodge Bros., "but we expect it will have reached a point where we can come into court and agree upon the fixing of the day certain for the commencement of the trial."

The plaintiffs state that they expect to present evidence to show that the expansion planned by the Ford head jeopardizes the monetary interests of the minority stockholders.

$200,000,000 Offered

Henry Ford on the witness stand today admitted the offer of $200,000,000 was recently made to him for his 58 per cent of the shares of Ford stock. This offer he rejected and stated that his company made $3,600,000 in August and September, 1916, following the price decrease.

—

Lozier Bros. Co. Formed—$10,000,000 Capital

CLEVELAND, Nov. 14—Harry A. Lozier, former president of the Lozier Motor Car Co., and who recently retired as president of the H. A. Lozier Co., this city, has launched a new company, the Lozier Bros. Co., capitalized at $10,000,000. New York and Philadelphia capital is stated to be behind the company. Only 25 per cent of the capital is to be issued at present, the balance being reserved for subsequent disposal in expanding the business. The incorporators are F. R. Hansell of Philadelphia and G. H. B. Martin and S. C. Zymour of Camden, N. J.

—

S. R. B. Creditors Ask for Sale

PHILADELPHIA, PA., Nov. 9—A committee consisting of 95 per cent of the creditors of the Standard Roller Bearing Co., which went into the hands of a receiver in 1913, has asked the Federal Court for an order to sell the property to pay the creditors. The sale has been objected to by some stockholders, who maintain that only the disposal of merchandise is necessary to meet all claims. Judge Thompson has decided to permit counsel to get together and draw a decree providing for a sale that will satisfy all claims and submit it to the court for approval.

—

Burgess Resigns from Dorris

ST. LOUIS, MO., Nov. 9—W. L. Burgess, has resigned as sales manager of the Dorris Motor Car Co., St. Louis, and is now manager of sales of the Efficiency Oil Corp., St. Louis.

Bankers in Control of Hess-Bright

Vanderlip One of Group — Conrad Patent Control Remains with Hess-Bright

PHILADELPHIA, PA., Nov. 14—The Hess-Bright Mfg. Co., manufacturer of ball bearings in this city makes the following statement with regard to the purchase of controlling interests in its company by a group of financial men who also own a substantial interest in the S. K. F. Ball Bearing Co., Hartford, Conn. The company states that controlling interest in the shares of the Hess-Bright Mfg. Co. has been secured by a group of bankers including Frank A. Vanderlip, National City Bank, New York, and Phillip W. Henry, Thatcher M. Brown, and Franklyn B. Kirkbride, of New York, and Marcus Wallenberg of Stockholm, Sweden.

The Hess-Bright company and the S. K. F. company will be operated quite independently of each other. The manufacturing facilities of Hess-Bright will be increased materially. B. D. Gray, recently elected president, retains his former stock holdings and will continue to manage the business as president. F. E. Bright, one of the organizers of the company, has retired from active participation but remains as chairman of the board of directors. The remainder of the organization continues as heretofore, excepting the board of directors, which follows:

Chairman of board, F. E. Bright; President, B. D. Gray; Willard Parker Butler, New York; Arthur V. Morton, Philadelphia; Paul von Gontard, managing director of the Deutsche Waffen- und Munitions Fabriken, Berlin, Germany.

Last week THE AUTOMOBILE mentioned that control of the Conrad patent royalties would pass from the Hess-Bright Co. This is not the case, as complete control of the Conrad patents will continue with the Hess-Bright Mfg. Co. as heretofore.

—

Edwards Joins Automatic Carbureter

CHICAGO, Nov. 14—F. E. Edwards of Chicago, one of the most widely known men in American motor-racing circles, has joined the Automatic Carbureter Co., Chicago, as efficiency engineer. His chief work at present will be the introduction of the new Church fuel feed. Edwards has been chairman of the technical committee of the American Automobile Assn. and its chief technical representative for a number of years, and has supervised the majority of the speed and economy tests during that time.

Winther Motor Truck Co. Formed

Capital to Be $330,000—Factory to Be Built at Kenosha in Spring

KENOSHA, WIS., Nov. 11—M. P. Winther, who has been prominent in the development of the Jeffery Quad and for many years was associated with the Thomas B. Jeffery Co., Kenosha, has organized the Winther Motor Truck Co., with an authorized capital stock of $330,000, and is making final arrangements for the construction and equipment of a large factory in this city. A tract of 4 acres just west of Kenosha was purchased yesterday, and it is hoped that by the middle of April work on buildings will have progressed sufficiently to make production possible. Further details concerning the personnel of the Winther organization, the extent of its shops, and the product, are not available at this time, but will be made public in due time.

—

Watts Joins Republic Rubber

YOUNGSTOWN, OHIO, Nov. 9—L. A. Watts has been appointed purchasing agent of the Republic Rubber Co., this city. Other changes include the addition of James Buckley, who succeeds Neal Mahan as general foreman of the pneumatic tire and tube departments. Harry Davenport will be succeeded as foreman of the truck tire department by Thomas Wilson.

—

Eaton Torbensen Axle Manager

CLEVELAND, Nov. 13—J. O. Eaton, treasurer of the Torbensen Axle Co., Cleveland, was elected general manager of the company at a directors' meeting held recently.

—

Dudley Federal Truck Advertising Mgr.

DETROIT, Nov. 12—L. B. Dudley has been made the advertising manager of the Federal Motor Truck Co. He succeeds G. W. Cushing, who recently resigned to join the advertising staff of the Hudson Motor Car Co. Mr. Dudley was formerly connected with the Campbell-Ewald Co., advertising agent.

—

New Acme Truck Worm Axle

DETROIT, MICH., Nov. 10—The Acme Motor Truck Co., this city, is now producing a worm-driven truck axle incorporating, as its principal feature, the M. & S. worm differential. Another feature of the axle is that the brakes, of special design, have a full contact for the entire circumference excepting the small space occupied by the actuating cams.

It is built in a size for 2½- or 3-ton trucks, the standard reduction for this size being 7¾ to 1. The axle is a one-piece steel casting, with the worm gear carried in a separate carrier secured by eight bolts and having the small worm housing and axle bowl cover integral with it. The axle is of the semi-floating type, running on ball bearings throughout. The worm is of the straight type.

—

Glide to Make Its Own Motors

PEORIA, ILL., Nov. 13—In line with the general policy of the Bartholomew Co., maker of the Glide car, to concentrate the manufacture of its entire car in its local plant, is the announcement of a large addition to its plant for the purpose of building its own engines. The company is at present using a stock motor.

—

National Carbon to Add

CLEVELAND, OHIO, Nov. 13—The National Carbon Co., this city, maker of batteries, will soon erect new factory buildings costing $1,000,000. The company has just bought a parcel of land across Berea Road from the present carbon plant. This 63 1-3-acre tract has a frontage of 3368 ft.

—

Cornell Is Cole Asst. Sales Mgr.

INDIANAPOLIS, IND., Nov. 11—F. A. Cornell, formerly in charge of Willys-Overland service department and since then in charge of the heater department of the Perfection Spring Co., has been made assistant sales manager of the Cole Motor Car Co., in charge of the service department.

—

Graves Joins Russel Axle

DETROIT, MICH., Nov. 11—H. S. Graves has been appointed sales engineer of the Russel Motor Axle Co., North Detroit, Mich. Mr. Graves was formerly connected with the General Motors Co. as engineer. He has been connected with the automobile industry for the past 11 years.

—

Baker Resigns from G. V.

BOSTON, MASS., Nov. 13—Day Baker has resigned from the electric vehicle business of the General Vehicle Co. in New England.

—

Wiltrout Joins Crow-Elkhart

ELKHART, IND., Nov. 13—R. S. Wiltrout has been made efficiency manager of the Crow-Elkhart Motor Co., Elkhart, Ind. He was formerly with the Stewart-Warner Speedometer Corp. and recently has been manager for the John W. Blackledge Mfg. Co.

Papers for S. A. E. Meeting

Aeroplane and Farm Tractor Engines Will Be Covered—Many Others Promised

NEW YORK CITY, Nov. 13—The technical papers to be presented at the 1-day professional session on Jan. 11 of the Winter Meeting of the Society of Automobile Engineers will be representative of the enlarged activities of the society. Some of the papers will relate to automobile engineering, but in addition subjects of interest to aeroplane, tractor and marine engineers will be presented. The papers committee, of which K. W. Zimmerschied is chairman, is making the arrangements.

Captain V. E. Clark, U. S. A., will present a paper an aeroplanes with special relation to engines. This paper will deal also with the expcriences of the army aviators on the Mexican border and suggest improvements in construction. It is also hoped that a detailed description will be given of a foreign aeroplane engine, which has recently been produced commercially in this country. A well-known engineer will discuss the design of engines for farm tractors. A paper will probably be read on motor trucks, with reference particularly to the proposed military specifications now being considered by the truck standards division of the S. A. E. standards committee and a specially appointed board of the War Department.

Tentative plans have been made to have experts contribute papers on passenger car spring-suspension, electrical equipment of gasoline cars, high-speed automobile engines, dynamics of the automobile and crankshaft balancing. It will thus be seen that the papers arc of sufficient variety to attract every member of the Society. The authors will give brief digests of their papers, thus allowing time for lengthy and adequate discussion of the more important ones.

—

S. A. E. Dinner and Theater Party Tickets Scarce

NEW YORK CITY, Nov. 16—That the annual banquet of the Society of Automobile Engineers on Jan. 11 at the Hotel Biltmore will be a banner one in point of attendance is assured by the fact that to date 460 tickets have been sold. The capacity is 750.

Every seat, numbering 762 has been taken for the special performance of Ziegfeld's Midnight Follies, which comes as a climax to the dinner. The demand for these seats has been so large that thirty applications so far have been returned.

Toledo Plants Are Rushed

Factories Breaking All Production Records and Financial Outlook Is Promising

TOLEDO, OHIO, Nov. 13—Toledo automobile and parts makers are rushed to capacity. Each company is building or planning to care for increased demand. The chief difficulties of the plants are lack of skilled workmen and insufficient space. Everywhere the companies tell of remarkable prosperity and an extremely good financial future outlook.

The Electric Auto-Lite Co. has enjoyed a great expansion. The company employs 2200 people and occupies 422,000 sq. ft. of floorspace, and has four buildings in the plant, including a new one recently finished and utilized. One structure is used for heavy machine work and assembly, a second for stock rooms, receiving and shipping, mail order and repair work, and on one floor has 500 girls engaged in winding field coils and armatures. A third building is occupied as a factory for making lamps, horns and starting switches, and the fourth serves as the office, drafting and experimental structure. The new building is four-stories high and constructed entirely of steel, glass and brick.

The concern did $6,000,000 business in 1915 and to date has shipped $10,000,000 worth for 1916, manufacturing 1400 starters a day now as compared with 800 in the year preceding. Numerous mechanical improvements have been installed to increase facilities for production, and include electric ovens, cable conveyors, twenty automatic machines, automatic punch presses, milling machines and eighty Potter & Johnson machines.

Milburn's Big Increase

At the Milburn Wagon Works 900 men are employed, as compared to 600 men at the same time in 1915. The company is making 1500 cars this year as against 1000 in 1915. It has purchased the plant of the Toledo Bending Co. and converted it into plant No. 2 of the Milburn factories, adding 128,732 sq. ft. to the 514,931 sq. ft. already occupied. It is planned to use plant No. 1 for the manufacture of closed cars and bodies, and plant No. 2 for making custom-made bodies and to care for light delivery business.

The concern has recently developed the electric taxicab business and plans to engage in that particular branch of the industry with special effort. Body work has increased 100 per cent, and from present indications will grow an additional 100 per cent during the coming year.

The Ohio Electric Vehicle Co. states that October was one of the most successful months in the company's career. Business for the year has increased more than 100 per cent. The concern manufactured 650 cars to date in 1916, as compared with 300 cars in 1915, and have doubled the number of salesmen on the road, doubled their national advertising and increased the number of men employed by 40 per cent. At present they employ 250 men, but would take on 300 men if they could find the skilled aluminum workers they require. From present prospects they anticipate an increase of 1000 per cent in business for the coming year.

—

Haynes to Add 600,000 Sq. Ft.

KOKOMO, IND., Nov. 13—The board of directors of the Haynes Automobile Co. last week authorized A. G. Sieberling, general manager, to prepare plans for a new building and to buy machinery for a capacity of 100 cars daily. It was announced that contracts will be let for buildings which will have a capacity of three times the number of cars made at present. The new buildings will have about 600,000 sq. ft. of floor space, which will be added to 350,000 sq. ft. now in operation in the company's plant.

—

Standard Tractor to Move

ST. PAUL, Nov. 11—The Standard Tractor Co., St. Paul and Wilimar, Minn., will move to the old prison at Stillwater, Minn. The company has $500,000 capital. It makes tractor engine plows and other farm machinery.

—

Briscoe Plants for K. C. and S. F.

SAN FRANCISCO, CAL., Nov. 11—The Briscoe Motor Corp., Detroit, Mich., has completed plans to build an assembling plant in this city and Kansas City, Mo. The local plant will be capable of turning out from 10,000 to 20,000 cars a season. The Kansas City plant will cost $300,000.

—

More Room for Mayo-Skinner

CHICAGO, Nov. 13—The Mayo-Skinner Mfg. Co. has moved into enlarged quarters at 2115 Elston avenue. The company will enlarge its line in the near future.

—

S. G. V. Creditors to Meet

READING, PA., Nov. 11—The creditors of the S. G. V. Co. of Delaware, which formerly operated its automobile plant here, will meet in the near future to distribute $85,000 in the hands of a receiver.

To Build Monarch in Hyattsville

Carter Brothers Co. Secures Exclusive Rights To Build Eight and Twelve

HYATTSVILLE, MD., Nov. 13—Monarch cars will be manufactured in this city as soon as all the machinery and materials arrive here. The Carter Brothers Co., this city, has secured the exclusive rights of the Monarch Motor Car Co., Detroit, and will build both Monarch models, an eight and a twelve.

In addition to the above standard models a new design of light car will be added to be known as the Monarch Midget.

The business of the Monarch company will be continued under the Monarch Motor Car Co., a subsidiary organization of the Carter Brothers Co.

—

Holihan Completes New Plant

DETROIT, Nov. 12—The Holihan Mfg. Co. has just completed its new plant on the 3½ acres of land they recently purchased. The main building is 80 by 400 ft. of the latest construction and includes steel and glass windows and a monitor roof. In addition a steel storage structure 65 by 45 ft., and a shipping shed 65 by 45 ft. with floors raised to car level are in process of completion.

The company has made ample allowance for future expansion and the present plant will cover about 50,000 sq. ft. of floor space.

At a special meeting of the stockholders, the capital stock was increased to $135,000, and the board of directors was increased by the election of H. J. Moir of Donaldson & Moir, and S. E. Ferris of H. W. Noble & Co.

—

Palmer-Moore To Quadruple Capacity

SYRACUSE, N. Y., Nov. 13—The Palmer-Moore Co. has increased its capital stock from $200,000 to $300,000. The additional capital will be used to quadruple the output of the plant, bringing the production up to above 600 trucks during the next year.

—

Elgin Motor Corp. to Add

CHICAGO, ILL., Nov. 13—The Elgin Motor Car Corp., this city will erect several additions to its factory to take care of increased business. This increased space will enable the company to build from 20,000 to 25,000 cars after the original year's allotment of 7500 is completed. Another building is now in process of construction and will permit the building of thirty cars a day.

Build Ams-Sterling at Amston

C. M. Ams Becomes President —Headquarters in Bridgeport —Car Design Improved

NEW YORK CITY, Nov. 13—Headquarters of the Sterling Automobile Mfg. Co., Inc., have been moved from this city to Bridgeport, Conn., Charles M. Ams having become president of the concern. Ams-Sterling cars will be built in a factory at Amston, Conn., in one chassis on which will be mounted roadster, five-passenger touring car and ½-ton delivery bodies.

Car at National Shows

The Sterling company will exhibit a car and a chassis at the national shows. Present specifications, which may be slightly changed later, differ from last year's model in several particulars, the general tendency being toward larger and better dimensions and equipment. Wheelbase has been lengthened from 102 to 110 in. The engine will continue as a four-cylinder L-head type, but will be 3⅛ by 4½ instead of 2⅞ by 4 in. This power plant has a removable head and its power output is 28 hp. at 2200 r.p.m. High efficiency and economy are the aims of its designers. Oiling is combination pump and splash with sight feed on cowlboard. Cooling continues thermo-syphon with a honeycomb radiator with polished German silver shell. Timing gears are helical and valves are large diameter with moderate lift.

A Stromberg model M carbureter replaces the make used last year and ignition is now by Bosch high-tension magneto instead of optional. Bosch starting and lighting is used with Willard 12-volt battery.

Dry-Plate Clutch Used

A Borg & Beck dry-plate clutch replaces the cone type previously used. The three-speed-and-reverse selective gearbox is continued. A semi-floating rear axle supplants the three-quarter design, and semi-elliptic springs replace cantilevers. Hotchkiss drive is continued. Control is still left, steering being of the irreversible split nut type, a 17-in. corrugated walnut wheel being used. Gasoline tank is in the cowl with filler cap and gage in the cowlboard. Tires are 30 by 3½, the same as last year. Wheels are hickory with twelve spokes and fitted with demountable rims.

Equipment includes two-piece windshield, double-bulb headlamps, tail and dash lights, Warner speedometer driven from the propeller shaft, one-man Jiffy top and dust boot, tools, etc.

Bodies are low, rakish streamline types with comfortable seats and plenty of leg-room. They are upholstered in black and painted Sterling blue black. Although price has not yet been definitely determined, it will probably be between $700 and $725.

Abbott Downing Trucks on Market

BOSTON, MASS., Nov. 11—The Abbott Downing Co., Concord, N. H., one of the pioneer wagon builders in this country, which recently entered the truck making field, has leased salesrooms in Boston at 84 Brookline Avenue, in charge of F. S. Davis. The company is making two trucks of 1 and 2-ton capacities that will sell at medium prices.

The company will give special attention to truck bodies because of its facilities at its big plant at Concord, N. H. It will continue in the wagon making business also. Until the building is fully completed on Brookline Avenue where its sales and service station will be conducted, Mr. Davis will make his headquarters at 394 Atlantic Avenue.

Canadian Chevrolet Sells 8000 Cars

OSHAWA, ONT., Nov. 11—The Chevrolet Motor Co. of Canada with headquarters at Oshawa, Ont., which has been manufacturing cars for a year, has sold 8000 cars to Canadians and has under course of construction large extensions to its present plant. Three new buildings are in course of construction which will give a total extra floorspace of 277,075 sq. ft. Part of this extra space will be used for storage and part for service but the larger part utilized in increasing its manufacturing facilities.

Wants to Represent Tire in S. A.

NEW YORK CITY, Nov. 13—Walter E. Haumann, manager in Buenos Aires for Prowodnik tires, made in Riga, Russia, is in this city looking for representation of some American tire in Argentina. Mr. Haumann was manager of the Prowodnik interests from the start of the Buenos Aires branch until it was closed due to war conditions a few months ago. Previous to his South American experience he spent 4 years in Portuguese East Africa in export and import work.

Fisher Body Sales Record

DETROIT, Nov. 14—A new high record was established by the Fisher Body Corp. in October when the sales amounted to $1,470,000, compared with $773,000 in October, 1915, an increase of 90.12 per cent. For the 8 months ended Oct. 31 last the sales increased 79.74 per cent.

Chicago Warehouse for Marathon Tire

CUYAHOGA FALLS, Ohio, Nov. 13—The Marathon Tire & Rubber Co. will open a warehouse in Chicago at 1458 South Michigan Avenue. It will be under the management of H. F. Smith.

Pilot's One-Model Program

Touring Car and Roadster at $1150 Each—Production To Be Doubled

RICHMOND, IND., Nov. 13—The Pilot Motor Car Co. of this city will confine its 1917 manufacturing efforts to a single car model known as 6-45, which will list as a touring car and roadster at $1150. The two models 6-55 and 6-75, which the concern has been manufacturing, have been discontinued. Increased production is to be carried out on the one model, and factory additions are now nearly completed, which should double the production of last year. In addition to the 6-45 being produced as a five-passenger car with a double cowl, it will also be built as a four-passenger roadster type with divided front seats and access to the rear seat via the space between the front ones.

In this one chassis the motor is a six-cylinder block type, 3⅛ by 5 with valves on one side. The cylinders are cast integrally with the upper half of the crankcase and the camshaft, water pump, and magneto shaft are driven by helical gears. Delco ignition, lighting and starting is used with the Bendix drive for the starting system. Other equipment includes Stewart vacuum gasoline system and Gould battery. The clutch is a dry-plate type, and the gearset, a unit with the motor, is a three-speed design with nickel steel gears. The tubular propeller shaft carries two inclosed universal joints. The floating axle uses spiral bevel reduction. Steering is irreversible worm and sector type. Cantilever rear springs are used.

The equipment includes a motor-driven horn, Stewart speedometer, one-man top, single tire carrier, and demountable rims.

Kerosene Motors Co. Formed

PEORIA, ILL., Nov. 9—The Kerosene Motors Co. with a capital of $100,000 has been formed in this city to manufacture kerosene motors and accessories. The organizers are George McFarland, president of the Peoria Tractor Co., E. M. Smith and F. H. Bush. The motor is similar to that used in the Peoria tractors. Manufacturing is expected to start in about 30 days, the company planning to make the entire new motor and its parts. The company recently made a test trip of 8000 miles.

King Tire Opens New Plant

DETROIT, Nov. 12—The King Tubeless Tire Co. will open its new plant at Barberton, Ohio, this week.

Brunswick M. C. Co. Formed

To Assemble Car Selling at $1,950—Capitalized at $500,000

NEWARK, N. J., Nov. 13—The Brunswick Motor Car Co. has been formed with a capitalization of $500,000 to produce an assembled automobile selling at $1,950, f.o.b. Newark. A four-cylinder Wisconsin engine, 4¾ by 5½, with a Rayfield carbureter is used. Other features are: Fedders radiator, Bosch magneto, Westinghouse starting and lighting, Brown-Lipe gearset, Timken axles and Parish & Bingham frame. It also uses Gemmer steering gear, Stewart vacuum feed and Silvertown cord tires. Drive is Hotchkiss type.

The body is of a high quality job, all rear compartment woodwork being of mahogany, as is the instrument board. There are also five mahogany cabinets in the rear compartment, containing a set of Thermos bottles, sandwich tins, and room for other articles. Each cabinet has a Yale lock. Two Waltham clocks are furnished, one on the instrument board and one in front of the rear compartment.

Russel Smith is president of the company, Everett Cadmus is vice-president, J. T. Bunt is secretary, and A. V. Weeks is treasurer. The company is temporarily using a plant of 15,000 sq. ft. floor-space, but a new plant will later be established along the Pennsylvania Railroad tracks outside of Newark. From 500 to 1000 cars will be produced during the coming year.

Aniser Becomes Mechanical Belt

ST. JOSEPH, MO., Nov. 13—The Aniser Mfg. Co. has changed its corporate name to Mechanical Belt Co. and is marketing Crowe fan belts exclusively. L. D. W. Van Vliet is president, other officers being, secretary and treasurer, H. D. Gilbert; sales manager, O. G. Young, Jr.; directors, J. D. Richardson, J. E. Dolman and the officers.

Firestone Gives $1,000,000 for Welfare

AKRON, OHIO, Nov. 13—The Firestone Tire & Rubber Co., this city, has voted to give $1,000,000 for an employees' welfare and insurance fund. Two weeks ago the company opened its new club house, said to have cost over $300,000.

$1,000,000 Plant for Victor

PHILADELPHIA, Nov. 14—The Victor Motor Co., this city, capitalized at $2,000,000, will build a $1,000,000 plant at Grubbs Landing, near Claymont, Del., for the manufacture of the Victor Four, a moderate-priced car. The company recently bought 12 acres of land there for building purposes. It has also leased a group of eight factory buildings at Jenkintown, and will commence operations there in a limited way. One thousand men will be given employment in the temporary plant. The employees in the whole plant will number 2000.

Iowa Companies Merge

FORT MADISON, IOWA, Nov. 13—At a special meeting the stockholders of the Perfection Tire & Rubber Co., Fort Madison, Iowa, it was voted unanimously to consolidate the Perfection Tire & Rubber Co., the Perfection Tire & Rubber Co., Ltd., and the Champion Auto & Equipment Co. About 130 stockholders and officers were in attendance.

Goldman to Build Trucks

CHICAGO, ILL., Nov. 13—Eugene Goldman, Chicago Republic truck dealer, is severing his connection with that company and has organized his own company to build trucks. Complete announcement and specifications will be given later.

Pullmore Motor Truck Co. Formed

NEW CASTLE, OHIO, Nov. 2—The Pullmore Motor Truck Co. has been organized in this city with a capital of $600,000, the concern having purchased a site on the Gibson farm, along the Butler Avenue Road.

Advertisement Errors

A typographical error appeared last week in the advertisement of the U. S. Ball Bearing Co. in THE AUTOMOBILE. The advertisement stated: "A leading manufacturer of worm gear units in England advised against the use of annular bearings to carry worm loads." This was in error. The copy should have read: "A leading manufacturer of worm gears in England advises against the use of roller bearings to carry worm loads and recommends the use of annular bearings to carry worm loads."

A clerical error in the advertisement of the Golden, Belknap & Swartz Co. appearing in THE AUTOMOBILE for Oct. 19 made it appear that the cylinders of the G. B. & S. engine have a bore of 3¾ in. and a stroke of 4¾ in. The dimensions should have been 3¾ in. bore and 4¼ in. stroke.

Fisher Body Buys Regal Unit

DETROIT, MICH., Nov. 13—The impression given in a story last week that the whole plant of the Regal Motor Car Co. was sold to the Fisher Body Co. was due to an error, as the Regal company sold only one of its units to that company.

$2,000,000 Plant for Cadillac

Co. Plans To Increase Working Force from Present 8000 to 12,000

DETROIT, MICH., Nov. 14—The Cadillac Motor Car Co. has purchased a 40-acre site formerly owned by the American Car & Foundry Co. and will erect a new factory for the construction of Cadillac cars. The projected plant, upon completion, will entail an investment in buildings and machinery of approximately $2,000,000. The company plans to employ about 12,000 men in the new factory. At present the company has 8000 employees.

Goodyear to Make Own Fabric

HARTFORD, CONN., Nov. 11—The Goodyear Cotton Mills, of Killingly, Conn., has been incorporated with $5,000,000 capital, to engage in general textile manufacturing. The incorporators are Francis Seiberling, Fred Miller and Harold Hutchins. This concern is practically a subsidiary of the Goodyear Tire & Rubber Co., Akron, and will manufacture tire fabrics for that concern.

Erickson Building Front-Drive Truck

WARREN, PA., Nov. 11—C. A. Erickson, formerly with the Scripps-Booth Co., Detroit, Mich., has arrived in this city and is perfecting two models of a front-drive delivery truck in the plant of the Jacobson Machine Mfg. Co. The light delivery truck which Mr. Erickson is bringing out will carry from 1000 to 1500 lb.

Harroun to Complete Factory by Spring

DETROIT, MICH., Nov. 11—The Harroun Motor Corp. is hastening every detail in the endeavor to complete their new factory by the early spring of 1917, so that next May will witness the new structure, with 300,000 sq. ft. of floor space, complete and ready to produce 2000 motor cars a month.

To Make Borland Wheel

ST. PAUL, Nov. 11—A company is to be incorporated to make the J. A. Borland wheel with solid rubber tire invented by Borland, recently of Cincinnati. Hadley Summers is to be president and E. C. Piersal, Dodge Center, Minn., is to be treasurer. R. M. Lampman is secretary and C. F. Updike vice-president under present plans.

Youngstown Co. to Add

YOUNGSTOWN, OHIO, Nov. 9—Plant extensions that will involve an expenditure of about $4,000,000 will be made by the Youngstown Sheet & Tube Co., this city.

Grossman Reincorporates

Forms Corporation with $320,000 Capital All Paid in To Take Care of Expansion

NEW YORK CITY, Nov. 13—The Emil Grossman Mfg. Corp. with a capital of $320,000 has been formed as the result of a reorganization of the company, which is part of the management's plan for the enlargement of the business. The activities of the company will be concentrated on the production of Red Head spark plugs, Ever Good bumpers and Ever Good mirrors. The manufacturing facilities in the Bush Terminal No. 20, will be enlarged. The company has leased building No. 95, Bush Terminal, for the exclusive rust proofing process which will be applied to all metal goods. The producing capacity in the grinding, polishing, nickel-plating and black enameling departments will be trebled.

The capital stock is divided into $150,000 first preferred; $160,000 second preferred; and $10,000 shares of common stock of no par value. The entire capital has been paid in. The capital of the old company consisted of $250,000 common and $100,000 preferred. This was all bought back by Emil Grossman, president and general manager.

—

O'Connor Back from Australia

DETROIT, MICH., Nov. 14—N. E. O'Connor of the service department of the Maxwell Motor Co. has returned to Detroit following a 3-months' trip in Australia and New Zealand.

—

M. & A. M. Adds Six Members

NEW YORK CITY, Nov. 13—The Motor and Accessory Manufacturers has added six new concerns to membership, bringing the total membership of the association to 260. Those admitted are: Walker Mfg. Co., Racine, Wis., accessories; Becker Brothers, Chicago, Ill., brushes for starting motors, lighting generators and magnetos. Bay State Pump Co., Boston, Mass., engine driven tire pumps and piston packings. Universal Motor Products Co., Indianapolis, Ind., tops. Ericsson Mfg. Co., Buffalo, N. Y., ignition apparatus, Berling magnetos. Craftsman Motor Corp., Chicago, Ill., detachable wire wheels and heaters.

—

Dazey Joins Chalmers Co.

DETROIT, MICH., Nov. 14—Roy Dazey has joined the Chalmers Motor Co. to take charge of the department that publishes the various house organs. Mr. Dazey was formerly connected with the Packard Motor Car Co. in the sales department.

—

Wilson Tire Reorganization Planned

SPRINGFIELD, ILL., Nov. 10—A reorganization of the Wilson Tire and Rubber Co., this city, is now in process. W. W. Gardner, treasurer of the company, has resigned and it is stated that E. W. Wilson, president and chief promoter of the company, will be succeeded by a new president at the next meeting of the board of directors.

—

Increased Capitals

NEW YORK CITY, Nov. 10—Brewster & Co., Long Island City, has increased its capital from $2,000,000 to $2,500,000 to provide funds for the manufacture of a chassis for its automobiles, formerly imported from England and France.

SPRINGFIELD, OHIO, Nov. 11—The Kelly-Springfield Motor Truck Co.; increase of capital from $3,014,000 to $6,000,000.

CLEVELAND, OHIO, Nov. 11—The Hall Motor Car Co.; increase of capital from $1,000,000 to $2,000,000.

DAYTON, OHIO, Nov. 13—The Acme Carbureter & Mfg. Co.; increase of capital from $10,000 to $15,000.

Copper at 33 Cents Per Lb.

Highest It Has Been Since 1864—Steel Expected To Go Up

NEW YORK CITY, Nov. 13—Copper featured this week's market activities with a rise of 3 cents a lb. to 33 cents. Tin rose $1.50 per 100 lb. to $43.87½. Fish oil rose 2 cents a gal. and lard oil 5 cents a gal. Linseed oil rose 6 cents a gal. to 96.

The enormous demand for copper is not yet satisfied and sellers predict 35 cents a lb. A glance over the price range since 1860 shows the high range that copper has reached. In 1860 this metal sold high at 24 cents a lb., and in 1864 reached 55 cents, the highest that has ever been paid for it. In 1894 it dropped as low as 9 cents a lb., the lowest price ever paid. Last year this time it sold as low as 13 cents and as high as 24 cents.

Though no increase took place this week in the steel market there is an upward tendency seen in quotations. The greatest activity since the present movement in the steel trade started is now here. Prices are showing increasing signs of moving toward even higher levels, despite the sharp advances already made. Foreign countries are inquiring for the metal, and domestic consumers also are taking whatever quantities the manufacturers are willing to book.

The market for crude rubber, particularly fine Para, is firm. Owing to an unusual drouth in the upper Amazon districts it has been impossible to get the crop down to Para and Manaos in normal amounts. Quotations are now 82 cents a lb. as against 73 a month ago.

—

Leak-Proof Business

ST. LOUIS, MO., Nov. 13—L. A. Safford, vice-president of the McQuay-Norris Mfg. Co., maker of Leak-Proof piston rings, says that business reports made at the meeting of the company's salesmen last week indicate a greatly increased business for the coming year. The reports, especially from Texas and the South, were the best ever received and indicated that the jobbers in that territory were set for their greatest year's business in 1917.

—

Longuet Buys Accessories for S. A.

NEW YORK CITY, Nov. 8—C. Longuet of the firm of Longuet & Co., Buenos Aires, Argentina, is spending some time in U. S. A. making purchases of automobile accessory lines for Argentina.

Mr. Longuet is making a rather complete study of various accessories that should be suitable for his field. He is taking the careful course of submitting samples to his firm before placing orders. In this way he is making certain that the lines of accessories are suitable. Two years ago Mr. Longuet spent some months in this country making purchases of automobile accessories and hardware merchandise.

—

Offer to Standard Welding Shareholders

CLEVELAND, Nov. 12—Shareholders of the Standard Welding Co. have received an offer from Borton & Borton, investment bankers, to purchase the property of the company at a price that will net them between $244 and $245 a share. The assent of 90 per cent of the total outstanding stock is necessary to transact the deal.

—

Dividends Declared

Maxwell Motor Co.; quarterly of 2½ per cent on common, payable Jan. 2 to stock of record Dec. 11.

Texas Co., regular quarterly 2½ per cent, payable Jan. 1.

Pratt & Whitney Co.; quarterly of 1½ per cent on preferred, payable Nov. 15.

—

Holmes Resigns from Michigan Welding

DETROIT, MICH., Nov. 15—A. L. Holmes has resigned from the sales department of the Michigan Electric Welding Co., effective Dec. 1.

Big Drop in Car Securities

General Motors Leads with 300 Point Loss—Maxwell, Chevrolet and Overland Drop

NEW YORK CITY, Nov. 13—Liquidation of automobile issues had the usual effect upon prices. Drops of from a fraction to 300 occurred. The recession, however, has not been taken seriously by automobile shareholders. October and November are generally poor months for automobile shares. With the approach of the automobile show, it is stated, motor shares will get stronger.

The most pronounced declines were shown in Chevrolet, Maxwell, Studebaker, Willys-Overland, and General Motors. The latter company featured the recession with a drop of 300 points from 810 to 510. Notwithstanding the depressing conditions of the market, there were several outstanding gains made by several of the stocks. Ajax Rubber, in face of the usual declines, has made an advance of 8⅝ points in 14 days. The company's stock within the last 2 weeks has sold as high as 77. White stock has also shown strength.

—

M. & A. M. Show Week Schedule

NEW YORK CITY, Nov. 13—The Motor and Accessory Manufacturers announces the following events scheduled for show week, Jan. 7, as follows: Wednesday, Jan. 10, executive committee, banquet committee, finance committee, and board of directors' meetings at association's offices; thirteenth annual meeting at Waldorf Astoria at 3 o'clock, followed by the ninth annual banquet at Waldorf at 7.30 p. m.; Thursday, board of directors meeting at association's offices.

—

Pierce-Arrow Assets $13,776,911

NEW YORK CITY, Nov. 11—The total net assets of the Pierce-Arrow Motor Car Co., which were taken over by the Pierce-Arrow Motor Car Corp., Buffalo, last week, were on Oct. 1 valued at $13,776,911. It is estimated that by Dec. 31, 1916, this value will have increased $1,000,000. For the 7 months ended July 31 last net profits before depreciation were $1,660,000 for August $540,000; September, $560,000, making a total of $2,760,000 for the 9 months, which after depreciation show a net profit of $2,460,000.

—

White Stock on 8 Per Cent Basis

CLEVELAND, OHIO, Nov. 11—The White Motor Co. has declared a quarterly dividend of 2 per cent, $1 a share, placing the stock on an 8 per cent per annum basis. The stock has been on a 7 per cent per annum basis. The dividend is payable Dec. 31 to holders of record Dec. 15. The par value of the shares is $50.

Traffic Laws to Be Clear

To Affect All Vehicles and Will Be Uniform in All States —Registration Included

WASHINGTON, D. C., Nov. 18—Simplification is to be the keynote of the new uniform motor vehicle and traffic law which will be promulgated in a short time by the legislative board of the A. A. A. The motor vehicle laws now on the statute books of most of the States are unnecessarily long and cumbersome. Duplication and further confusion exists where a State has separate motor vehicle and traffic laws on its books.

"Highway traffic in its final analysis is but a single problem," says Chairman O. I. Yellott, "whether it relates to motor cars, horse-drawn vehicles, traction engines, or pedestrians. Traffic should be handled as one problem by one general set of laws, so that the rules governing one particular kind of traffic may fit into and be consistent with those governing all other kinds of traffic.

"The details of the uniform law to be framed by the A. A. A. board have not yet been fully worked out, but it may be stated in a general way that the first sub-division will deal with general provisions relating to the applicability of the law and definitions of terms used therein. The second sub-division will deal with the appointment, powers, and duties of a State traffic commissioner, who will have general supervision of traffic of all kinds on the public highways. The third sub-division will deal with the registration of motor vehicles and operators. The fourth will deal with the operation of vehicles of all kinds on the public highways, as well as with the conduct of pedestrians thereon. The fifth will deal with the enforcement of the preceding provisions.

"Thus each sub-division of the proposed law will be almost wholly self-contained, thereby doing away with a great deal of the confusion which now exists in so many State laws by reason of different kinds of provisions being intermingled. But the idea of simplification will be carried still further. The provisions relating to the traffic commissioner will be made quite brief and very simple. One section will define his duties; another, his powers; both in like general terms. Broad provisions will be used to extend these duties and powers as far as may be necessary to accomplish the general objects of his appointment. The courts, as a rule, may safely be trusted to amplify provisions of this kind with much more satisfactory results than where the law-maker himself attempts to enumerate all such duties and powers in great detail."

—

Earle & Boggs Enlarge Accounts

NEW YORK, Nov. 14—Earle & Boggs, this city, manufacturers' representatives, will add to its account the Buda Co., Harvey, Ill., and the Fuller & Sons Mfg. Co., Kalamazoo, Mich., its territory covering the States east of the western boundary of Pennsylvania. They also handle the accounts of the Blood Bros. Machine Co., Allegan, Mich., and the Pierce Governor Co., Anderson, Ind.

—

Fosdick Plans Automotive Company

BOSTON, MASS., Nov. 11—The Harry Fosdick, Inc. was formed here to-day. While its primary object is to deal in Pathfinder cars for New England, its main object is to go into everything possible along the lines of automotive power. Mr. Fosdick has been working on the plans for the past 6 months. The charter grants the right to sell, manufacture, buy and deal in all automotive powers, including automobiles, aeroplanes, marine, railroad or anything else that moves with a motor. The company has a capital of $20,000, and has leased temporary salesrooms here.

Mr. Fosdick's idea is to begin operations to meet the future which he realizes will mean the adoption of motors more generally for aeroplanes, submarines, vessels of all kinds, and even for railroads. William Hilliard, who was formerly with him, and who spent much time with the Burgess Aeroplane Co., learning to handle aircraft, has joined him. Mr. Hilliard, who was also with the Pathfinder, is known as the winner of the Climb to the Clouds, and for winning the light car race at Savannah with a Lancia.

—

C. & C. Co. To Handle R. I. V. Ball Bearings

NEW YORK, Nov. 13—The C. & C. Sales Corp. has been formed by I. R. Caplan, formerly connected with the R. I. V. Co. and Belmont Corp., formerly purchasing agent for Fiat, Poughkeepsie, N. Y. The company will deal in various types of anti-friction bearings, having taken over the R. I. V. Co.'s entire stock, for which it will be retail sales agent.

—

Fulton Takes C. & E. Products

MILWAUKEE, Nov. 13—The Fulton Co. has taken over the entire output of the C. & E. Mfg. Co., Marshalltown, Ia., the principal products of which are cutouts, Ford wheel pullers, accclerators for Fords, pedals, fender braces and camshaft bearings for Fords. These will be distributed to the jobbing trade in the United States and Canada.

—

New 3500-Mile Alliance Tire

ALLIANCE, OHIO, Nov. 13—The Alliance Tire & Rubber Co., the corporation which has succeeded The Alliance Rubber Co., Alliance, Ohio, announces a 3500-mile tire for 1917, a product that will be marketed at a low figure to the retail trade.

—

Peter A. Frasse & Co. 100 Years Old

NEW YORK CITY, Nov. 13—"One Century in Business" is the title of a booklet just issued by Peter A. Frasse & Co., this city, Philadelphia, Buffalo and Hartford, commemorating the opening of its first store in this country. This company is one of the large dealers in steel tube and tool steel, also mechanics' tools and machinery supplies.

Plan Tests of Fuel Consumption

Wisconsin Good Roads Assn. to Determine Relative Effects of Road Conditions

MILWAUKEE, WIS., Nov. 11—Exhaustive tests and demonstrations to determine the relative consumption of gasoline by motor vehicles on different types of highways, and also on roads in good and bad condition, have been arranged by the Good Roads Assn. of Wisconsin. The tests will be undertaken as soon as possible under the direction of Prof. M. F. White, department of agricultural engineering, University of Wisconsin, with the assistance of F. A. Cannon, secretary of the roads association.

The first tests will be made in Milwaukee county, which contains more than 100 miles of concrete highway, and also many miles of poor dirt, gravel and macadam highways not yet improved, thus offering the extremes of road and haulage conditions. The work will be done in this manner: A wagon will be loaded with a fixed load of agricultural products, say 2000 lb., to which will be hitched a pair of horses. By means of a dynamometer the tractive effort, resistance or pulling power will be fixed and determined.

—

Allen Bour-Davis Southern Sales Mgr.

DETROIT, MICH., Nov. 11—Robert Allen has been made the southern district sales manager for the Bour-Davis Motor Co., Mr. Allen was formerly the manager of the Dallas, Tex., branch of the Chevrolet Motor Co.

—

Livingstone Maxwell Cleveland Manager

CLEVELAND, Nov. 12—J. Livingstone has been appointed manager of the Cleveland retail branch of the Maxwell Motor Co. Mr. Livingstone was formerly assistant branch manager for the Studebaker Corp. at Indianapolis and Omaha.

—

Cole Has Service Conference

INDIANAPOLIS, IND., Nov. 10—More than 100 service men employed by the various important distributors and dealers of Cole cars have been assembled in Indianapolis by the Cole Motor Car Co., for their first service men's conference to outline a new service program which has been adopted.

—

Miles Is Buyer for Lewis Motor

DETROIT, MICH., Nov. 13—F. E. Miles has become the purchasing agent for the Lewis Motor Corp. Mr. Miles was formerly connected with the National Motor Vehicle Co.

Paige Wins Desert Race

Negotiates 273-Mile Phoenix-Douglas Course in 8 Hr. 30 Min.—14 Entered

PHOENIX, ARIZ., Nov. 13—E. L. Cord, driving a Paige, won the 273-mile Phoenix road race in 8 hr. 30 min., or 30 m.p.h. P. Thomason, driving a Buick, came in third, his time being 8 hr. 40 min. Fourteen cars started and five of them finished.

Entry in the race was open to cars and drivers from Arizona, New Mexico and Texas, with the condition that both driver and entrant must have been a resident of one of the three States for 6 months prior to the race. The race started at Douglas and finished at the State fair ground, Phoenix. The course followed the Borderland highway from Douglas to Phoenix, including some of the fastest stretches of desert road in the southwest and some tortuous sections of mountain and desert road. Hugh Miller holds the course record of 7 hr. 4 min., in 1914, made in the Pope-Hartford that he drove to-day. The race was conducted under sanction of the A. A. A. and by the Arizona State Fair Commission.

—

Uniontown Speedway Nears Completion

UNIONTOWN, PA., Nov. 13—The local 1⅛ mile speedway is now nearly completed and will be ready for practice the latter part of next week. The total number of entries to date for the race meet on Nov. 30 is fifteen. In addition to the $4,250 offered in cash prizes for that day, C. W. Johnson, president of the speedway association, received a special prize in the form of a trophy valued at $3,000, to be known as the Universal Trophy, presented by Carl Laemmle, president of the Universal Film Mfg. Co. This trophy is to be contested for a period of 5 years at Uniontown, according to the terms on which it is offered.

—

Maxwell Makes Speed Test Run

DETROIT, MICH., Nov. 11—A Maxwell stock car, driven by Ray McNamara, completed a speed test from Detroit to Kalamazoo and return in 9 hr. and 45 min., covering a total distance of 350 miles, with an average running speed of 36 m.p.h.

The test was held, preliminary to the engagement of a Maxwell stock car in a contest which may arise as a result of the Maxwell challenge issued recently to all cars selling for $1,000 or less. The route taken included the towns of Lansing, Grand Rapids, Kalamazoo, Battle Creek, and Jackson, and the run was officially observed and checked by Detroit newspaper men. More than 50 per cent of the run was made over roads that were in the worst possible condition for touring and in several places the car was forced to make long detours because of construction work.

The start was made from Detroit at 3.15 a. m. and the car was checked into Detroit at 1 p. m.

—

Chevrolet Makes Promotions

OAKLAND, CAL., Nov. 13—R. C. Durant, son of W. C. Durant, has become sales manager of the Chevrolet Motor Co. of California. He was formerly assistant sales manager. W. A. Coleman has become assistant sales manager. Norman DeVaux has become general manager of that company, his former position being sales manager. They will make their headquarters at the local assembling plant.

T. L. Coleman has become sales manager of the Chevrolet Motor Co. of Canada, Oshawa, Ont., succeeding H. Horsman, recently resigned. Mr. Coleman was formerly with the Goodyear Tire and Rubber Co., New York.

—

Milburn Branch Manager for Hupp

DETROIT, MICH., Nov. 14—E. W. Milburn has been appointed branch manager of the Hupp Motor Car Corp. at San Francisco. He succeeds E. A. Morrison. Mr. Milburn was formerly the coast representative for the Thomas B. Jeffrey Co.

—

Timken Employees to Own Store

DETROIT, MICH., Nov. 14—The 3300 employees of the Timken-Detroit Axle Co. plan to reduce the cost of living by the operation of a store owned by themselves. It will be known as the Co-operative Store of the Timken-Detroit Co. and will sell food staples to all employees at the lowest possible prices. L. R. Judson, welfare manager for the company, will supervise it.

—

Vail Rubber Changes Its Name

CHICAGO, ILL., Nov. 13—The name of the Vail Rubber Co. has been changed to Ehman Tire & Rubber Co., under which name the business will be continued. A. C Ehman is president, the other officers being Francis Lackner, vice-president and N. J. Flynn, treasurer. The company makes pneumatic tires, packing, gaskets, and mechanical rubber goods.

—

Olympian Offices in Pontiac

PONTIAC, Nov. 13—The general offices of the Olympian Motors Co. have been moved into the main office building formerly occupied by the old Flanders Mfg. Co.

Amateur Races for Chicago?

Series May Be Run on Speedway Under Mid-West Motor Club

CHICAGO, ILL., Nov. 10—It seems possible that next year will see a series of amateur races run on the Chicago speedway quite similar to those that were fortnightly events on the Brooklands track prior to the war. These races probably will be run under the auspices of the Mid-West Motor Club, which was formed this week by a number of those who took part in the amateur races held here this year and present plans include competition among all cars up to and including 230 cu. in. piston displacement.

—

American Speedways Assn. Formed

CHICAGO, ILL., Nov. 15—Speedway managers met here to-day and formed the American Speedways Assn. in the form of a national organization to standardize racing conditions and to draft up uniform regulations and co-operations in getting drivers in all events.

The meeting to-day held at the Chicago Automobile Club is the culmination of a number of previous futile attempts to organize during the past 18 months.

At this meeting a constitution was adopted and officers elected as follows: president, Harry Harkness, New York Speedway; vice-president, Allison, Indianapolis Speedway; treasurer, H. S. Lehman, Cincinnati Speedway; and secretary, T. E. Meyers, Indianapolis.

The following speedways had personal representatives present; Indianapolis, Uniontown, New York, Providence, Des Moines and Chicago. Cincinnati and Omaha sent proxies.

In the newly formed organization there are two classes of membership. Class A is open to speedways having a course of 2 miles in length or over and class B is open to speedways having a course of less than 2 miles. In each case those speedways will be admitted whose construction is approved by the membership committee of the association. Chief control will be in the hands of a governing board consisting of three representatives of class B and four representatives of class A. The governing board consists of Allison, Harkness, Reid, Lehman, and C. W. Johnson, of Uniontown, as class A members. F. H. Perkins, Providence and Samuel Orloff, Des Moines, are members of class B. The governing board and officers elected will serve until the next meeting in New York, Jan. 12.

The American Speedways Assn. supercedes the Speedways Assn. of America which it was intended to organize earlier in the year.

Convincing Advertising

THE advertisements of the concerns constituting any industry is in general a good indication of the business ethics of that industry. In all new industries more or less undesirable advertising is bound to be published, but it is a satisfactory indication when a national organization such as the National Automobile Chamber of Commerce takes up the problem of advertising with the object of discouraging what might be classed as scare or fear copy and lending its influence to more positive forms of publicity.

Potential Quality Doubted

While scare, or fear, advertising might be looked upon as potential still it is questionable, after administering the psychological test, if such copy is as potential as other copy might be. There is generally a positive and a negative aspect to each subject. A good positive example of advertising is that of the Pennsylvania Railroad, which advertises the number of passengers it has carried over a certain period without a single loss of life. It would be difficult to find a more potential kind of copy. Other positive railroad advertising has had to do with block-signal systems, rock-ballasted roadbed, full crews and other assets.

Contrast such advertising with that copy which might be used, showing trains on their side in the ditch, passenger cars on fire and women and children being rescued, engines colliding head-on and trains crashing through weak bridges. Such fear copy that might be used would in general build up through the traveling clientèle a feeling of fear, a feeling that would not engender a love for travel, but that would rather induce you to stay at home. The effect would be negative rather than positive.

Negative Tendencies Undesirable

In all advertising copy relating to automobiles and the industry the message to be conveyed is not one of fear or scare but one of desire to own and use an automobile. Every picture used in an advertisement that suggests accidents and the horrors that follow them is a possible source of injury. It has a negative tendency in that its influence breeds fear for the automobile rather than confidence in it.

Clutches and Winter

MISSING motors and clashing gears seem to be particularly common in the cold weather which has just commenced to settle over the country. The first item can of course be laid at the door of the heavy fuel which is difficult of vaporization. The second, however, can be traced to a defect which should be rectified in some of the clutch designs.

There is a tendency to drop the clutch brake and in place of this substitute a quick releasing device which will disengage the driving from the driven members instantaneously. This trend of design is no doubt a matter of progress, but one phase which must be watched is that the stiff lubricant which is attendant upon cold weather does not interfere with the action of the clutch.

The lighter weight clutches which are coming into use year by year naturally have less tendency to spin, and therefore lessen the danger of clash and also are not prone to drag. The effect of the heavy oil on even a light-clutch member is sufficient at times to give this clash. In fact, it will be so severe in some instances that it is difficult to pull the gears out of mesh after the clutch pedal is depressed, and when they are re-engaged the grinding noise which is particularly noticeable at this time of year ensues.

The remedy is, of course, in having the disengaging mechanism positive as well as quick. At the same time the leverage on the clutch pedal must not be reduced because with the ever-increasing number of women who drive it is necessary to keep in line with the tendency of having the force required to disengage the clutch as small as possible. Furthermore, the amount of motion of the pedal cannot be too great, because it will make the car unsuitable for a large number of leg lengths. This opens up a problem which is of course nothing new to the clutch builder. The amount of clutch member travel must be small, it must be quick to reduce spin, and in all the lubricated forms of clutch it must be absolutely unaffected by changes of oil viscosity due to temperature changes.

Steering Gears Offer Many Opportunities

Details of Layout and Construction Present Field for Enterprise—Truck Type Problems Differ from Passenger Car Requirements—Elimination of Wear

By J. Edward Schipper

STEERING gear design is largely a matter of compromise. It is a compromise between what is mathematically perfect and what is attainable practically; between stress on the driver and stress on the mechanism; and again between quickness of action and effort required to manipulate.

With this three-fold problem, each having its answer in a compromise, it is human to conclude that there will be a great variation in opinion, and this is true regarding the generalities of steering gear design as well as of the details.

Steering gears are probably the part of the car which has undergone the least change in the last 5 years and there are many cars to-day using the same gear as they did in 1912, with the exception of a few refinements in the direction of reduced weight and the changes required in shifting the gear from the right to the left side of the car.

Two big factors enter the design of the steering gear, and these determine practically every point in relation to the gear. They are:

First—the car weight.
Second—the car speed.

The layout of the gear is governed largely by the wheelbase and the structural details of the frame, but the steering gear itself depends upon the two factors named.

Truck Designs Differ

Because a truck is heavier and slower than a passenger car, it necessarily has a different kind of steering gear. Theoretically the layout would be the same for both machines if they were of the same wheelbase, but practically, it is necessary to have a great reduction in the truck because it is heavier and naturally takes a greater leverage to turn the wheels; and secondly, since the truck acts at a slower rate of speed, the reduction can again be greater because it is not so necessary to be able to turn the wheels from one side to another so quickly.

Owing to the great inertia of a moving loaded truck it is not desirable to make quick turns with the front wheels on account of the tremendous stresses involved by the inertia force and the high center of gravity. With a passenger car, the wheels must turn quickly in order to make the vehicle good for traffic work.

The passenger car problem calls for the reduction gear in the steering mechanism to have a final ratio that will give the result desired in quickness and at the same time the gear must prevent the reception of road shocks by the driver, or, in other words, it must not allow the wheels to be swung out of their proper line or the steering wheel turned by every little impact between wheels and road obstructions. In other words, the gear must be to some degree irreversible.

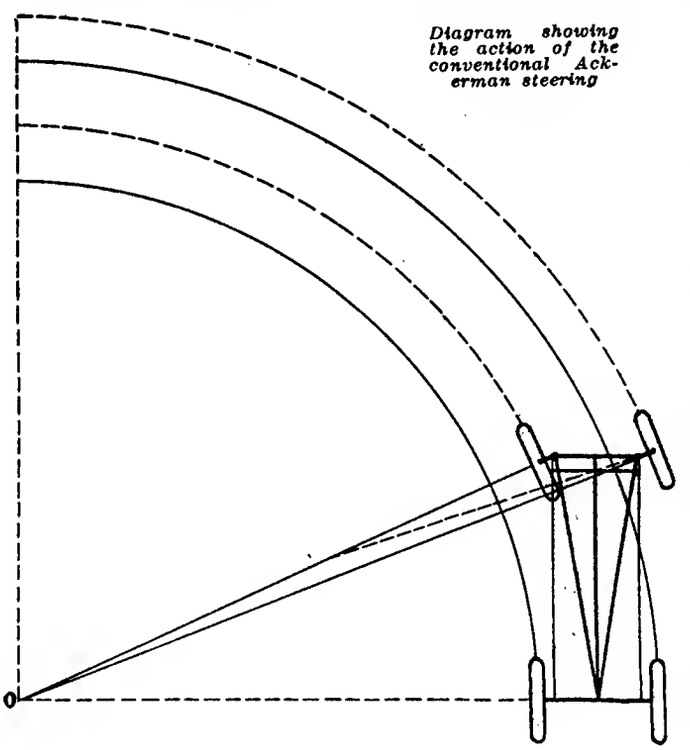

Diagram showing the action of the conventional Ackerman steering

The term irreversible in itself is confusing, because it has no exact meaning when applied to steering wheels beyond the rather indefinite condition that it means that any ordinary road wheel impact will be insufficient to turn the steering wheel. It is simply a question of reduction between worm and gear, sector or nut, whichever system is used. The greater the reduction, the less reversible the system and likewise the slower the motion of the road wheels in relation to the movement of the steering gear. Hence,

the steering gear for a heavier car will be normally less reversible than the steering gear for a lighter vehicle.

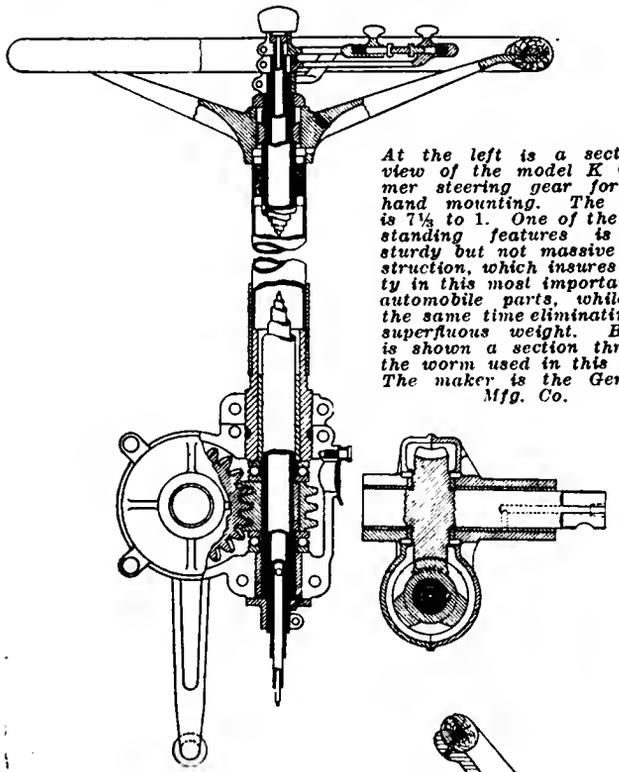
Elimination of Wear

The straight mechanical problem of steering gears is to eliminate wear. This occurs in all the joints, the order of progress of wear being first the link joints at either end of the drag link and tie rod; and next between the worm gear or nut and the swivel joints. The order of wear is very much the same as the order of lubrication difficulty, and where the different steering gears differ largely is in these points where different styles of ingenuity are employed to get the joints so that they will retain the grease and at the same time allow it to be applied at the proper points.

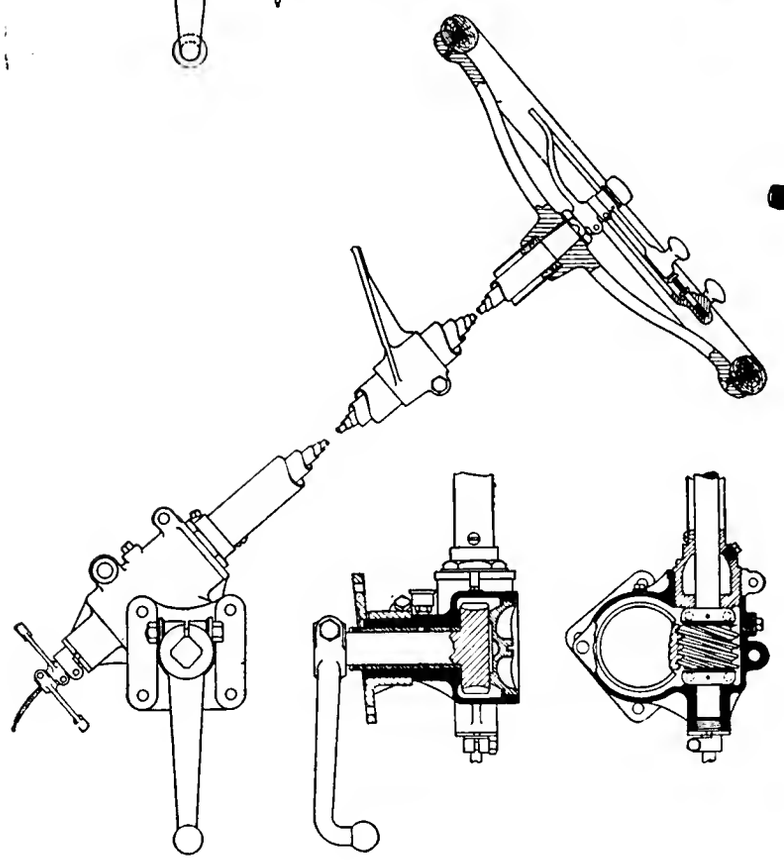
There is also a variation in the grades of lubricant used. The Warner company, for example, recommends a heavy graphite grease as a general rule, although it states that in very cold weather a thinner oil would be of advantage. The great point of importance is that the oil or grease is retained in the gear once it is put there so that the operation of oiling the gear will not have to be repeated over frequently.

Lubrication Points Inaccessible

There are at least seven important points to lubricate on a steering gear, and none of them is accessible for a man who has good clothes on, therefore, as far as the passenger car owner-driver is concerned, he will not lubricate the gear until two conditions obtain, first that he has on a set of working clothes and second that he thinks of the gear. In many cases the first of these circumstances is rare, and in many more instances the second circumstance is still more rare. The combination of the two, therefore, will be so much of a long chance that steering gears must be designed to hold enough oil and grease to furnish lubrication for a long time. The majority of steering gear manufacturers favor a light transmission grease.

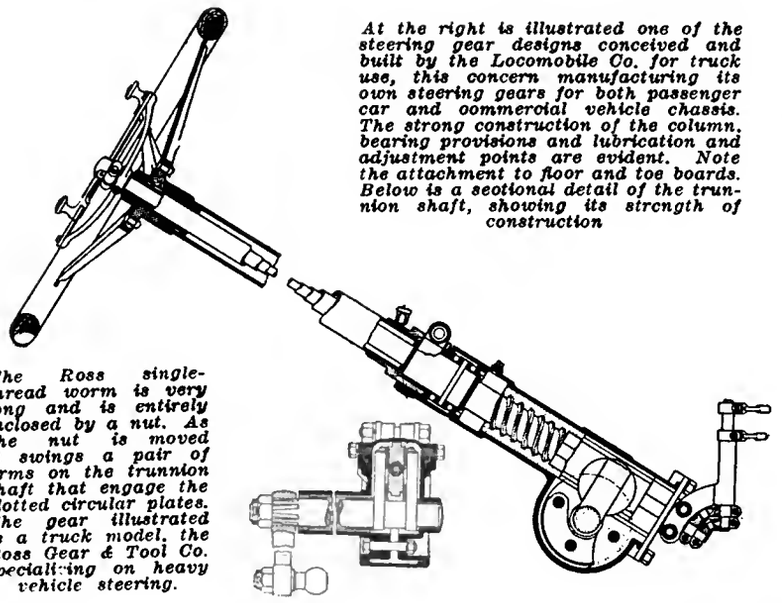


At the left is a sectional view of the model K Gemmer steering gear for left hand mounting. The ratio is 7½ to 1. One of the outstanding features is the sturdy but not massive construction, which insures safety in this most important of automobile parts, while at the same time eliminating all superfluous weight. Below is shown a section through the worm used in this gear. The maker is the Gemmer Mfg. Co.



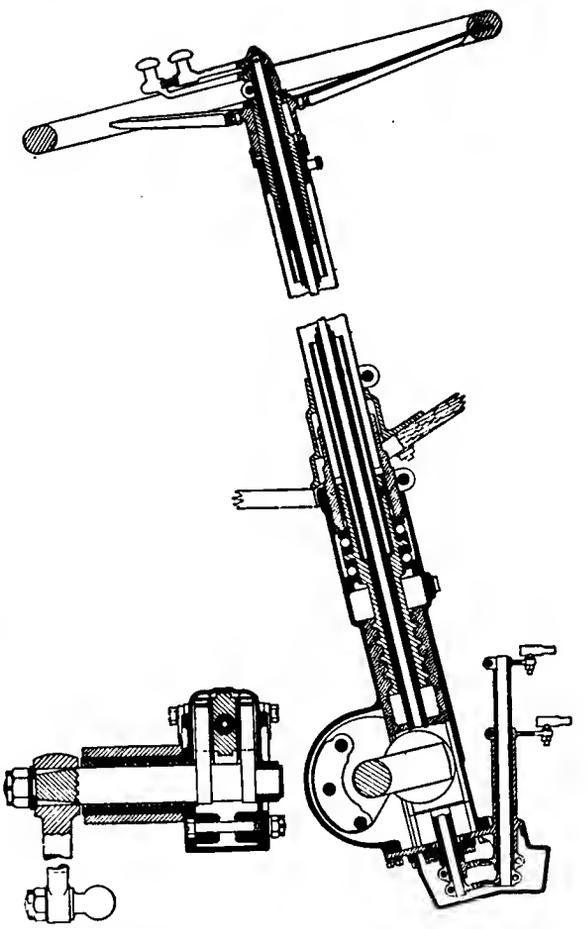
Above is the Lavine gear which uses a divided nut operating on right and left hand threads cut in a double worm, each of the blocks of the nut having a worm. The steering arm is operated through a rocking arrangement. To the left of the steering gear is a detailed section showing the trunnion shaft, its bushing, trunnion block, etc. The Lavine Gear Co. is the manufacturer

To the left is a Warner steering gear which is widely used and which is representative of modern worm and wheel practice. There is an adjustment for the thrust bearing behind the worm. Note the bracket midway up the steering column for attaching to the cowlboard or dash and also wiring for the horn. Immediately to the right of the steering gear is a sectional view showing details of the trunnion-shaft and farther to the right is a similar illustration of the worm assembly. This gear is made by the Warner Gear Co.



The Ross single-thread worm is very long and is entirely inclosed by a nut. As the nut is moved it swings a pair of arms on the trunnion shaft that engage the slotted circular plates. The gear illustrated is a truck model, the Ross Gear & Tool Co. specializing on heavy vehicle steering.

At the right is illustrated one of the steering gear designs conceived and built by the Locomobile Co. for truck use, this concern manufacturing its own steering gears for both passenger car and commercial vehicle chassis. The strong construction of the column, bearing provisions and lubrication and adjustment points are evident. Note the attachment to floor and toe boards. Below is a sectional detail of the trunnion shaft, showing its strength of construction



In the design of the gear itself, it is generally believed that the kind of gear employed is not so important as to have the gear of proper design. This materially affects the lubrication, as it bears directly on the pressure exerted on the surfaces. The pumping effect on the steering gear is very slight, so it is difficult to keep the lubricant properly distributed and therefore another feature to compromise arises. The unit pressures must be kept down on one hand, and, on the other hand, the thread area of the worm must not be too great.

The Two Schools of Design

Referring this matter to the two different schools of design, the worm-and-split-nut and the worm-and-gear, the probabilities are that in the worm-and-gear type the pressures run quite high, because of the nature of the gears there is simply a line contact; whereas with the worm-and-split-nut type the thread area has a tendency to become so large that it is difficult to permit the lubricant to reach the innermost threads unless a very light oil is employed.

Allowable Backlash

All the wear in the different joints is reflected in backlash in the steering wheel. Fortunately, adjustments are provided on all the gears to get this lash out, because it becomes annoying at first and then dangerous, as a car with too much is apt to commence swaying on a down grade, and the sway becomes greater and greater until it reaches the limits of safety unless retarded.

Exactly what should be the allowable backlash in the steering wheel is subject to a difference of opinion. The Jackson, Church and Wilcox company states that the ideal is a 0 backlash. Warner states from 1 to 1½ in. is permissible. As a matter of fact, everyone knows that it should be kept as small as comfortable. Even drivers will differ, however, on what constitutes a fair amount of play and what is bothersome, but the steering gear manufacturer cannot adjust every product to the individual desires of the driver, so a standard has to be set and adhered to in each factory, and this ranges between the limits of practically 0 to 1½ in. A slight play generally helps to reduce shock.

Steering Pivot Tilt

If there is one change in steering gears, it is probably in arranging the steering pivot tilt. This has been increased in the last year or two, in order to help in attaining the so-called castor effect. In laying out the steering gear on the Willys-Overland cars, an angle of more than 5 deg. is given every steering pivot, to make it hold the road. On the other hand, a tilt of more than 10 deg. is extreme and it will be very difficult to make the car hold a turn on account of the great tendency for it to straighten out. This would make a desirable car on a long, straight road, but an undesirable one on a twisting road. Here again there must be a compromise and a moderate tendency to straighten out gained, without causing a tiring effort to hold the wheels on turns.

Tilting the Axle

Tilting the axle gains the same effect as tilting the steering spindles and even the flattening of the front springs has been a decided help in making cars hold the road. It is not all design, however, as soft front tires will counteract the best of steering layouts, or if the weight on the rear axle is greater than that on the front, there will be a decidedly unbalanced car to drive, the tendency being for the car to try to have the rear end catch up with the front wherever the course deviates from a straight line or lies over a slippery stretch.

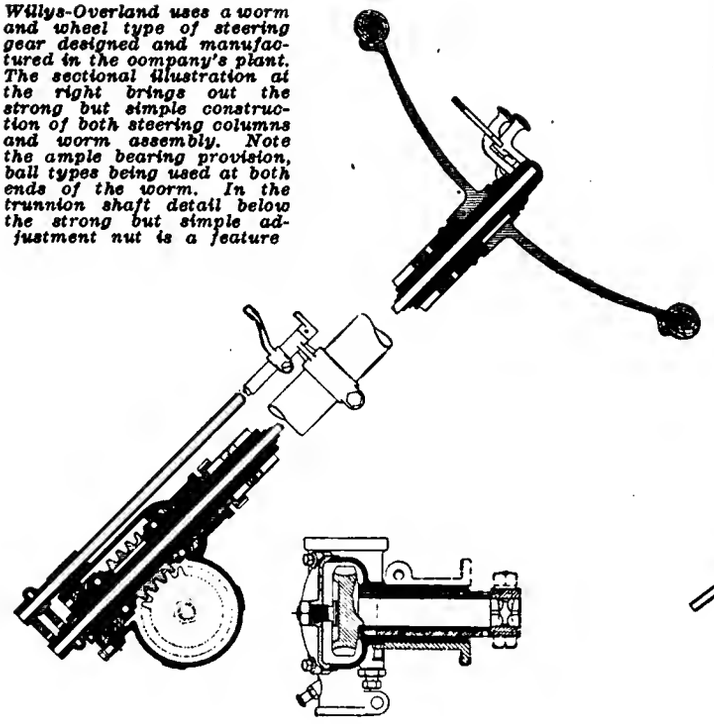
Adjustments Are Complete

Steering gears are all particularly complete in the matter of adjustments. This allows the driver to hold the backlash in the gears to just about the desired amount. Play in the wheels that is not detected in the steering wheel is due to variations in tightness of the linkage, and signifies worn parts, generally those which have either been neglected by the driver or which have bearing surfaces that are too small for the loads the gear is called upon to stand and hence have worn away too rapidly.

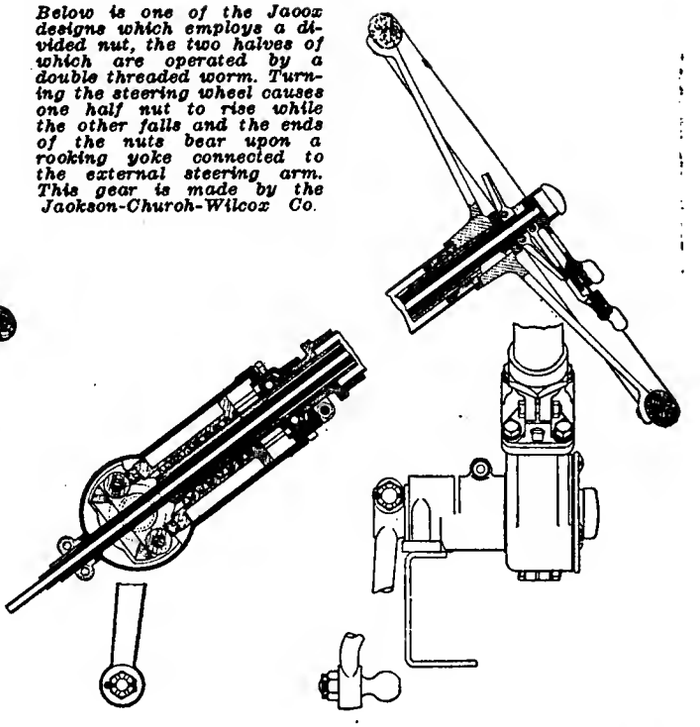
Bearings Are Renewable

Bushings are renewable even in the case of the worn parts, so that steering gear maintenance is really on about as good a basis as anything on the car. The trend of the times, however, will probably cause an improvement in gears in the

Willys-Overland uses a worm and wheel type of steering gear designed and manufactured in the company's plant. The sectional illustration at the right brings out the strong but simple construction of both steering columns and worm assembly. Note the ample bearing provision, ball types being used at both ends of the worm. In the trunnion shaft detail below the strong but simple adjustment nut is a feature



Below is one of the Jacox designs which employs a divided nut, the two halves of which are operated by a double threaded worm. Turning the steering wheel causes one half nut to rise while the other falls and the ends of the nuts bear upon a rocking yoke connected to the external steering arm. This gear is made by the Jackson-Church-Wilcox Co.



way of self-lubrication and again in self-adjustment. The self-aligning feature comes with the castor effect, the others are still waiting for full development. Oilless bearings are suggested for parts of the gear that do not have a great amount of motion, and they have been tried extensively and are in some use.

Worm-and-Wheel Adjustment

With the worm-and-full-wheel gear there are two adjustments possible; one method is to turn the eccentric bushing at the center of the wheel and the other is to turn the wheel, bringing a new surface into engagement with the worm. As the whole wheel is not used at once, this gives all of the effect of a new wheel. The latter method is generally preferred by manufacturers and it is recommended that the adjustments be made generally in this manner.

With the worm-and-split-nut type of gear, adjustments are simple. The Jacox gear is an example, as the gear is adjustable for wear by one single adjustment, and this is quite accessible. The adjustment is accomplished by loosening the bolt in the housing cap which locks the adjusting nut. The adjusting nut is then screwed down and locked. The adjusting nut bears directly on the thrust bearing which rests on the shoulder of the screw. When the adjusting nut is turned down, the screw is forced down against the threads of the half nut, the half nuts are in turn forced down against the rollers of the yoke shaft, taking up the wear on the threads of the half nuts and on the rollers.

Mechanical Layout Problems

Mathematically the layout of the steering gear presents a problem with ramifications that are not approached in any other part of automobile design. The mere statement of the problem of getting two pairs of wheels, one stationary and the other movable axially, to roll around a given point without sliding is sufficient to indicate the impossibility of ever securing in practice mathematically correct steering. As a matter of fact, the variation from the perfect is not so great as would at first be supposed, and although it cannot be said that the past year's improvement has brought us any closer to it, still steering, taken as a whole, is not unsatisfactory.

Practically every automobile has the same type of steering so far as the system is concerned, the Ackerman. With Ackerman steering it is assumed that the tie rod arms projecting from the swivels should meet at the middle point of the rear axle if their center lines are produced. Now, when on a curve the two rear wheels roll on two circular paths of different radii, and each wheel makes a tangent to its rolling circle, as viewed in plan. The front wheels meanwhile roll on separate circles of their own and the ideal steering gear is such that each of the four wheels should make a tangent to the circle along which it is rolling.

This true rolling can occur at three positions only: One is the straight position when the car is turning neither to right nor left, and the other where two wheels are at some definite angle of lock to right and left respectively. The effect for all other positions is that three wheels may roll perfectly, but the fourth must do some skidding, or perhaps two wheels roll and the other two divide the skid.

When Skidding Occurs

It is obvious that the rear wheels must roll on concentric circles and that the rear axle center line produced must be the diametrical line of the circles. Thus neither one of the rear wheels can skid unless both do. Suppose the point about which the car is turning is O, then the center lines of both the front wheel spindles must meet at O if every wheel rolls perfectly, without skidding. It is obvious that by turning the steering wheel we can bring one of the front wheels into such a position that the spindle center line passes through O, but the second front wheel will then take up a position depending upon the length of the tie rod and the layout of the tie rod arms.

Necessarily a Compromise

The practical geometry of steering gears involves a considerable amount of thought regarding the angles of the links and the intersections of link lines produced, and, as stated, the result from a commercial standpoint must always be a compromise. The difference between really good steering, however, and that of the average car is so marked that any improvements which would tend to make practice line up to a closer degree with theory would be welcomed, not only by the car owner but also by the industry.

Gearsets Simplified and Refined

Main Elements of Design Practically Unchanged—Adaptation to Unit Power Plants and Center Control a Continued Development—Provision for Tire Pump and Speedometer Drive

By Donald McLeod Lay

GEARSETS and clutches are so nearly inseparable in these days of unit power plants that the latter may well be included in a summary of the tendencies and refinements which mark the progress of gearset design during the past year. As was the case in 1915, there have been no radical alterations in construction or changes in basic principles. The leading tendency manifested during this year may be characterized as a general trend toward simplification, not only in manufacture and in the number and type of gearsets produced by each factory, but also in the reduction of the number of parts and slight alterations in the design of others which succeed in doing away with more or less complication and its inevitable accompanying weight.

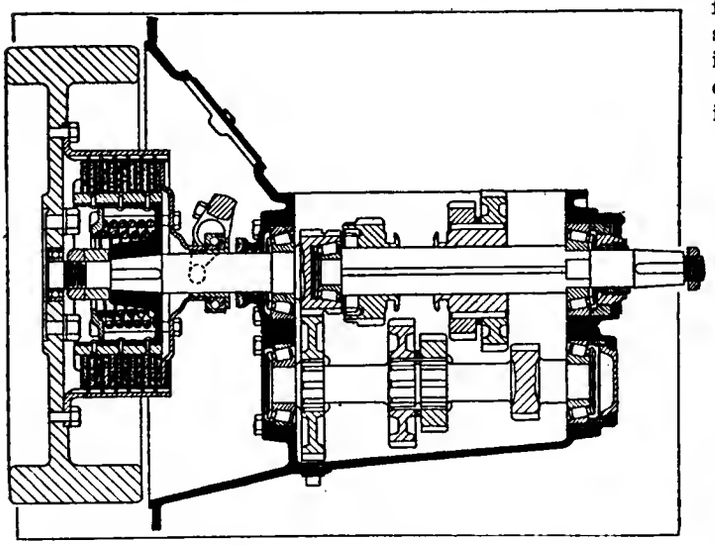
Unit Power Plant Gains

The continued trend toward unit power plant construction which became evident to such an extent last year has been emphasized by the increased production of multiple-cylinder engines, most of which are of the unit design. Naturally, gearsets have been improved in their adaptability to this type of mounting, not only by the methods of attachment, but also by the shape and construction of the bell housing, mounting of the clutch and improved bearing arrangement, although there has been comparatively little change in the latter respect. It was pointed out last year that the general adoption of the unit power plant had not led to the use of plain bearings throughout the gearset with pressure lubrication from the same oil pump that supplies the engine, and the comment was made that this seemed remarkable in that such a development could logically be expected. This year, however, there has been no trend toward such a construction. The manufacturers have not been idle on this question, but those who have been conducting experiments in the effort to arrive at a practical solution of the problem report almost unanimously that difficulty of securing satisfactory lubrication has to date rendered this impossible. Thus, ball or roller bearings continue to hold in practically all constructions for both portions of the mainshaft and, in fact, while some may consider them slightly more noisy than the plain bearing which they consider as the ideal, all the makers recognize their efficiency as a very close approximation of the latter.

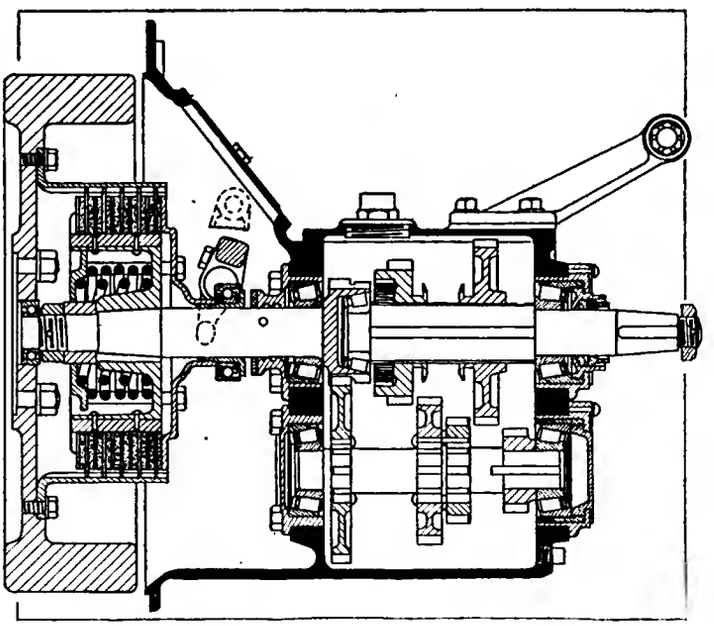
Iron has been increasing in favor as material for gearset housings, largely due to two considerations. One of these is the present high price of aluminum, and the other is the fact that iron seems to make a quieter casing than aluminum, in spite of being a more resonant metal. The greater rigidity of iron is one explanation put forth for this apparent contradiction.

Center Control Still Growing

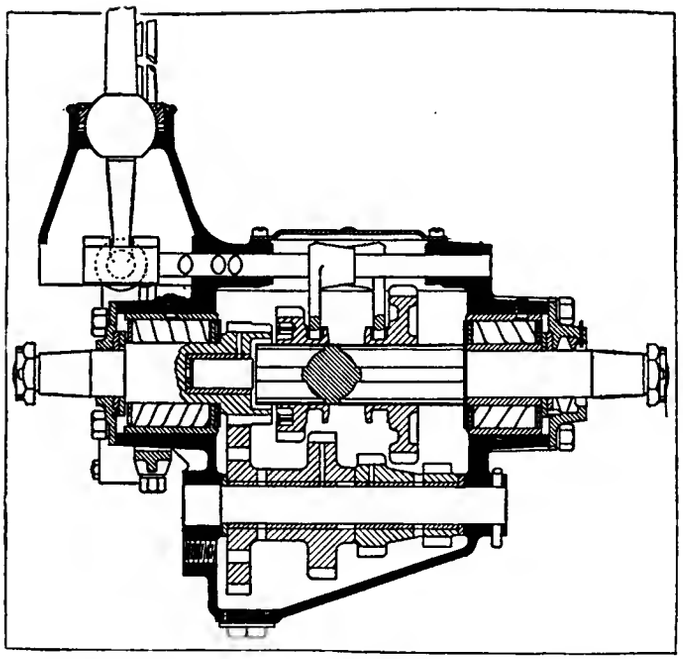
Center control, like the unit power plant construction, has been gaining so steadily that it is now almost standard, especially in the small, low-priced cars. The gearset manufacturers have welcomed this trend from the beginning, as it simplifies their work not only in designing and manufacturing their product, but also in the matter of expense, as it eliminates an enormous amount of material for rods, shafting, etc., which was formerly used up in adapting the stand-



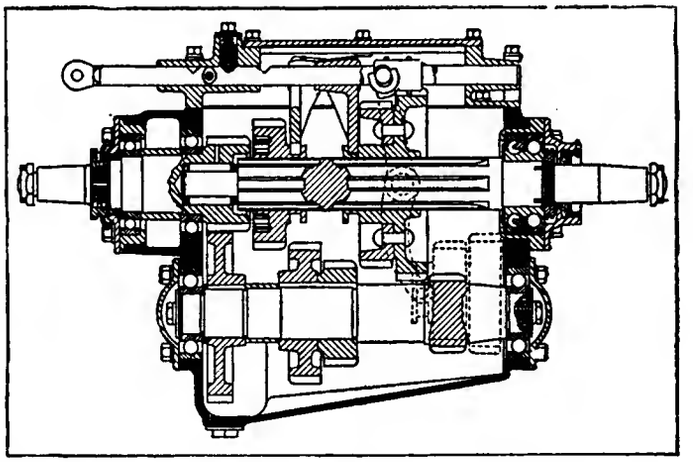
Above—Brown-Lipe four-speed gearset for unit power plant mounting. The company finds the demand for four-speed types for commercial car work to be gradually increasing, this applying especially to 3½ and 5-ton trucks. Where used for this purpose the gearset is universally furnished with direct drive on fourth speed



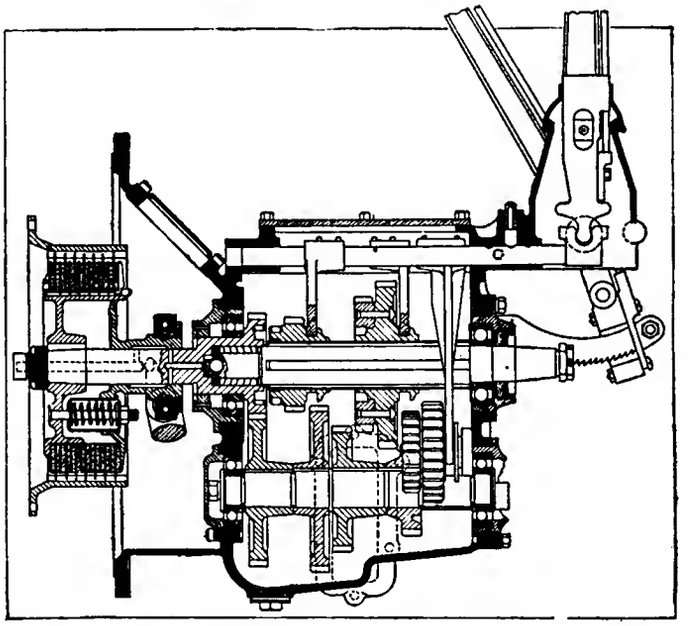
Right—Three-speed Brown-Lipe gearset, which is very like the four-speed design, having the same taper roller bearings. The sliding shaft is of square section. The use of a double clutch spring is characteristic of Brown-Lipe practice



Warner three-speed and reverse gearset with gears at ¾ in. space and 6-8 pitch. The main shaft is round in section with four integral keys and is carried at one end in a Hyatt roller and the spigot at the opposite end in a plain bushing with oiling facilities adequate to all conditions



Warner four-speed and reverse gearset with both shafts carried on annular bearings and with a spigot end of the main shaft carried on a roller bearing within the stub shaft. The main shaft has six splines on which the sliding gears move. The gears are nickel steel 1¼ in. face and 5-7 pitch. The speed reductions are: 4.99-1; 3.16-1; 1.79-1; 1-1, and reverse 5.78.1. Single race annular bearings are used for the countershaft. There is a double race bearing at one end of the main shaft and two single race bearings well spaced to support the short shaft at the opposite end



Warner four-speed and reverse gearset with nickel steel gears ¾ in. face and 6-8 pitch. Single race annular ball bearings carry both shafts. The spigot bearing on the end of the main shaft is supported in a Hyatt roller within the short shaft, and at this point end thrust is taken by a single ball. The gear ratios are: 2.73-1; 1.53-1; 1-1 and 1-1.251. The clutch assembly is a multiple disk type

ard gearset to the special requirements of various chassis.

While some of the gearset concerns still make it a practice to bring out special designs of housing cover plate and control lever mounting to suit the requirements of their customers, the majority build a standard design for center control chassis and adapt it to varying constructions by bending the levers either hot or cold. Regular models are usually available for right and left side lever mounting.

During the past year the makers have been able to still further simplify and refine their control mountings as compared with the 1915 designs, and many of them have arrived at such a point of development that it is necessary to cut only one hole in the floorboard for the passage of the levers, which are mounted, almost as a rule, upon the tops of the gearboxes. The connections between the control lever and the gears have been minimized and shifting is now very simple, requiring almost the least possible number of motions through the smallest distance, besides calling for the expenditure of considerably less energy than was the case in previous years. Last year much progress was made in this direction with the gearsets, but clutches lagged somewhat, a situation which has largely been remedied during the past 12 months by the increased popularity and more general adoption of the dry-disk type, which has now secured a commanding lead over its old rival, the cone. One of the greatest advantages of the dry-disk type is that the inner member can be made extremely light, so that shifting becomes correspondingly easy. Furthermore, for such a light-weight clutch no clutch stop or brake is necessary and the action is equally easy whether the operator is changing from an upper gear to a lower or the reverse. A good clutch brake makes the upward shifting with a cone clutch as easy as with the disk type, provided the weight is kept fairly low, although the extremely light construction which characterizes the dry disk is out of the question with a cone construction.

Clutches Are Better Inclosed

Clutches naturally share in the advantages conferred upon the gearsets by improved methods of inclosure. As an example of the progress made toward the ideal of a small, light, compact clutch unit of maximum efficiency as a transmitter of power, the Borg & Beck three-plate, dry-disk type may be mentioned. This unit also is fitted with a simple method of adjustment, requiring only the shifting of two bolts arranged diametrically opposite one another and working in slots in the housing. One mount produced by this firm combines a flywheel and clutch chamber in one casting. The other model is characterized as a self-contained design, the clutch being furnished in a separate inclosed casing which has a mounting-flange that bolts against the flywheel web.

One of the special features of this clutch is the ease of cleaning. Kerosene may be squirted into it, washing out the gummy substance which is caused by the sediment which mixes with the oil. The clutch may slip for a time after the kerosene has been applied, but the slippage soon disappears.

The four-speed gearset is now used in only a few of the

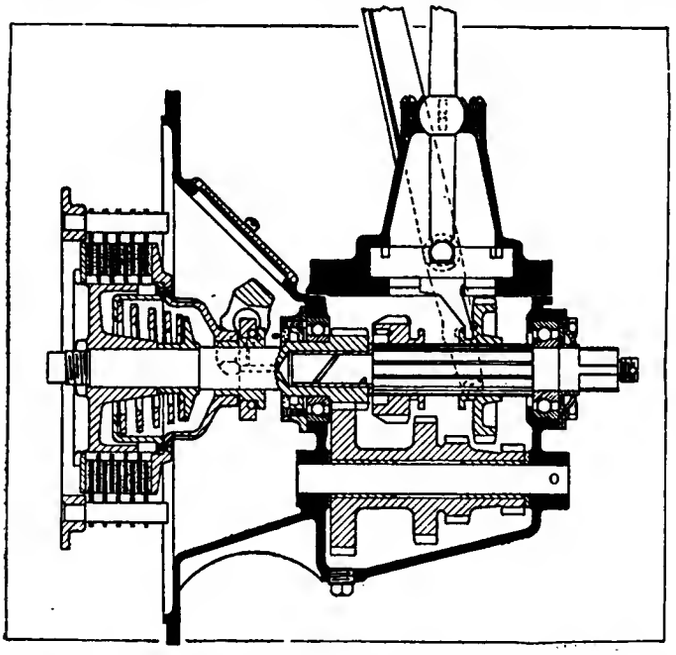
high-priced cars, the development of multiple-cylinder engines rendering it unnecessary except as an additional refinement or touch of luxury. Three speeds may now be considered practically standard for gasoline passenger car construction. For truck use, however, the four-speed gearset is becoming increasingly popular, Brown-Lipe pointing out that this type is in growing demand, especially for 3½ and 5-ton trucks. The Cross Gear & Engine Co. finds an increasing demand for 1-to-1 ratio on high where four-speed constructions are used for commercial vehicle chassis.

Gear ratios have been determined by the manufacturers largely through observation during years of experience and experimentation. Brown-Lipe is an example of this, others being Mechanics Machine Co., American Die & Tool Co. and Grant-Lees Gear Co. The Warner Gear Co. states that too much variation in the conditions of the range covered by standard models prevents the provision of ideal gear reductions. This company endeavors to arrange the gears approximately in geometrical progression, varied of course, according to circumstances.

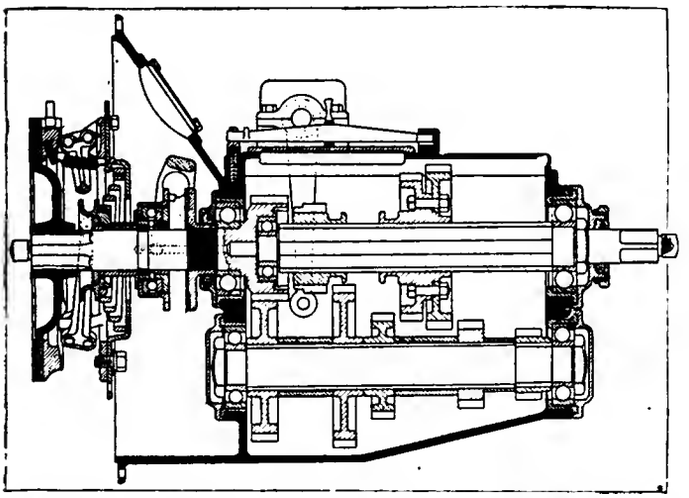
There seems to be some tendency toward the wider use of a stationary countershaft. Either plain bushing or straight roller bearings within the countershaft gears are used as a rule. With the Warner Gear Co. construction the countershaft gears are cut in pairs mounted on plain bronze bearings and the two pairs are driven by clutch jaws between them. Integrally forged countershaft gears are used by a number of makers, the Mechanics Machine Co. using this construction on the four counter gears used in its smaller gearsets. Brown-Lipe makes the three smaller gears integral in its smallest model, mounting them on a plain-bearing countershaft. The American Die & Tool Co. uses a built-up countershaft with sliding gears bolted together in one model while in another it uses the solid forging with extensions at the ends which support it in the case and which run on ball bearings.

Interlocking Devices Universal

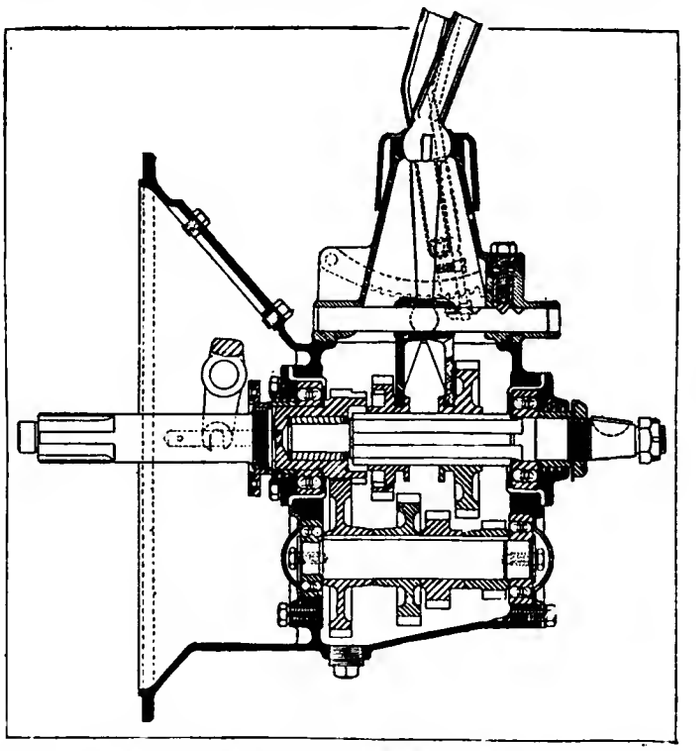
Interlocking devices to prevent the meshing of more than one gear at a time are almost universal. The Warner Gear Co. employs vertical plungers to give the gears their proper meshing position and plungers with a cross movement prevent more than the shift rail being moved at any given time. The Mechanics Machine Co. uses a small steel plate cast into the gearbox cover, this plate being notched for the gear change lever so that it is impossible to engage two speeds at once. When one set of gears is in mesh the lever is at one side of this plate and it is necessary to bring this through the notch and over to the other side of the plate before another set of gears can be brought into mesh. Three types of interlocks are used by the American Die & Tool Co., the ball or rod with spherical end between shift rods and the tilting bar mounted on a bracket underneath the sliding forks which



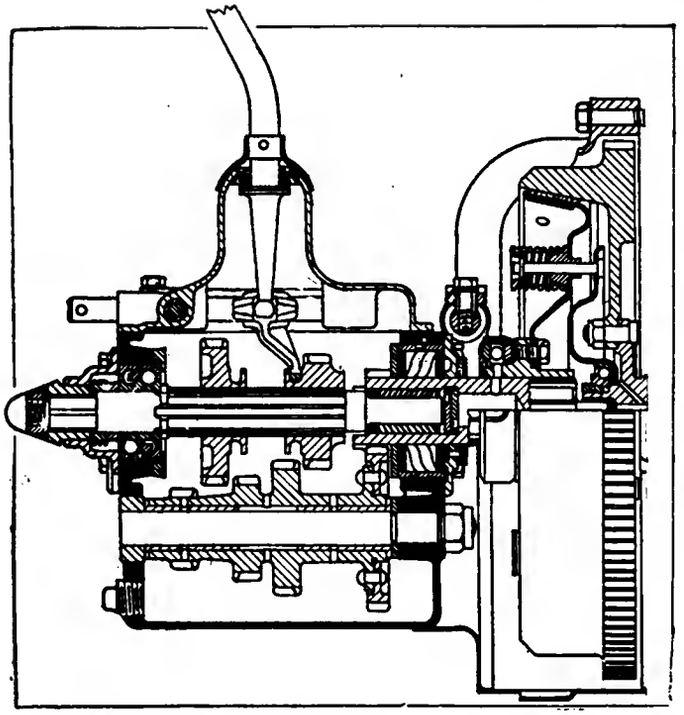
Mechanics Machine Co. three-speed and reverse gearset in which the main shaft is carried on annular bearings and the countershaft on plain bearings. The spigot end of the main shaft is carried in a plain bearing within the stub shaft. The main shaft is splined for the sliding gears. The ratios are: 1.5-1 on intermediate, and 3.4 to 1 on low. The clutch assembly is a multiple disk type with an inclosed conical engagement spring. There is a ball thrust collar for clutch disengagement



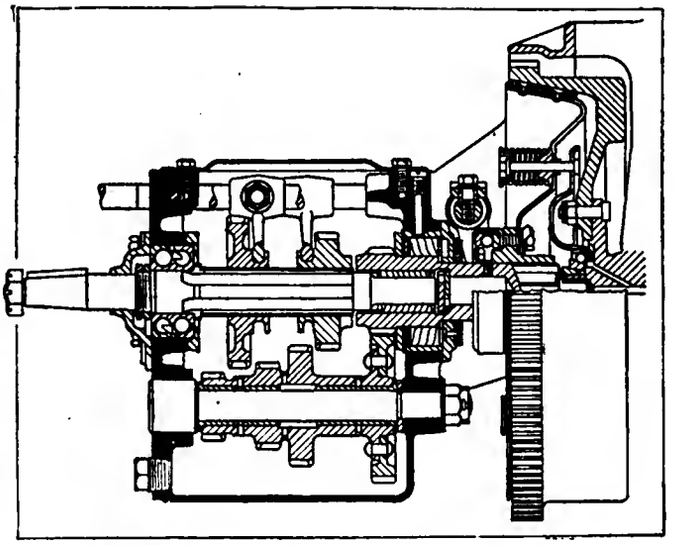
American Die & Tool Co. four-speed and reverse gearset with ball bearings for carrying main and countershaft as well as the spigot end of the main shaft. The main shaft is a circular cross section with 4-in. integral keys. The clutch assembly is a three-disk type with conical engagement spring and ball thrust collar for clutch actuation



Grant-Lees three-speed type of gearset. Gears are renewable separately and only one control housing is made. This is designed so that it is necessary to cut only one hole through the floorboard, the levers being bent cold to accommodate different bodies. Grant-Lees has changed from the gland stuffing box type to the spiral lead end plate



Northway three-speed design with reductions in the gearbox of 3.09 to 1 on low gear, 1.73 to 1 on second and direct drive on third. The reverse ratio in the box is 3.98 to 1. These ratios are, of course, multiplied by the rear axle for final reduction. The clutch used in this installation is a cone type with a ball bearing release

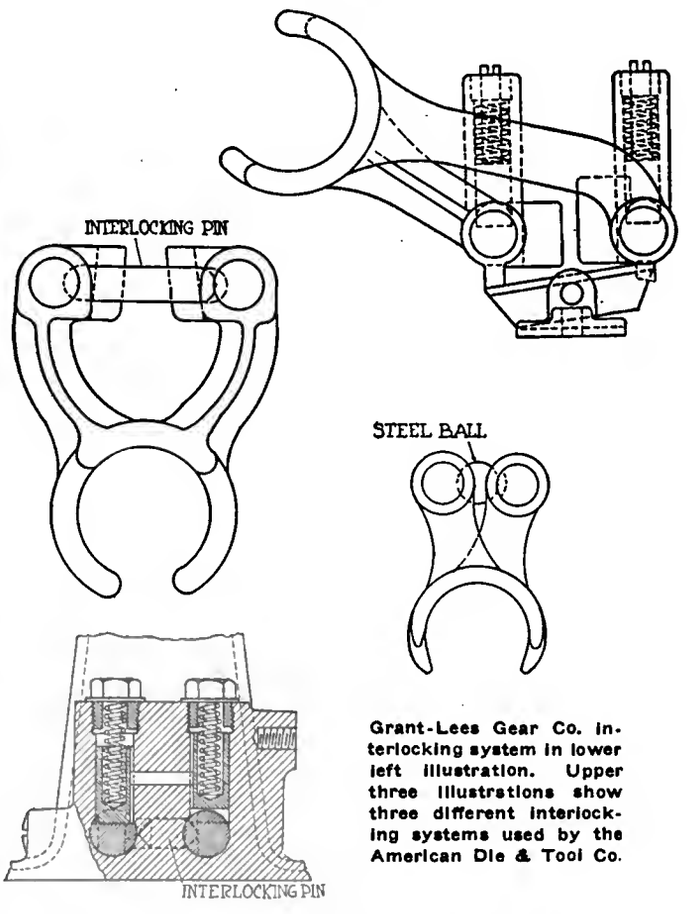


Northway gearset with main shaft on double annular ball bearings at one end and the short shaft at the opposite end supported on spiral roller with a similar bearing supporting the spigot. The clutch assembly is a cone type with small engagement springs regularly spaced. The countershaft is carried on plain bearings

is pressed into a notch in either fork when moved from neutral. Grant-Lees uses an interlocking pin fitting between the two pull rods, the grooves in which are deep enough to accommodate this pin in neutral position to allow either pull rod to move forward or back but the guide hole in the control housing prevents the other pull rod from moving while one rod is out of the neutral position, either forward or back. The pin is hardened and very little wear is said to take place in continual use. In a new constant mesh four-speed design which Cross Gear is bringing out for truck and bus work, there is a special locking device, which is said to be positive in its action. Two of the shifting fork shafts are held in neutral position by locking pins, which pass entirely through them, while the third shaft is shifted into the required position.

Gear Face and Pitch

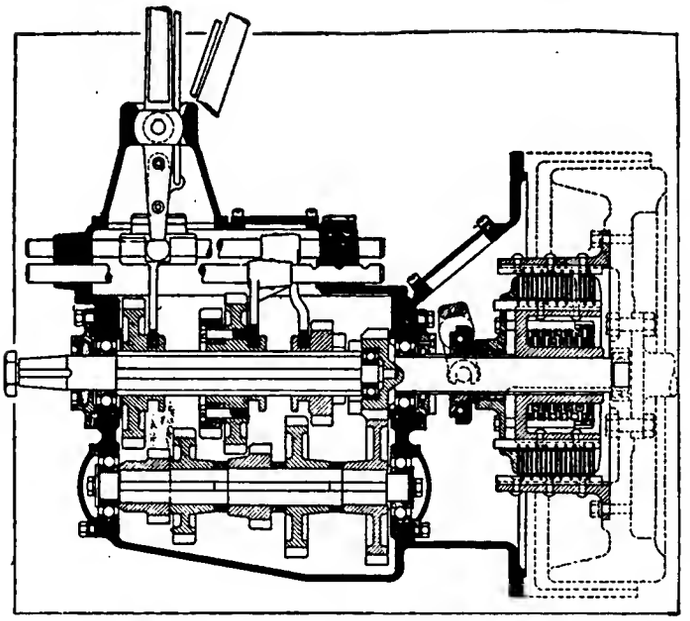
There seems to be a considerable difference among the gearset makers as to the quietest and most efficient types of gears in respect to pitch and width of face. Warner considers the finer pitch gears and those of narrower face as less likely to create noise, making the point that distortion is unavoidable during the hardening process as applied to wider gear faces. Brown-Lipe agrees in this contention but Grant-Lees considers stub toothed, coarse pitch gears more quiet in operation than gears of finer pitch of a given face. Thus for a ¾-in. face gear it finds a 6-8 pitch 20-deg. pressure angle has an advantage over 7-9 pitch 20-deg. pressure angle on account of less distortion in hardening although a coarser tooth 4-5 pitch would not be advisable for the same tooth width on account of the pitch diameters not allowing enough teeth to be in contact. The Mechanics Machine Co. does not believe that pitch and width of gear face have any great effect upon quietness but considers it inadvisable to make gears with less than thirteen teeth, counting on the care and manufacture to insure quiet operation. The American Die & Tool Co. reports that on various tests covering both 8-10 with 9/16-in. face gears and 6 and 6-8 with 1 in. and ⅞ in. face respectively, it has had both quiet and noisy operation.



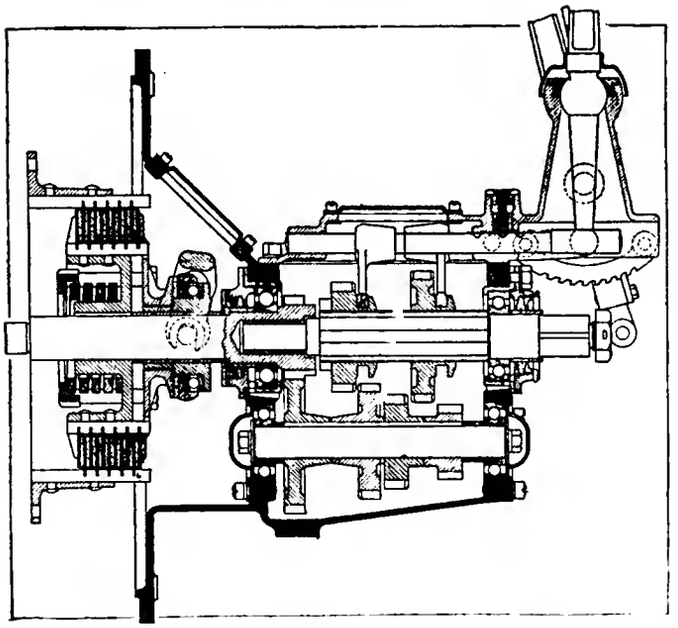
Grant-Lees Gear Co. interlocking system in lower left illustration. Upper three illustrations show three different interlocking systems used by the American Die & Tool Co.

It points out that the design in both cases has a bearing on the question, and when either of the sets is mounted in the cast iron housing even with ball bearings, noise has been a negligible factor. For standard practice this company considers the 6-8 pitch with the ⅞-in. face as most serviceable. Northway considers pitch, form of tooth and diameter important factors in securing a quiet gearset, the width of the gear face determining the duration of this quietness.

On the whole there is little tendency to make any change of the type or arrangement of bearings. Brown-Lipe uses

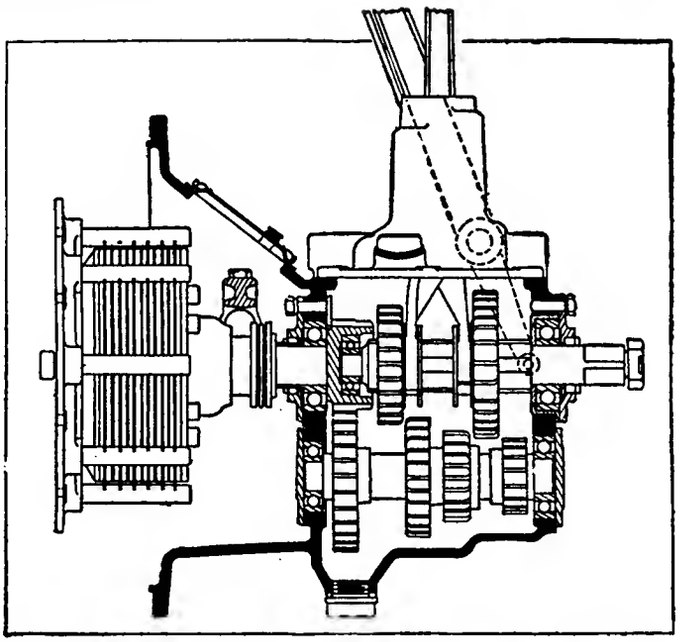


Muncie Gear Works vertical design gearset employing annular ball bearings throughout, including the spigot end of the main shaft. Gears are 5 pitch and ⅞ in. face. There is a ball thrust collar for clutch action and the clutch assembly of multiple disk type employs a double spring. The usual packings at each end of the main shaft are used to avoid leaking



Muncie Gear Works three-speed and reverse gearset using annular bearings throughout except at the spigot end of the main shaft, where a plain bearing is used. Gears are of 6-8 pitch. The main shaft is round section with four integral keys. Gears on the countershaft are held by keyway. The clutch assembly is inclosed within the usual flange construction

taper roller bearings throughout wherever possible in its standard constructions. Warner considers the use of either plain bushings or straight roller bearings within the countershaft gears and in connection with a stationary countershaft to be growing in favor. Northway finds a trend toward the adoption of spiral roller bearings type for the forward end of the main shaft and a double-row ball bearing in the rear. The American Die and Tool Co. has been using ball bearings throughout, its experiments with plain bearings on countershaft and spigot proving unsuccessful because of lubrication difficulties. For eliminating noise and reducing cost of manufacture this company recommends a combination of ball



Fuller & Sons Mfg. Co. gearset employing annular bearings throughout, including the ends of the spigot shaft. This unit assembly is made with flanges to fit all makes of motors

and roller bearings, or roller bearings throughout with a small roller bearing for the spigot.

Tire Pump and Speedometer Mounting

Provision for demounting of tire pump and speedometer is becoming more general with the gearset makers. With the Grant-Lees design the tire pump base can be bolted to the gearset housing and is driven off the reverse idler gear. Northway makes provision on the left side of the gearbox for the application of the tire pump, the drive being secured in the same manner as on the Grant-Lees. Similar constructions or their equivalents are to be found on practically all of the standard gearsets now being manufactured. Speedometer drives from the gearset are now largely inclosed, an example of this being the Northway, in which the speedometer drive is contained in the rear bearing retainer.

Ease of disassembly and assembly has been one of the important aims of the gearset designer for some time and during the past year a number of concerns have made slight improvements in this particular, one of the most salient of which is the practice of having all the parts assembled outside of the case so that they go in as a unit and may be removed in the same way. With the now almost universal central location for the gearshift and emergency brake levers, control members are neatly and conveniently mounted on the cover plate of the gearset housing, which still further simplifies the task of disassembly. Another factor in this situation and one which simplifies to a great extent the matter of replacements, not to mention its accompanying reduction of expense in case of repair, etc., is the increasing adoption of separate units in the gearset which can be easily removed. Thus in case of stripping the teeth of one gear or some similar mishap, the car owner is not obliged to replace a large part of his gearset at considerable expense, as was formerly the case with some constructions.

Differ on Lubrication

In the matter of lubrication there appears to be a wide diversity of opinion among the gearset manufacturers, both as to class of lubricant which is most desirable and the frequency with which it should be renewed. Brown-Lipe recommends extra heavy fluid oil filling the gearbox only to the top of the countershaft, stating that this will give sufficient lubrication for any emergency and will avoid leakage around the various joints of the gearbox, a condition which the company

states is almost invariably caused by high pressure due to heat expansion of the lubricant. This concern fits all its gearboxes with breather tubes to take care of this phase of the situation. Warner prefers transmission oils, stating that greases do not flow into the smaller spaces properly. This company has found that it secures best results with the oil depth about ½ in. from the top of the countershaft. Northway favors a fairly heavy grade of engine lubricating oil at a level about the center of the lower shaft. Manufacturers who do not agree with any of these views usually do not concern themselves with the matter, leaving the car builder to recommend whatever lubrication he considers best adapted for the gearset in its capacity as a unit of the chassis he is producing. On most of the modern gearsets oil level plugs are provided to determine the correct depth of the lubricant. Grant-Lees has changed from the gland stuffing box type to the spiral lead end plate, having found the latter superior in that it keeps the oil in the gearbox and requires no attention. The Cotta Transmission Co. recommends a medium light grease of a depth to cover both shafts of the gearset.

The majority of gearset makers agree that the lubricant, irrespective of the sort used, should be renewed every 5000 miles. Some, one of whom is Grant-Lees, consider that the lubricant should be examined once every 2 months with average driving, the frequency of renewing the lubricant depending upon how much the car is driven on its lower gears. Others, of whom Warner is an example, have secured best results when the lubricant is changed every 1200 to 1500 miles of car travel. When this lubricant is changed it is generally approved practice to drain out the lubricant thoroughly and then wash out the interior of the gearbox with kerosene oil.

Electric Gearshift Makes Progress

The use of electrically operated gearsets has made some progress during the past year, equipment of this type having been adopted as standard by a number of automobile companies, while several others have been conducting experiments with this method of control with a view to announcing it as standard or optional equipment about the first of the year.

For the future, little can be predicted as to probable alterations in the gearset and clutch design. It would seem most likely that present constructions will continue for some time without any appreciable change in their basic principles, the only alterations being in the way of refinements and simplification of parts or assembly and hence naturally of a minor nature. This state of affairs bids fair to endure until some radical developments in automobile construction call for correspondingly radical modification of gearsets and clutches as means for the transmission of power from engine to wheels.

Clutch Design Greatly Improved

Simplification Due to Elimination of Adjustments, Weight, Etc.—Disk Type Increasingly Popular—Fewer Plates Permit Increase of Pedal Leverage

By J. Edward Schipper

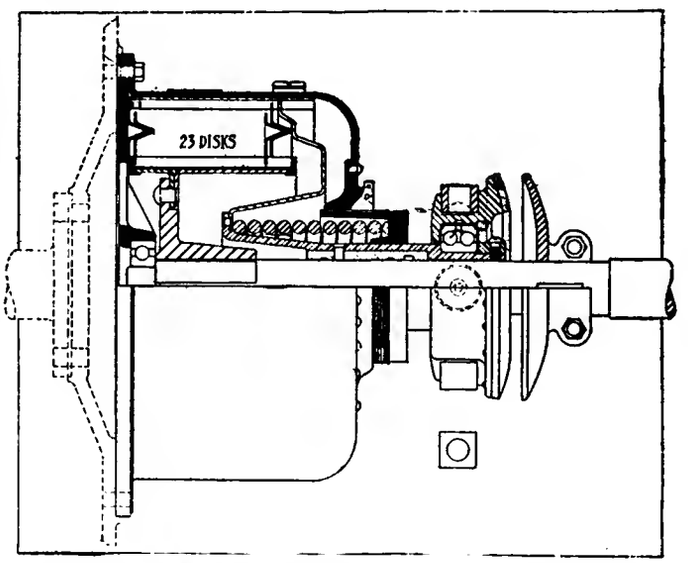
THE question of clutch design as shown by those clutch makers who supply to the automobile trade in general shows improvements from year to year. Elimination of adjustments and weight is the summation of clutch tendency in design as denoted by the changes during the past year. Broadly there is a tendency among the automobile manufacturers toward the employment of the disk rather than the cone. In the disk design itself there is a leaning toward the use of fewer disks.

If the figures on clutch weight per horsepower transmitted could be plotted in a curve they would show that this has been dropping, year by year. The aluminum cone for the cone type was one of the earlier indications of this and although the tendency is a little toward the pressed metal cone, the light-weight characteristic remains.

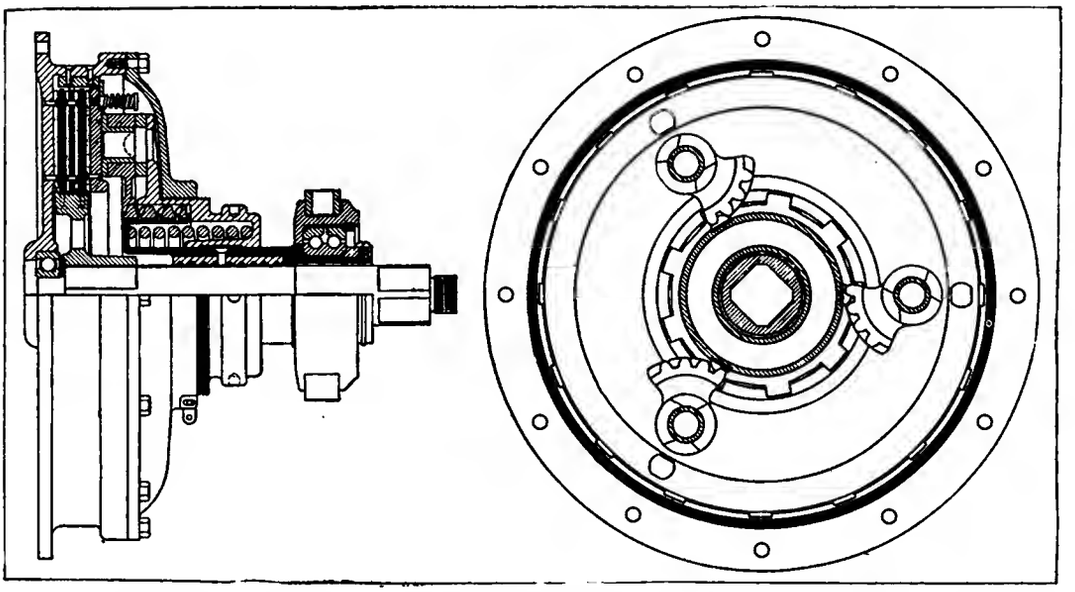
Lubrication Generally Automatic

Mechanically the clutch is a much simpler proposition now than heretofore. The adjustment points are fewer and the lubrication is generally automatic so that a clutch may go 50,000 miles without attention. Clutch wear is taken up automatically inside the assembly and on some of the prominent makes the only adjustment provided is that to prevent the pedal from striking the floorboard.

Another line of improvement is in the pedal linkage which permits clutch disengaged with much less effort. The leverage is increased in some instances directly on the pedal, but in general the reason for improvement is that the fewer plates on the disk clutch require less motion on the part of



Hele-Shaw standard No. 6 clutch with twenty-three disks for 40 hp. at 1000 r.p.m. This clutch is very widely used, being designed for flexibility and ease of operation in conjunction with positive engagement, insuring against loss of power in this unit of the transmission system. The case is of pressed steel, the core of steel and the presser is steel and malleable iron. Phosphor bronze is used for bushing and for the outer disk, the inner disk being sheet steel. The brake is of malleable iron with an asbestos lining

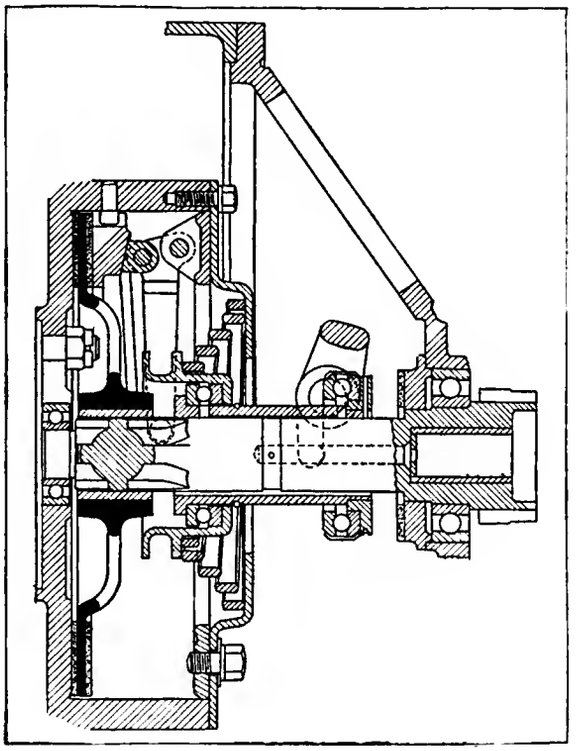


Hilliard Clutch & Machinery Co. disk clutch assembly with double annular bearing and inclosed spring. The forward end of the clutch shaft is supported within the flywheel disk by an annular ball bearing

the clutch linkage and hence it is possible to make this smaller travel up in increased pedal leverage.

The increased engine speed and greater reduction at the rear axle have influenced clutch design. It is naturally much more difficult to transmit in a given weight clutch, 40 hp. at 1200 r.p.m. than it is at 2500 r.p.m., the question being one of torque. With the greater rotative speeds of the clutch members, the torque transmitted at a given speed falls off and hence this will aid somewhat in clutch design, although factors of safety have increased rather than decreased, due to the use of better materials.

Lightness in clutch rotating parts is necessary if clashing of the gears is to be prevented. The clutch brake is an aid but independent of the clutch brake, makers have reduced the inertia and spinning tendency of the clutch members by a decrease in weight.



Borg & Beck clutch assembly showing three-plate clutch type with conical engagement spring and ball thrusts. The use of ball bearings is conspicuous in this clutch assembly

Ease of engagement is looked after in different ways in disk clutches, but with the cone, it is common practice to use about six bowshaped springs beneath the surface of the leather. On the clutch made by the Warner Gear company these are adjustable by means of screws on the inner side of the cone. There is no other adjustment.

With a ball-type thrust of two hardened and ground races of the best quality of material, and with the balls carried in a retainer that not only retains the balls but also a sufficient quantity of lubricant to take care of them readily, there is no need for an adjustment, as such an installation will serve indefinitely unless dirt or foreign matter enters. In that case, even an adjustment would not serve, as a replacement would have to be made anyway.

Cone clutch angles are about the same as formerly, running about 12 or 13 deg. Nothing has supplanted good quality leather as a facing for the cone. With the disk clutch the use of woven asbestos fabric quite similar to that used in brake installations is considered best by the majority. The leather is always riveted on with the rivets countersunk beneath the surface of the leather to secure against metal to metal engagement.

Engaged Area Decreasing

While with the disk clutch the total area of surface engaged is growing smaller, due to the falling off of the disk-in-oil type and the gaining of the dry-plate type, the trend is going the other way on the cone clutches. With the cone the surface area is less than the area given by the disk type, the difference being that it is more effective because applied at a greater distance from the axial center of rotation. The amount of clutch area in consideration for the work to be done, however, compares very favorably with the similar problem that comes up in brake design.

The Hilliard Clutch & Machinery Co. makes a feature of the point that no clutch brake is used. The spinning of the rotating members is prevented by simply having a combination of a quick-acting release which does not permit of a drag while releasing and further by having the parts so light, that the rotation does not continue long.

On the clutch made by Fuller & Sons Mfg. Co. the development has been typical in that all adjustments are eliminated. The clutch requires no attention except that the throwout bearing must be oiled occasionally. The only adjustment on the clutch is the adjustment which prevents the pedal from striking the floorboard. The clutch brake has been eliminated on all the Fuller clutches except the oil type, and in its place a quick releasing scheme with light parts has been substituted.

German Truck Design Is Improved

Commercial Vehicles Are Stronger But Lighter, Due to War Developments—Electric Types Gain—New Batteries Features—Gasoline the Fuel of the Army

By E. A. Langdon

WHILE passenger car design has made comparatively little progress in Germany since the outbreak of the war, motor truck construction has been greatly improved and the scope of both gasoline and electric commercial vehicles has been considerably widened. Strength and light weight are the features which most impress one in inspecting these machines, both being due to the need for economy in both construction and operation and to the use of lighter materials such as steel-reinforced wood frames, hydraulic spring systems instead of steel springs and other similar innovations.

Many Electric Trucks Used

The number of electric trucks has been greatly augmented, the ever-present necessity for economy being partially responsible for their popularity since current is unusually inexpensive, due to the abundance of coal Germany is mining from the northern section of France occupied by its armies. Highly efficient batteries of a new type have been developed because the demand for lead by the munitions factories rendered lead cells out of the question and the scarcity of nickel in Germany prevents the extensive use of the nickel-iron type. Gas batteries, in which slightly acid water is decomposed by the current on entering into oxygen and hydrogen, are said to be used in large numbers as reserve sources of current in stationary plants. When the oxygen and hydrogen is released from compression in the cathode and anode spaces through reduction valves they again combine as water, liberating current to the amount originally absorbed in the process of decomposition.

Gasoline Fuel for Army Cars

While gas obtained from distilled coal constitutes a large percentage of the automobile fuel used in the interior of the German Empire, gasoline is used almost entirely in military operations. The Germans consider their gasoline supply, at least sufficient for the needs of the army, to be secure for an indefinite period.

Material for spark plug terminals for a long time proved a stumbling block to German automobile engineers, as platinum is unobtainable. A new alloy has been developed, however, and is claimed to give very satisfactory results, although it has not yet had an opportunity to prove its serviceability in general use.

A Glass Cylinder Head

A number of interesting experiments have been made with new and unusual materials for automobile construction. One of the most novel of these was a cylinder head made of what looked like glass reinforced with wire fitted with valve seats of nickel steel. The material turned out to be an oxide of silica molded on a steel wire skeleton.

Wooden wheels are almost universally used on German cars and trucks, as the metal formerly employed in steel and wire types is now required for war purposes.

There are not many instances which illustrate so well the change industrial Germany has undergone during the last 2 years as the automobile situation in the interior of the empire. For life in general does not differ so very much from that in a normally operating country; the number of able-bodied men in the streets is considerably above what outsiders would imagine, and the people are fully as busy as in times of peace.

Few Passenger Cars on Streets

However, the moment one leaves a home, store or factory and enters the street, the abnormal condition of German existence becomes evident. For there is an absurdly small number of passenger automobiles, and what there are consist of old, invalid hacks, vehicles which nobody would think of using in normal times; and at the same time there is a very great number of commercial vehicles, but these, too, are of an entirely different type from what was seen before the outbreak of the war. Let us consider both of these phenomena.

All Good Cars Drafted

Passenger automobiles, like all things which are not a matter of absolute necessity, have become utterly negligible in German eyes—principally because they had to. The military operations at the front could easily employ all passenger automobiles German and Austrian factories could turn out, and more; and the absolute subjection of individual interests to those of the State has resulted in the drafting into service of every car which is at least 40 per cent efficient. These cars are used for the extremely rough work which frontal operations necessitate; and the result is that every part of the car suffers, though not in equal degree. Some of these machines, as has been described in a former article, are overhauled in field automobile hospitals, of which there are several at each front, and by this expedient the life of each car is increased, on an average, by 100 to 200 per cent. But finally the time arrives when the automobile can no longer be kept serviceable in this fashion, and when, in times of peace, it would be consigned without mercy to the junk heap. In war, however, the junk heap is merely the assorting department for the materials needed by the divers factories of the empire. Hence, these unserviceable automobiles are taken to one of the enormous plants handling this work of assorting waste materials—there are, in all, five such plants in Germany and Austria, employing in all close to 80,000 hands—where they are taken apart and segregated.

Some Parts Still Useful

Some parts of these disassembled cars with slight chemical treatment, can be used over in assembled cars which are continually being built for service at the front; other parts are put aside to be melted and entirely refashioned; whereas a minimum quantity of parts is always placed aside and used in the makeup of the passenger vehicles, police and ambulance wagons which are absolutely necessary in the interior. It stands to reason that these latter classes of vehicles are of a lamentable kind, most of the time entirely devoid of any

design, and built rather along lines of expediency than of harmony or looks.

Progress in Truck Design

As for trucks, the difference between the importance given to them and that allowed for pleasure cars is most striking. For commercial vehicles are not only, without exception, harmoniously and suitably designed, but every one gives a decided impression of strength, coupled with light weight. The latter point is the result of two conditions; first, the necessity of economizing all sources of energy; second, the use of lighter materials than were the vogue before the war. These lighter materials include spruce frames stayed by steel braces, as well as combinations with other principles of construction. It is surprising to an observer not accustomed to these types of vehicles what strength can be obtained by these means, if proper weight distribution is had by suitably designed braces and stays and if the suspension is ample. German engineers are not tempted to false economy in this latter regard.

Hydraulic Spring Systems

Hydraulic spring systems, often including a set of different-sized cylinders arranged in suitable series to take gradually varying shocks, have become very common during the last 2 years. Some of these hydraulic shock absorbers, which, by the way, have almost completely taken the place of steel springs on commercial vehicles, are not working on the principle of internal friction in the liquid or between the liquid and arduous passages, but are so constructed as to utilize the resistance of the container against an outward radial stress, whereby advantage is taken of the full tensile strength of the metal.

Electric Current Cheap

In regard to economy of energy—the word "fuel" being purposely avoided in this instance—the number of electric trucks has increased enormously ever since the outbreak of the war, and is still increasing, for all purposes where automobiles are used on good roads; and, generally speaking, all roads in the industrial sections of the empire *are* good. Electricity is one of those many commodities the productions of which is now under governmental supervision, but current is surprisingly cheap; the explanation being, very likely, that the Germans are deriving great quantities of coal from the mines in the territory held in France. In many cases, where numerous trucks travel along fixed lines of transportation, as between industrial centers of moderate distance—railroads being used chiefly for purely military passenger and freight transports—the vehicles are propelled by single or double electric motors in place on the rear axles, current being drawn from overhead conduits by means of a trolley. Where the importance of a route is not great enough to justify the construction of such a conduit-wire line—and it is remarkable with what degree of "scientific management" and statistical study the Germans determine whether a route is of greater or lesser national importance—the trucks are fitted with batteries. Very little can be learned just now about the construction of these batteries; but it is certain that almost all are other than lead cells, though it is not very likely that they are of the nickel-iron type, as nickel is quite rare in Germany at the present time.

New Type of Battery

Apropos of these conditions, it is interesting to note that a great many lead batteries which served as reserve sources of current in stationary plants have been supplanted by an entirely different type of battery, as lead is needed in the making of ammunition. These novel batteries are said, in a number of cases, to be of the "gas" type, wherein water with a slight acid percentage is decomposed by the current upon entering, is stored in cathode and anode spaces in form of oxygen and hydrogen, being compressed there by suitably designed mechanism, and when the battery is drawn upon, the gases leave from their chambers through reduction valves in proper proportions and again combine to water, freeing the amount of electricity first absorbed in the decomposition of the liquid.

Poles Faced with Platinum Powder

The poles of this battery are faced with "Platinmohr," black amorphous powder of platinum, which is at once a good conductor of electricity and a good catalyzing agent, being used to a great extent in the making of sulphuric acid, one of Germany's most important industries. The use of this material for batteries shows how the industries of the empire have become linked and, as it were, reshaped along lines of "interchangeability of parts." For the sulphuric-acid industry has been drawn upon for much of the platinum used there and is now using in place of the platinum method, a new kind of "contact process," as they call it. This is only another illustration of how, so to speak, not a molecule of matter is lost within the empire, no matter how great a quantity is shot and burned away at the battlefield.

Soldiers Understand Gasoline Cars

The fuel of the automobiles used at the front consists almost exclusively of gasoline, and the reason for this is that hundreds of thousands of soldiers are well familiar with the operation of gasoline engine and average automobile, as well as with the chief points of its construction; consequently the risk of the personal equation is smaller in the case of the average gasoline car than if any other type of automobile were used. Moreover, the Austrian oil fields in Poland, the wells of the occupied Russian territory and what oil and oil products were imported from Rumania heretofore are ample for the requirements of the field automobiles, and the more perfect organization developed during the war has quite overcome the need of using industrial alcohol, or benzol, for that matter. At the time of this writing, it is a few days since Rumania has entered the war, and according to the military experts who predicted with fair precision the development of the Serbian campaign under General Mackensen, the Germans expect to be in secure possession of the Rumanian oil fields within less than 8 weeks. This, of course, is problematical, but the fact is that even if the Rumanian supplies of gasoline to Germany be cut off, the other two sources mentioned would suffice for the needs of the army—and navy, for the latter now includes a number of vessels, both of the submarine and light cruiser type, using kerosene or gasoline for propulsion.

Material for Plug Terminals

One of the difficulties experienced by German engineers lies in the terminals of spark plugs. Platinum, used solid or as a coat, is absolutely unobtainable, as Russia, the chief former source of supply, is now of course shut off, save for small quantities which find their way into Germany via Sweden, or which were taken from craft captured in the Baltic. The Germans have been working on an "Ersatz" (substitute) for some time, and while it is not used generally as yet, engineers claim to obtain surprisingly fair results therefrom. They are, of course, very secretive about the matter; but from what the writer could learn, in a vague manner, here and there, it would seem that the substitute is an alloy of gold and a metal of the "radium" group, very likely uranium. Some experiments made with a selenium compound or rather alloy are also said to have been fairly satisfactory, except for the variable conductivity of this element which changes with the degree of light or radiation to which it is exposed; which fact caused fluctuations and disturbances throughout the ignition system of the car and

led to the abandoning of the idea as hardly practicable.

One peculiar innovation was witnessed by me some time ago when visiting the Western front. It was a cylinder head made of a material which resembled wire-reinforced glass, and, it was stated, was indeed of a similar composition, namely, an oxide of silica made in one of the chemical factories along the Main and reinforced by a skeleton of steel wire. The valve seats, made of nickel steel, are put in place when the head is being made and still at a very high temperature. These cylinder heads are, except for the connecting ways to the manifolds, without jackets; small wire points protrude from the inner wire skeleton and are cooled by the stream of air directed upward by the inclined fan.

Wood Wheels Employed

While the French and English armies use thousands of cars fitted with wire wheels, the Germans have practically departed from their use, principally because the empire's enormous lumber reserves permit of easy and cheap wholesale production of good wooden wheels, while every metal is comparatively scarce and economy is necessary. The metal which has been less subject to this rule than any other seems to be aluminum, for which new uses are found every day and which is produced very cheaply by the electric furnace process.

Thermite Welding Process Important

The aluminum powder, or Thermite, process of welding has also become of tremendous importance, and the equipment for this process forms part of every "Automobil-Hilfe-Automobil," that is, an automobile containing the repairshop equipment needed for quick repairs of automobiles and motor trucks. These traveling "Automobillazaretts" contain a simple but complete outfit for welding, a lathe, punch, a small drop forge, and a full set of minor tools, so that almost any repair can be made anywhere and at any time, the necessary power being furnished by the motor of the repair wagon. These traveling repairshops are, morever, fitted with wireless telephones and small generators geared to their motors, so that they can easily and immediately get into communication with the nearest motor department, "Kraftwagenfluegel," of the army to which they belong. The crew consists of three men, each one an expert driver and mechanic and electrician.

Young Drivers Well Trained

Every kind of labor which is connected with the driving and repairing of automobiles is plentifully supplied to the army. The boys between 17 and 19 years of age are trained in the school, with a view to preparing them for military service when they reach the full age, and from among those showing mechanical ability and inclination the future automobile operators are picked. These are trained by experts, not only in driving, but in repairing every conceivable kind of accident or damage, as well as first aid to the injured; so that in all likelihood Germany will possess, when the war is over, the greatest number of automobile expert drivers among all countries in Europe, which will make these young men vastly superior in earning power and serviceableness to what they would have been without this training.

Automobile Corps of High Class

Wherever possible, the automobile drivers are chosen from the soldiers knowing the language of the enemy the particular army is in contact with, so that if by accident they come into possession of military information they are in a position to report it with the greatest possible speed to their superiors. A stranger would be most surprised to note the high percentage of intellectual men, engineers as well as students of medicine, languages and theology, among the contingent of automobiles attached to the German army.

Spring Starters Widely Used

While the construction of automobiles, as heretofore mentioned, has become much simpler, no desirable accessories are spared to make operation efficient. For instance, spring types of self-starters are almost universally used where hand cranking is not retained; and speedometer, thermometer and barometer form part of every automobile equipment; the same thing may be said to hold true of the "trench periscope," a vertical tube with inclined mirrors at each end, and about 6 ft. long; a small heliograph, detailed map, compass, etc.

A Big Tractor Market

There is no doubt that when the war will be over, the automobile industry of Germany will emerge as something reborn and as far advanced over what it was before July 31, 1914, as it was at the latter date over 1900, both because of the improvements and developments made during the war, and on account of the practical annihilation of most draft animals, except what specimens were reserved for stock breeding. But there is little likelihood of the German peasant ever turning to horses again for his agricultural work. What he will look for, will be a moderately priced, highly reliable, simple, efficient automobile, which can be rapidly transformed into a tractor. For such a machine, Germany will offer a wonderful market, because, in spite of the empire's enormous industry, agriculture is still one of the two greatest, if not the greatest method of occupation of the German people.

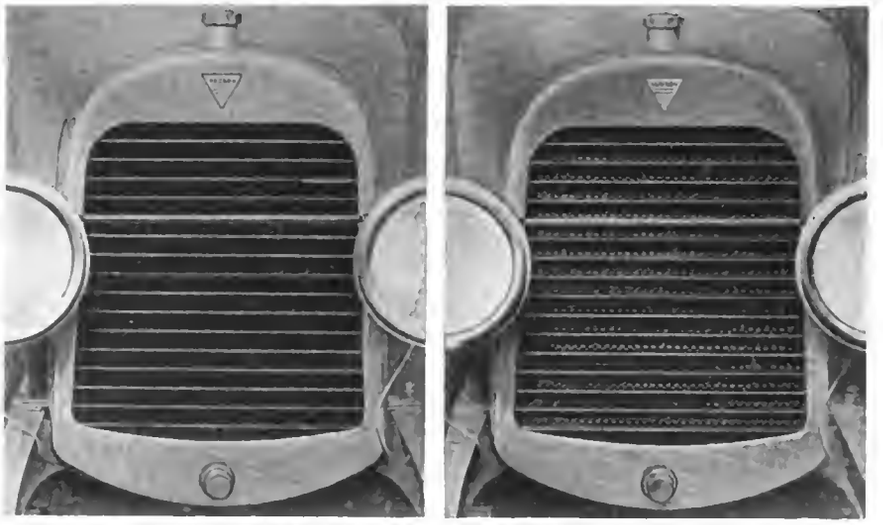
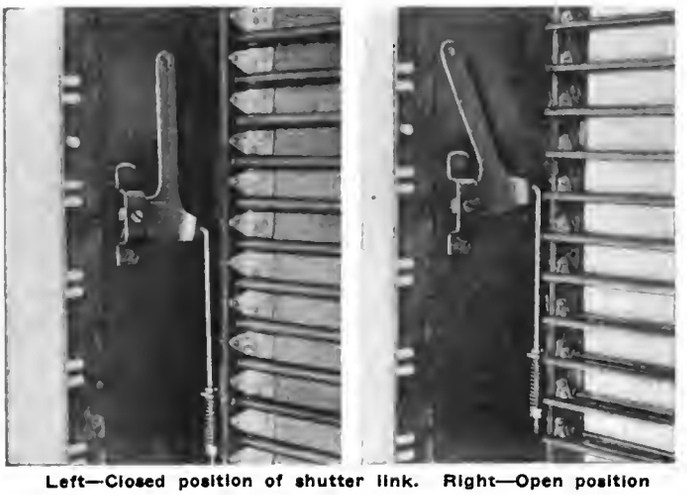
Hudson Fits Dash Radiator Control

Illustrating operation of the Hudson radiator shutter control by means of pull rod from the dash



At the left is a view of the Hudson radiator with the shutter closed and at the right with the shutter partly open



Left—Closed position of shutter link. Right—Open position

TO remove the necessity for using padded covers. etc., on the radiators of Hudson cars, the company has brought out a device which acts as a radiator shutter and which is being listed as special equipment. The new device is operated from the dash by the driver and permits him, by means of a simple plunger, to govern the amount of air that comes in contact with the radiating surface, and hence puts the temperature of the cooling fluid under his control.

The device acts very much as a shutter, with a series of vanes which open and close in accordance with the movement of the controlling device on the dash. In summer the mechanism need not be detached, as it does not cut down materially the area of the radiator when it is full open, so that in warm weather it is simply left untouched.

In order that the device will be complete, it is necessary for the driver to know the temperature of the cooling water accurately enough to determine whether the shutter is open or closed to the correct degree. This part of the equipment is provided by a Boyce Moto-Meter mounted in its customary position on the radiator cap.

The device is valuable in warming the car in very cold weather, as the air can be entirely shut off from the radiator until the water temperature reaches its efficient temperature, which in the case of the Hudson is stated to be 130 deg. Fahr. The shutter vanes can then be opened to the desired amount by simply operating the pull-rod on the dash.

From a maintenance standpoint the device is simple, as there is nothing to it except the shutter and the rod and bell-crank operating mechanism. There is no need for any adjustments, and none is provided. The installation is simple, and is made possible by using a longer radiator shell which not only houses the radiator, but also the shutter. It can be fitted to all Super-six Hudsons, the cost of installation being $25, with Moto-Meter complete. If the owner has already a Moto-Meter the shutter assembly costs only $15.

The accompanying illustrations give a very clear idea of the construction and operation of the device, the neat and simple pull rod mounting on the dash being both conveniently situated and by no means detrimental to the appearance of the instrument board. The front views of the radiator showing the shutter both closed and in a partly open position make it evident that appearance has not suffered in this direction; in fact, if any comment is to be made on the matter, it may be said that the new design is more attractive than the old and far less likely to become clogged with dust and debris from the road.

—

Goodyear Employees Paid for Ideas

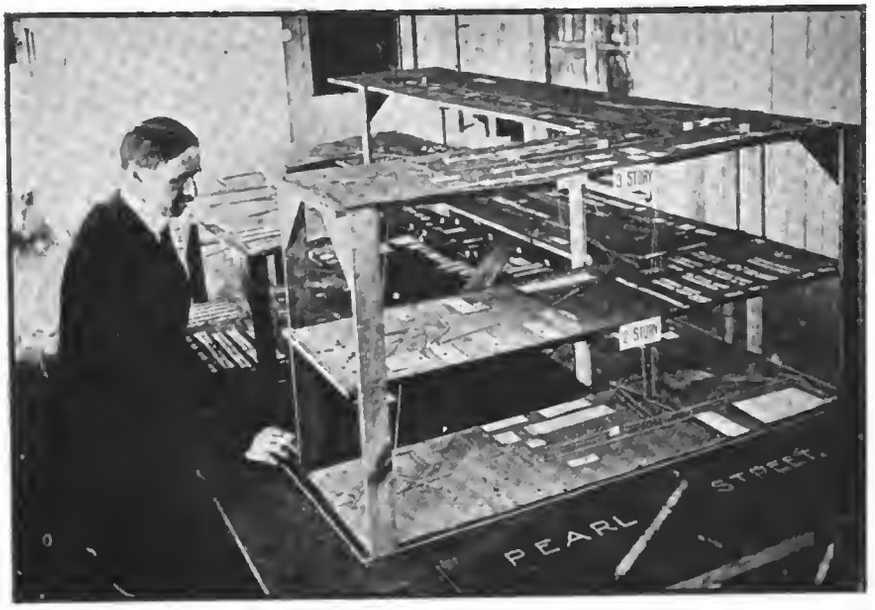
ONE of the most popular operative features at the plant of The Goodyear Tire & Rubber Co., Akron, Ohio, is the suggestion system, which enables employees to capitalize their ideas for improving machinery, conditions, methods and product.

The workmen who make Goodyear products are given every opportunity to advance their ideas, and all suggestions adopted are well paid for. Interest in the system is well sustained, and thousands of dollars have been paid to employees for their ideas.

The suggestion box method is used, with boxes placed throughout the plant in convenient places. Employees are asked to put their ideas in writing and deposit them in the suggestion box. The suggestions are gathered each day and referred to the proper persons for consideration. All are carefully gone over, however inconsequential they may seem.

Motion Study as a Production Factor

Examining the Worker's Motions To Ascertain Causes for Inefficiency—Frank B. Gilbreth's Methods and Instruments



Model of factory as laid out before plans for analysis are made to determine lost motion

DOES the average worker become fatigued unnecessarily? Is the production of the usual factory below its capacity? Are many factories increasing the number of men and the amount of floorspace needlessly? Is it possible for the average workman to be raised to a higher level of efficiency, raising his productive abilities, yet lowering his fatigue? Do wasted motion and wasted effort cause a vast loss of wasted time to the majority of manufacturers? These interesting and vitally important questions form a great part in the study of motion that Frank B. Gilbreth, efficiency engineer of Providence, R. I., has made a life problem and to which he introduced many novel and consequential theories and devices.

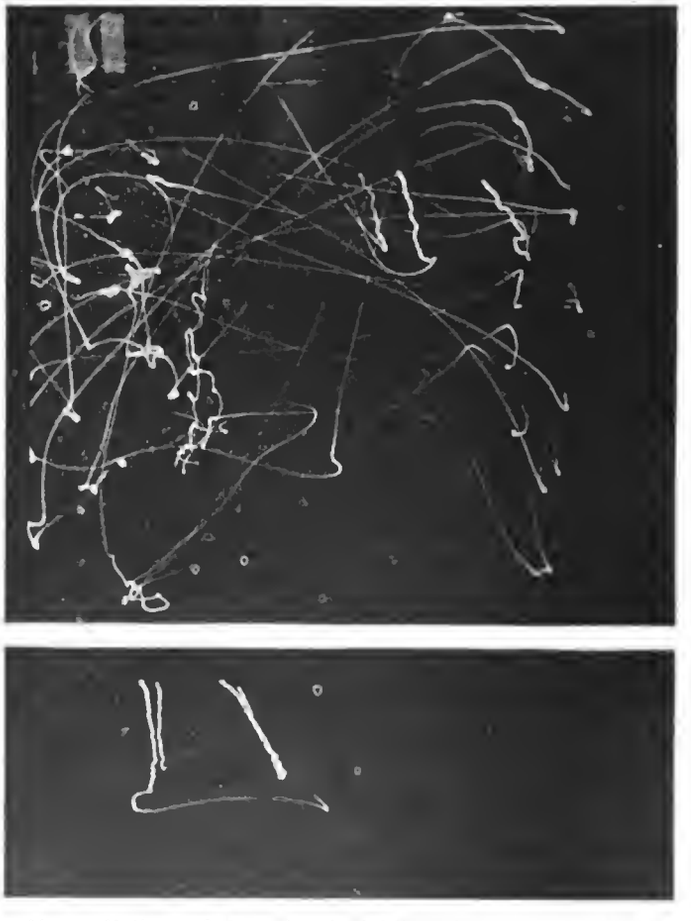
Wasted Energy

Thirty years ago Mr. Gilbreth was an apprentice bricklayer. He asked the foreman to show him the proper way to lay bricks. Though a master mason, the foreman had many methods. One was for hurried labor, another for times when speed was not required and so forth. The boy studied the work thoroughly. He saw that many of the men, like the foreman, never laid the bricks with the same motions for two jobs. He became convinced that a very valuable study would be found in an attempt to determine the least number of motions for brick laying that would at the same time have the effect of not tiring the worker. Since that time he has devoted himself to efficiency, first as a student, and now as a consulting engineer confining his time to the discovery of waste motion in various factories and industries.

He investigates factories, makes improvements, omits stages of manufacture and substitutes skilled labor for unskilled wherever possible. In a handkerchief factory he noticed one girl whose work, consisting of folding handkerchiefs, slackened perceptibly each afternoon until it fell far below the work of the others. Investigation revealed that the chair upon which the girl sat had worn, that the front legs were so low that the girl was forced to use her arms at so high an angle that they tired and consequently became less efficient. A carpenter repaired the chair and a few days sufficed to show the girl working with all the speed of her companions in the shop.

Motion Study a Science

Mr. Gilbreth defines his work as motion study and says: "Motion study is the science of determining methods of least waste and my work is the installation of laboratories for large concerns and the creation of examining processes to determine how the work can be done with the least number of movements. The discovery of such a method allows the manufacturer to secure the greatest possible output, to pay his employees more money and to make more money for himself." He believes that

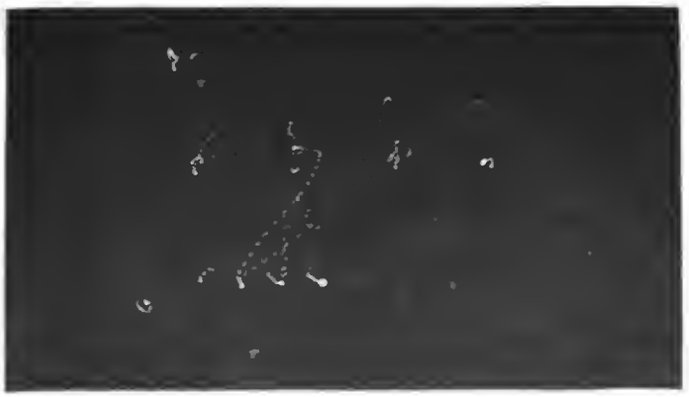


Above—Motions of a worker in loading sixteen boxes before motion study methods were adopted. Below—The same operation when efficient methods of concentrated motion are used

Right—Foremen of a factory being instructed in the wrong and right methods of operation by means of moving picture application of motion study

Below—Cross section method of studying motion to eliminate fatigue, the worker standing before a background of checks, so that each motion can be recorded according to its appearance before the squares

Lamp used with cinematograph to display the motions of the worker. Lamps are attached to fingers, knees or forehead



Hand of a bricklayer photographed with lamp attached and showing the operation of laying bricks when motion study methods minimize the expenditure of effort

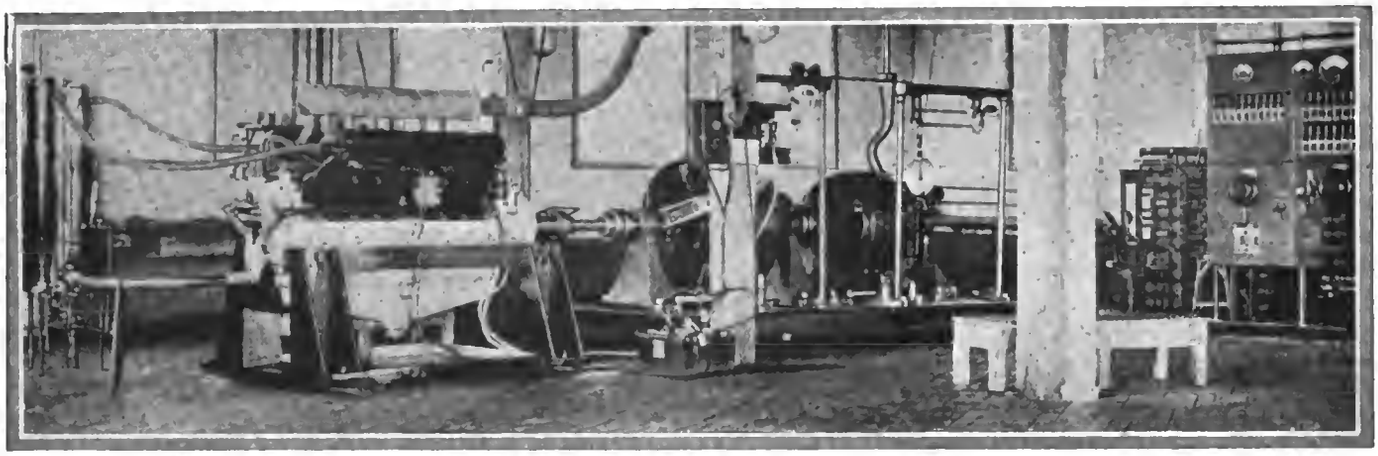
the only way to study an industry or trade is to learn the fundamental motions and to do these rapidly even though the speed, at first, affects the quality as he finds that the elimination of unnecessary motion is more important than spending time learning the process by slow and elaborate methods. The slow way, he states, requires far different motions from the quickest way and as a consequence, the worker is forced to learn two methods before he becomes proficient.

To ascertain the motions of workers, Mr. Gilbreth has utilized and invented many instruments. He commenced his work with a stop watch but found it too slow and often inaccurate and has combined with it the cinematograph, which is able to photograph every motion and preserve it and, in addition, when used with a special clock, allows him to time each movement. The clock is an appliance that makes a complete revolution every 3 sec. and measures to the millionth part of an hour. It has a watch attachment to check its accuracy. Temperature and humidity are always taken into consideration. A penetrating screen is used on which the proper motions are marked and before which a photograph of the worker is taken so that his movements can be compared with the correct ones. Thus, by means of the moving pictures and the screen, the worker not only sees himself as others see him but also is able to witness many movements not ordinarily seen by the eye and is shown all of the wasted effort he has used.

Lights Show Motions

To facilitate the camera, lights, similar to those used by physicians for examination of the throat and operated by a make and break apparatus, are used. They are placed upon the hands, fingers, knees and foreheads of workers and photographs taken reveal each movement of the various lamps. The photography is consequently utilized to determine time when compared with the clock and the flashing lamps, and to discover the width, length and breadth of the motion of the worker. Complete assembly operations are often photographed and each movement required by the different workers is displayed and timed and measured. The work of the best men can thus be shown on a slow moving cinematograph machine so that it can be followed by the unskilled and adopted by them.

Another instrument used is a background of checks against which the worker stands and moves so that each motion can be recorded according to its appearance before the squares. Utilizing this system, Mr. Gilbreth checked a man loading boxes. He classified his motions by sixteen acts under the headings of search, find, select, grasp, position, assemble, use, disassemble, inspect, loaded, position for next operation, relieve load, transport empty, wait unavoidable, wait avoidable and rest. The results of these checks are shown in the two illustrations at the bottom of the opposite page.



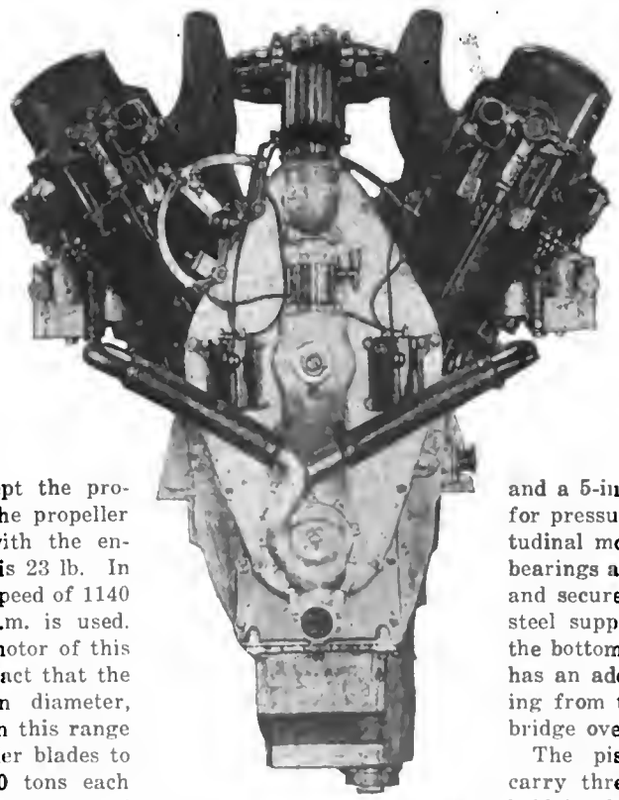
Knox twelve-cylinder aviation engine designed by F. H. Trego undergoing tests with a Sprague dynamometer at the Knox laboratory

Knox Aviation Twelve Tested

300-Hp. Engine Designed by F. H. Trego Has 4 3/4 by 7 In. Bore and Stroke—8-Hr. Run Made

SPRINGFIELD, Mass. Nov. 15—One of the largest V-type aviation engines ever built in this country has just been put through a series of tests in the laboratory of the Knox Motors Co. here by Frank H. Trego, chief engineer and designer of the motor. The engine is intended for high-power aviation work and is rated at 300 hp. It has been designed to meet the severest aeroplane service in Europe, and since work was started on it a year ago representatives of foreign concerns have not only been watching its development but keeping very closely in touch with all engineering details. Engineer Trego has been working on the matter consistently for nearly a year and has now a power plant capable of withstanding the severity of 8-hr. tests.

The engine, a twelve-cylinder, V-type valve-in-the-head design, has the aluminum cylinder blocks formed in groups of three, and the two sets of threes mounted at 60 deg. to each other. The bore and stroke of 4¾ and 7 give a piston displacement of 1488.53 cu. in. With this piston displacement the weight complete with starting and lighting motor and generator, ignition equipment, exhaust pipes, and tachometer is 1400 lb. This weight includes everything except the propeller hub, which is a part of the propeller assembly, although furnished with the engine. The propeller hub weight is 23 lb. In the preliminary test a propeller speed of 1140 and a motor speed of 1600 r.p.m. is used. Some conception of the work a motor of this type has to do is shown by the fact that the four-bladed propeller, 14 ft. in diameter, turns at 1100 to 1200 r. p. m. In this range of speed the effort of the propeller blades to fly off the hub approximates 20 tons each and the propeller has a pushing power of 2000 lb., according to Engineer Trego.



End view of the new twelve-cylinder Knox aviation engine

The cylinder blocks are aluminum castings open at each end and in these are pressed ⅛-in. cast iron liners, these liners having a flange on the lower end are pressed into the bottom. Although the cylinders are cast in blocks of three, the heads are cast in blocks of six and are of aluminum alloy with cast iron valve seats, cast integrally with head casting. The head for each of the cylinders is secured by sixteen nickel steel studs passing through the head. The four valves in each cylinder are carried in the head and the water-jacketing so arranged as to surround each valve seat. The water-jacketing of the cylinder blocks is so carried out as to extend below the bottom of the stroke and to allow ½-in. water space between adjacent cylinders. In addition each cylinder head has an aluminum cover which entirely conceals and protects all of the valve mechanisms.

The rotating and reciprocating parts of the engine have been designed with the thought of enduring the heaviest service imposed on an aviation motor. The crankshaft, a chrome nickel steel forging, is 3 in. in diameter at its three bearings as well as at the crankpins. The shaft has a total bearing length of 13 in., 4 in. at the front and center, and a 5-in. bearing at the rear. It is drilled for pressure lubrication and held from longitudinal movement by a center bearing. The bearings are babbitt, backed by a bronze shell and secured by aluminum caps backed up by steel supporting plates ⅝ in. thick all over the bottom of the bearing. The rear bearing has an additional supporting steel bar hanging from two bolts which pass down from a bridge over the top of the crankcase.

The pistons of special aluminum alloy carry three rings and have the piston pin held in the upper end of the connecting-rod with its bearing in the piston where the

aluminum alloy serves as a bearing metal.

Connecting-rods are drop forgings with a bearing cap at the lower end held by two bolts and with cap and rod locked together by tongue-and-groove formation to prevent twisting The rods are side by side on each crank throw.

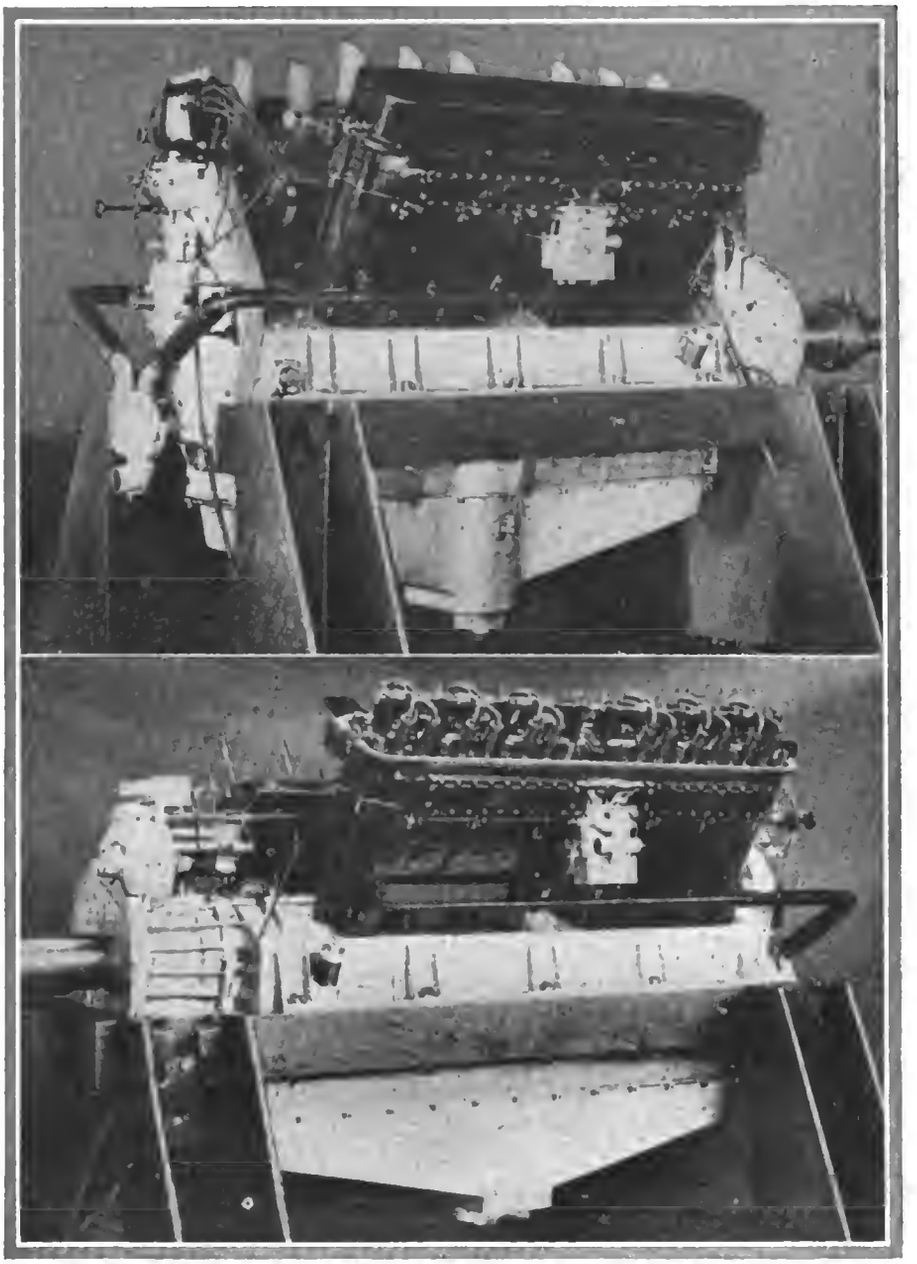
The crankcase is an aluminum alloy formed in one piece and extending 7 in. below the center lines of crankshaft in order to give a barrel section for strength. The lower half is a one-piece aluminum casting bolting to the upper half and not containing any of the motor mechanism.

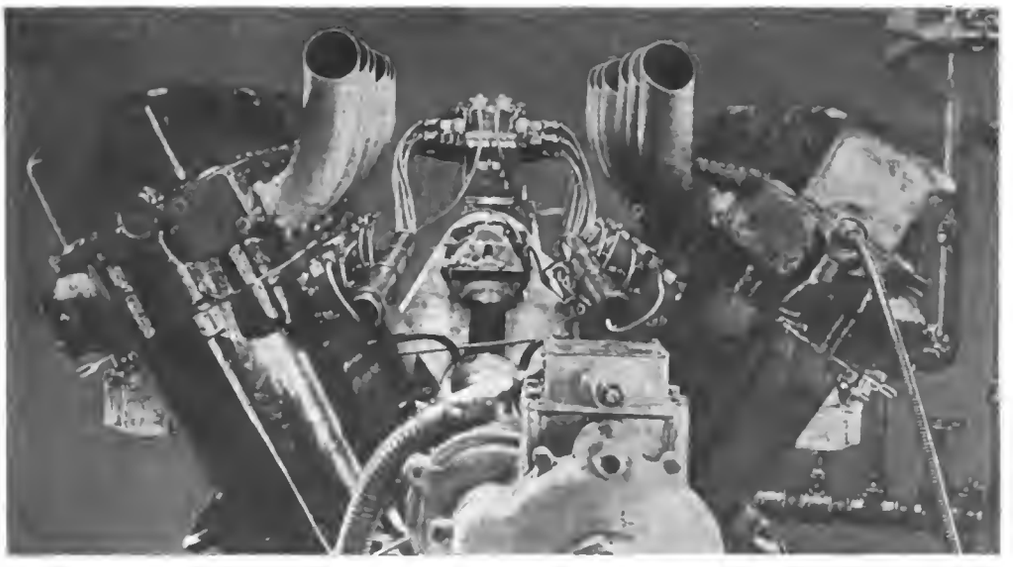
For attachment into the framework of the aeroplane supporting legs are not used but support is through a shelf extending the full length of the crankcase on each side and on which the motor rests. Five bolts anchor each shelf into the framework of the aeroplane and to add rigidity a rib is cast on each side of each bolt. With this support the motor is kept very narrow at this point and rests in a frame 15 in. wide inside and with bolt centers 17 in. apart.

Valves at an Angle

The valve mechanism operating four valves in each cylinder is operated through a camshaft lying along the head of each cylinder block, thus mounting the valves at a slight angle to the cylinder bore. The camshaft and rocker arms are supported in the head, the camshaft having eight bearings. The arc-shaped rocker arms are supported above it as the end section shows. Forced feed lubrication with necessary drainage back to the crankcase is at the center of the motor when the motor is in normal condition and at each end when the motor tips up or down.

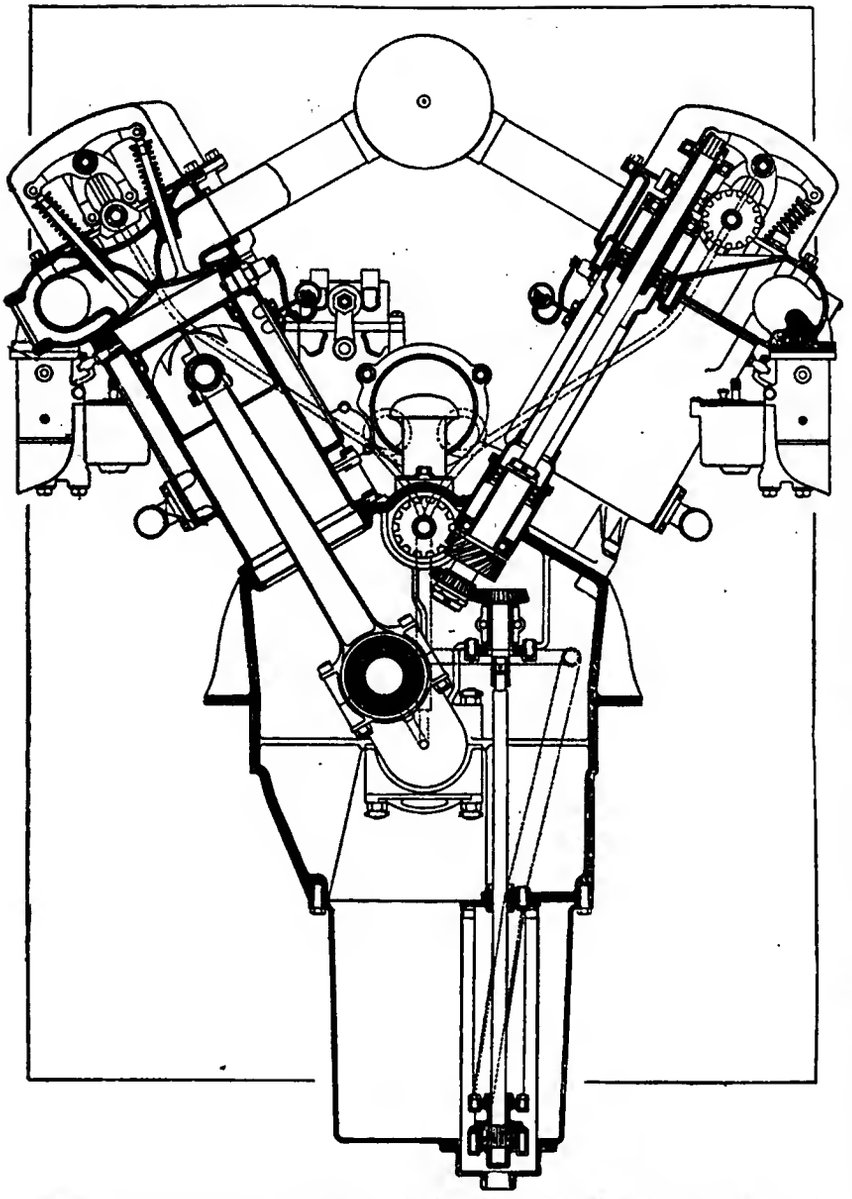
On one end of the engine is an





Above — Both sides of the Knox aviation engine, the upper one showing the arrangement of the ignition and water pump below. The lower picture shows the starting motor with its switch mounted immediately above a casing which contains the reduction gear for driving the propeller

Left—Looking along the V space between the cylinders showing the open exhausts, central location of the ignition unit and starting motor switch in front



Section through the Knox twelve-cylinder 4¾ by 7 in. aviation engine, showing the camshaft drive for the overhead valve rockers. The pump drive is also shown

aluminum housing for the timing gears and the support of the water pump, air pump, ignition apparatus and lighting generator.

On the other end of the motor is a heavy special aluminum casting to support the propeller shaft with its bearings in which the ball bearing holes are lined with steel bushing to prevent wearing the aluminum. This casting with its cover provides for the large starting gear on the propeller shaft as well as for supports for the starting motor, switch, etc.

Drive of Engine Accessories

The method of driving the different motor accessories is through a longitudinal drive shaft above the crankshaft and driven by the timing gears. This drive shaft has two integral spiral gears which are at the center of the motor for driving two vertical shafts, which extend up through tubes into the cylinder heads and on through short hollow shafts. Each vertical shaft terminates in a splined end with a splined cap piece which bolts to the short hollow shaft. This arrangement permits of changing the relationship of the camshaft to the vertical shaft for valve timing. The oil drainage from the cylinder head passes down through the ball bearings on the vertical shaft and thence through the tubes to the crankcase.

Motor lubrication embraces all of the moving parts of the engine. Oil flow originates in a pump supported from the upper half of the crankcase so that there is no pump connection between the pump and the motor. Steel pipes cast integrally with the crankcase register with the oil pump to make the necessary connections. Oil holes drilled in the case for lubrication are lined with steel tubes to insure against leakage. The main oil lead extends the entire length of the crankcase and has holes drilled to the crankshaft bearings, these also being steel lined.

The oil is taken in the crankshaft bearing at the timing gear and led to the horizontal driveshaft bearing immediately above it, and thence is led through the hollow driveshaft to the center or either end of the shaft, whence it flows through copper tubes to the cylinder heads. In each head it passes through the camshaft supporting brackets into the hollow camshaft, thence to all its bearings and to the hollow rocker arm shafts and to each rocker arm. The result of this oil circulation is that valve-stems, springs, rocker arms, rollers, camshafts and other moving parts are saturated at all times.

Timing gears are oiled by the throw-off of the crankshaft bearing at that end. The propeller gears are oiled in the same manner at the other end. Oil pressure is from 40 to 70 lb., there being an adjustable regulator on the side of the tank. A large oil screen is carried in the lower half of the crankcase and covers the oil pump clear up to the upper half of the case. This screen may be withdrawn for cleaning without disturbing any mechanism. On the outside of the crankcase is an oil gage.

Double Zenith carbureters are placed in each side of the engine, outside of the cylinder blocks, thus using a separate carbureter for each three cylinders. There is nothing on the outside of the engine excepting these carbureters; and there is nothing in the V between the blocks excepting the two breathers rising from the top of the crankcase.

The electric starting motor and the lighting generator are built into the engine, the former so that starting is by pressing a button which throws the switch.

Ignition is by battery type with the current furnished by a battery for starting, but with the running current from the generator. There is one spark plug in each cylinder. All six priming cocks on each side of the motor can be operated at once by a pull-handle. Gasoline feed is by pressure furnished by a two-cycle type of air pump furnishing pressure of 4 to 7 lb. An adjustable regulator is attached.

The water pump, a double impeller type, with water on each side of the impeller to avoid thrust, is made in one assembly and driven through a flexible coupling at the end of the crankshaft. The pump has one intake and two discharge pipes, which lead to brass taper tubes extending alongside of the engine on either side, and supplying the cylinder blocks with water at two points each. The water rises through the cylinder jackets, passing directly into the heads through registering holes and flows out at either end of the heads as desired.

The propeller shaft is supported on a heavy double-row, self-aligning, ball bearing, with a thrust taken in either direction by a double ball thrust, with a load capacity of 2650 lb. in either direction. The propeller shaft is 3⅝ in.

Princess four-cylinder, five-passenger touring car, which sells for $775, including complete equipment

1917 Princess Is Larger

Wheelbase Increased 4 in.—Rear Axle Now Floating—Two-Unit Electric System

FOR 1917 the Princess Motor Car Corp. of Detroit is presenting a very much refined product as compared with the previous model. The factory is now pushing production and deliveries.

The car is larger, roomier and better equipped. The wheelbase has been increased from 104 to 108 in. the additional 4 in. being used for body space. This is the main factor in making the car larger and the difference is immediately apparent when last year's car and this year's are side by side.

Floating Rear Axle

In addition there have been numerous mechanical alterations. The rear axle design is entirely different, being floating instead of semi-floating. The starting and lighting system is a two-unit device instead of a single-unit one. It is Disco, as formerly. With the new installation a Bendix gear is used for the starting motor whereas the motor-generator outfiit previously used had a silent chain reduction of 3 to 1.

To take care of the larger car, bigger brakes are installed. they are 12 by 2¼ in., instead of 12 by 1¾. The tires are larger, being 32 by 3½ instead of 30 by 3½.

In the engine no changes of importance are made although there are perhaps a dozen alterations of minor consequence. The position of the magneto is new, and the oiling system changed in detail. This is a detachable head unit.

The speedometer drive is from the transmission gears. Appearance has also been given attention in other details, particularly in the overhauling of the fenders and running boards. The running boards are now linoleum on wood, aluminum-bound, instead of aluminum on sheet metal. This is better construction right through, and besides being more sightly it is also stronger and does away with rattles. The front fenders are so formed that they are virtually sill boards also, this removes all the cracks and prevents the entrance of any dirt or water.

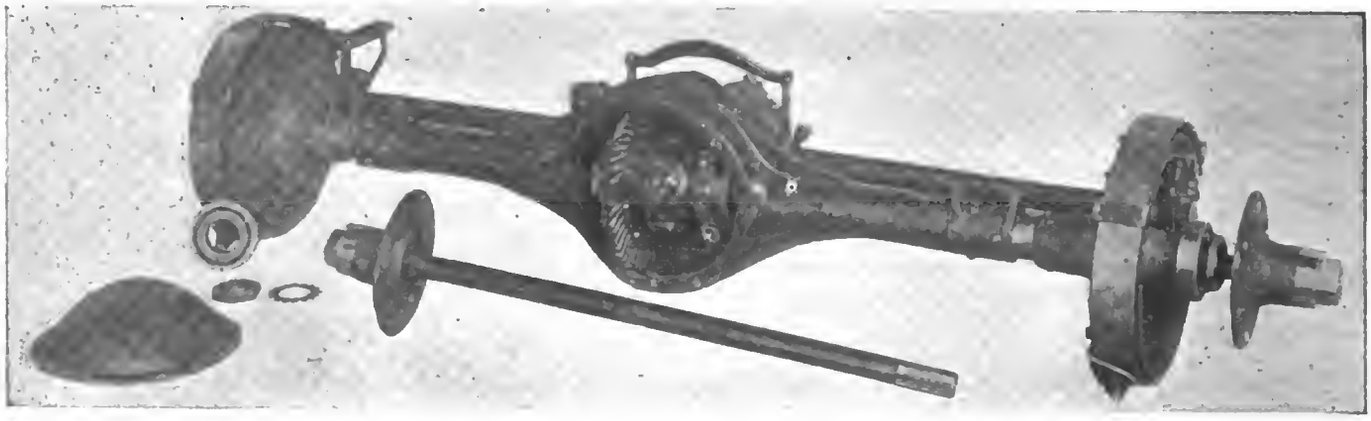
A sloping windshield instead of a vertical one makes not only for appearance but also for strength in taking the strains imposed by the one-person top. The side curtains are now easier to adjust.

On the instrument board the Van Sicklen speedometer, speedometer light, ammeter, oil gage, King lock, and fuse box with spring-attached cover, are grouped integrally. By taking out four screws the entire instrument assembly can be lifted out for repair or inspection.

Unit Power Plant

The engine is a unit with the clutch and gearset, and is a four-cylinder, L-head block design with valves on the left. The cylinder dimensions are 3¾ by 4¼ in., giving a formula rating of 22.5 hp., and a piston displacement of 187.9 cu. in. Conventional practice is followed in the engine design. It is a three-bearing crankshaft type. The valves are com-

Driver's compartment and new metal instrument board on the 1917 Princess. All wiring is integral. Board is of dull black enamel with instructions of nickel set flush



Floating rear axle design used in the 1917 Princess, supplanting a semi-floating construction in the previous model. Housing is of pressed steel and a four-pinion differential is used with six-spline side gears

posite, having cast-iron heads and nickel steel stems, and have an opening in the clear of 1⅝ in. and a lift of 7/37 in. The outside diameter is 1 13/16. They are adjustable by removing the side plates and turning a nut on the end of the push rod.

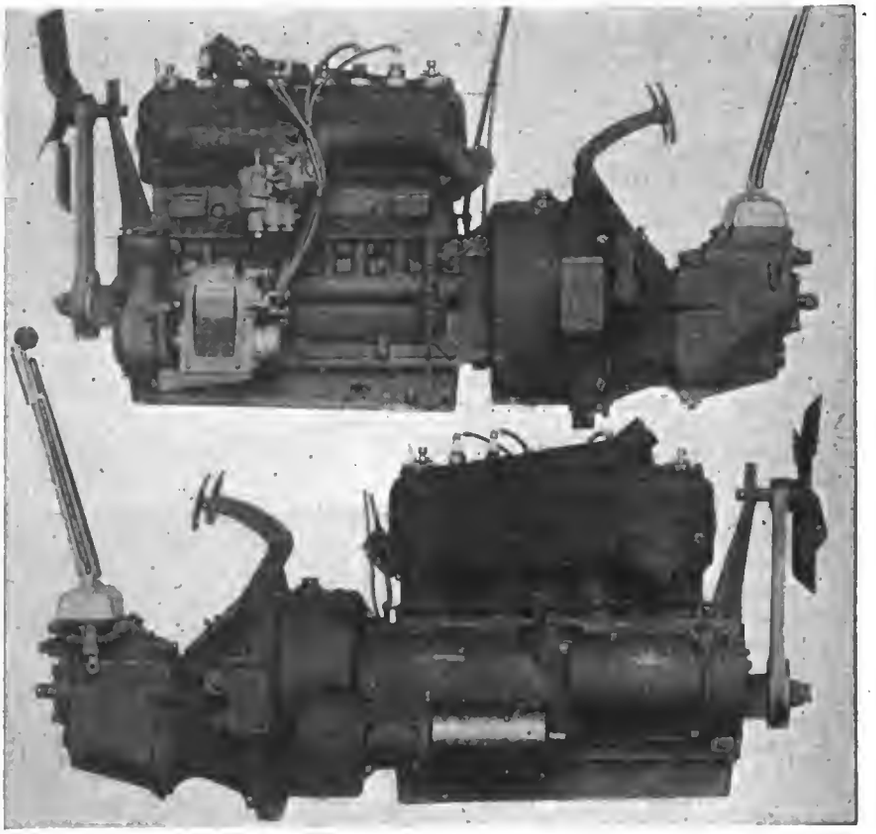
The silent chain drive for the timing gears and magneto runs in oil and has provision for adjustment. The lighting generator is also driven by silent chain.

Materials Standard

As far as materials are concerned, the engine is in line with usual practice, the connecting-rods being 0.30 to 0.36 carbon steel, drop forged and heat treated, the crankshafts are 0.35 to 0.40 carbon steel, and the cylinders and pistons of cast gray iron. The detachable cylinder head, is also of cast gray iron.

Oil is delivered by plunger pump driven from the No. 4 exhaust cam, to a dash sight feed and thence to the main bearings and thence to the splash troughs where the cylinders and other internal engine bearings are taken care of by the dip of the rods. The silent chain drive for the auxiliary devices is also cared for in this system by a separate lead which keeps the chain submerged in lubricant.

Ignition is by a Splitdorf Dixie type of magneto and carburetion by a Schebler.

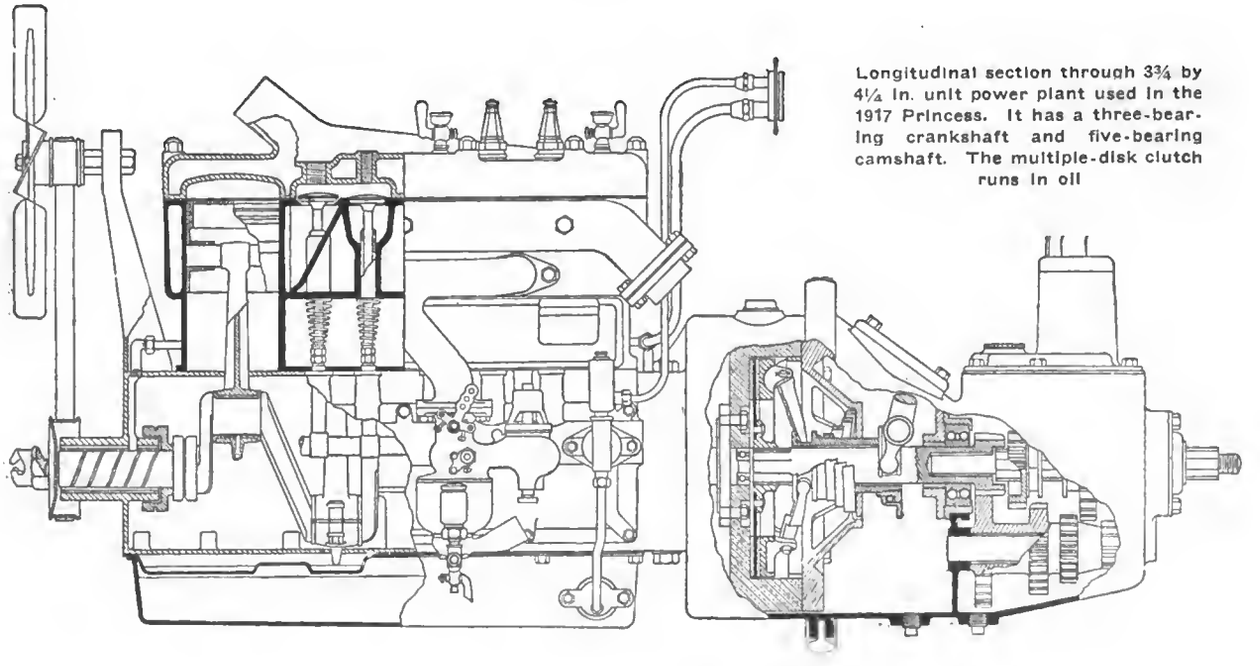


Both sides of the four-cylinder L-head unit power plant used in the 1917 Princess. The engine has a bore of 3¾ and a stroke of 4¼ in., giving a piston displacement of 187.9 cu. in. and a formula rating of 22.5 hp.

From the engine the drive is transmitted through a single steel dry-plate clutch to the Grant-Lees three-speed gearbox. The drive is the customary shaft with two universals. The rear axle is floating and the rear springs are three-quarter with the main leaf of vanadium steel. A guarantee against breakage of the main leaf is given for 2 years. The wheels are of hickory fitted in the rear with the 12-in. brake drums. The service brake is external contracting and emergency internal expanding on rear wheel drums, as shown in the view of the axle on page 860.

The new floating rear axle is amply strong, the housing being of pressed steel with a double lap on the differential housing; wall thickness is 5/32 in. A four-pinion differential is employed with six-spline side gears, gear ratio being 4 to 1, with twelve-tooth pinion and the gears are spirally cut. There is an independent adjustment on the bearings. Axle shafts are heat-treated chrome-nickel steel and 1¼ in. in diameter. Spokes are 1⅜ in. in diameter.

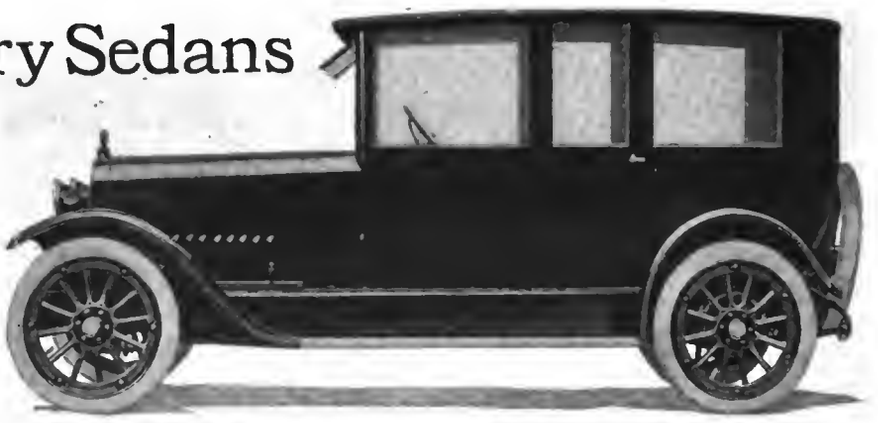
Fully equipped the car sells for $775, f.o.b. Detroit. The standard equipment includes electric starting and lighting, speedometer, Neverleak one-man top, two-piece, rain-vision windshield, two electric lights with dimmer, dash lamp, number bracket, robe rail, tire holder, extra rim, tool kit and electric horn.



Longitudinal section through 3¾ by 4¼ in. unit power plant used in the 1917 Princess. It has a three-bearing crankshaft and five-bearing camshaft. The multiple-disk clutch runs in oil

Two New Jeffery Sedans

Four and Six-Cylinder Types with Removable Tops for Summer Touring Brought Out By Nash Motors Co.



New seven-passenger sedan body mounted on Jeffery six-cylinder chassis and selling for $1,530. The extreme simplicity and severe lines are characteristic of the design. Note how closely the fenders follow the wheel contours

AS announced recently in the news columns of THE AUTOMOBILE, the Nash Motors Co., Kenosha, Wis., has brought out two new sedan models to meet the increasing demand for inclosed cars for Winter service. The new bodies, however, which are mounted on both the four- and the six-cylinder chassis, have removable tops which widen the scope of their usefulness throughout all seasons of the year. Both models have seating accommodations for seven passengers, the two folding seats being neatly concealed when not in use in the backs of the front seats, which are divided, as shown at the right.

The four-cylinder Jeffery chassis has a wheelbase of 116 in. and the block engine is 3¾ by 5¼. A three-speed-and-reverse gearset is used in connection with a disk clutch and semi-floating axle. The six has a 125 in. wheelbase and the engine is 3½ by 4⅝. Rear axle is semi-floating.

Interior of the new Jeffery sedan body, showing the divided front seats, wide door and dome light in the ceiling

Both bodies are two-door constructions, a feature which enabled the designers to provide unusually wide doors, while the aisle between the front seats, which makes this arrangement possible is of ample width to permit the passage of the occupants of the front seats to the rear and *vice versa* without inconvenience. Like the doors, the windows, which are of the French plate type, are of noticeably liberal dimensions, the rear window being 31 in. wide and 19½ in. in height. These windows drop 5 in. to give adequate ventilation in warm weather, providing a good circulation of air without permitting a draft on the heads of the passengers.

Upholstery is of gray whipcord and roll curtains on the windows, with numerous other touches of luxurious refinement aid the work of the Nash engineers in giving the new sedans all the comforts of a standard high-priced limousine. To insure entirely weatherproof qualities in the top, in all conditions of wind, rain, snow or sleet, a series of painstaking experiments were made. As a final touch, the large dome light in the center of the top was provided for light and warmth.

Knox Aviation Twelve Tested

(*Continued from page* 858)

diameter bored out to leave ½-in. wall. On this shaft is located the starting gear which through a train of gears connects with a starting motor by roller clutch.

Propeller Hub Mounting

The propeller end of the shaft is tapered to take the propeller hub which it drives through four heavy integral jaws. The propeller hub is drawn onto this shaft by right-hand nut and locked by a left-hand plug. The propeller hub with its inside flange is in one piece, incorporating the jaws to engage the corresponding jaws on the propeller shaft. The propeller hub is splined on the outboard end to take the splined flange, thus giving an allowable thickness of propeller of from 5 to 9 in. The propeller is clamped into place by eight bolts passing through both flanges. The propeller shaft, as well as the crankshaft at this end, is splined to take the propeller gears. Spline construction is very general throughout the motor.

Tachometer Driven from Camshaft

A tachometer is provided and driven from one end of the camshaft. It indicates propeller speed from 500 to 1500 r.p.m.

The horizontal driveshaft projects through the gearcase cover, so that the pulley may be added to drive a wireless generator if necessary.

At a test of this motor made at the Knox factory Saturday, Nov. 11, a run of 8 hr. was made. During the first 7 hr. the engine speed was from 1400 to 1600 r.p.m., pulling a load of 200 to 245 hp. For the last, or eighth, hour the speed was 1600 r.p.m., pulling a load of 300 hp. The average horsepower for the 8 hr. was 243, giving a total of 1948 hp. hr. with a gasoline consumption of 198.4 gal. This is 0.612 lb. per hp. hr., which could scarcely be taken as a fair test, as you cannot expect to get a true test with one-quarter and one-half throttle conditions.

No Air Blown on Plugs

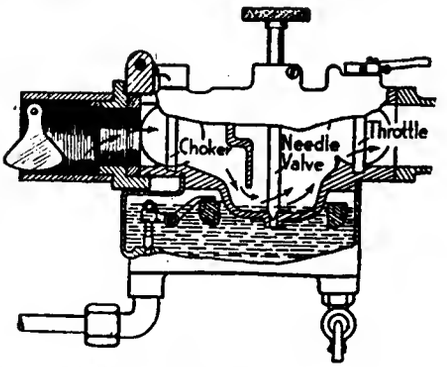
After the test had been under way for 40 min. a stop of 2 min. was made to change a spark plug, but after this no spark plugs were changed and no air of any kind blown upon the plugs. The water temperature was 108 deg. Fahr. at the entrance and 140 Fahr. at the discharge. Air temperature was 62 Fahr. at the start and 78 Fahr. at the finish, in the testing room.

The test was made with a Sprague electric dynamometer, as shown in the illustration at the top of page 856.

ACCESSORIES

Myle-Maker for Fords

THE Myle-Maker is an automatic auxiliary air adjustment for the standard Ford carbureter. A pendulum valve, actuated by the incoming air, hangs in a housing bolted to the air intake. It is secured by a set-screw, and may be fastened on by the owner in a very short time. When starting and at low speeds the valve restricts the air supply and causes a rich mixture to be sent to the engine; but at high speeds it is swung open, admitting more air. It is claimed that the device gives an easy starting mixture, as well as an economical mixture at normal speeds. Price, $5.—Myle-Maker Co., 323 East Twenty-third Street, Chicago.



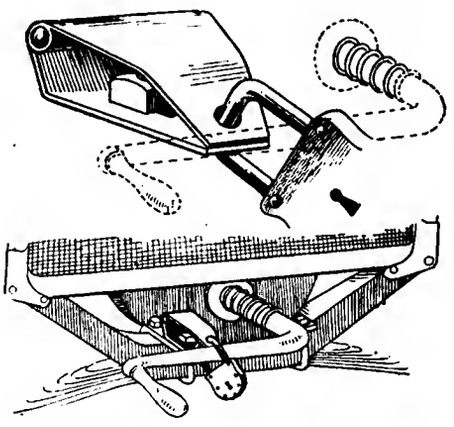
Myle-Maker air adjustment for Ford cars

Corning Conaphore

The Corning Conaphore is a device for preventing glare from headlights or spotlights. It is made either of yellow tinted glass, styled "Novoil," or of clear glass, having a smooth outer surface and a series of horizontal corrugations on the inner surface. These corrugations are said to bend the light rays down, until at no point are they more than 42 in. above the road. The yellow tinted glass is claimed to absorb the violet and blue rays, prevent glare, and transmit a ray that penetrates fog or dust. The sizes vary by ⅛ in. steps from 3 in. diameter to 11½ in. Price, Novoil, or yellow tinted glass, 3 to 4⅞ in., $1.30 per pair. Clear glass, 80 cents per pair. Other sizes in proportion.—E. A. Cassidy Co., 30 East Forty-second Street, New York.

Paramount Snubbers for Fords

These snubbers retard the upward motion of the body when recovering from a shock. One is installed on each end of the rear spring and consists of a resilient compression spring anchored in castings that are held in place by two cantilever springs. A strong webbing strap which buckles around the axle is fastened to the casting at the top of the compression spring. The lower casting is attached to the car spring by means of a tie-plate and two bolts. The installation only requires that the snubber be bolted to the rear spring, and the strap fastened around the axle, all of which may be done by the owner in a few minutes. Price, $6.—Detroit Engineering Products Co., Detroit, Mich.



Warner crank lock attached to Ford

Warner Lock for Fords

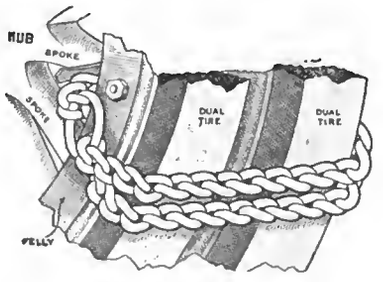
The crank of the Ford is locked in mesh with the crankshaft and the motor may not be turned over until the lock is released. A hinged metal member is bolted over the front spring clip and carries a heavy padlock that permits the crank to be held in mesh with the crankshaft. Price, $1.50.—G. H. Warner Co., 318 Century Building, Indianapolis, Ind.

Campbell Radiator Cover

The unlined covers are made of waterproof fleece-lined material with adjustable doors. The two-ply is imitation leather, waterproof, and the outside is lined with kersey blanket material quilted. Price, Ford unlined radiator cover, $1.38; Ford unlined engine cover, $1.14; Ford lined two-ply radiator cover, $1.58; Ford lined two-ply engine cover, $1.46. All other cars in proportion.—Perkins-Campbell Co., 622 Broadway, Cincinnati, Ohio.

Herman Truck Tire Chains

This device provides increased traction by means of three double cross-chains locked to each of the rear wheels. Each cross-chain is double, hence smaller than the equivalent single chain and said to reduce vibration. Price, per set of six double chains, 3 to 3½ in., $5; 4 to 4½ in., $6.50. Dual tires, 5 in., $13; 6 in., $15; 7 in., $17.—Herman Mfg. Co., 1420 Pennsylvania Avenue, Washington, D. C.

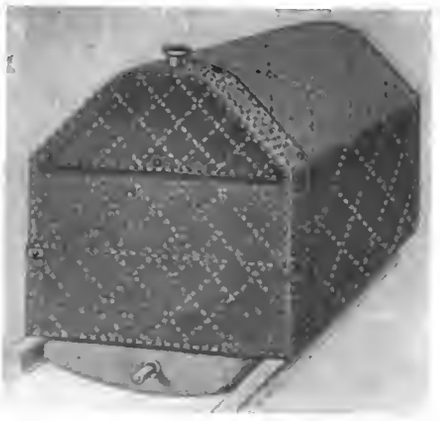


Herman tire chain for trucks

Allen Gloves

These are heavy, warm gloves for automobiling in winter. Over a detachable

Corning Conaphore glare preventer



Campbell radiator and hood cover

Paramount snubber for Ford cars

Genolite lighting system installed on a Ford engine

woolen glove is the leather glove proper, that may be worn separately if desired. These gloves are made in mitten, one-finger and glove shapes, finished either in black or tan leather. One of the many styles the company makes is illustrated herewith. They sell for $5 per pair.—Allen Glove Co., Gloversville, N. Y.

Stevens Valve Stem Reamer

By the use of the valve stem reamer guide and the special reamer, the worn valve guides of the Ford motor may be reamed 1/64 in. and fitted with the special valves having an oversized stem. The reamer guide is held in the valve seat by means of a clamp bolted in an adjacent cylinder-head bolt hole, holding the reamer in alignment and insuring an accurate job. The special valves supplied are of good quality, having the head electrically welded to the stem, which is 1/64 in. oversize. Price, valve stem reamer, $1.50; valve stem reamer guide, $1.50; oversize valves, 20 cents each.—Stevens & Co., 375 Broadway, New York.

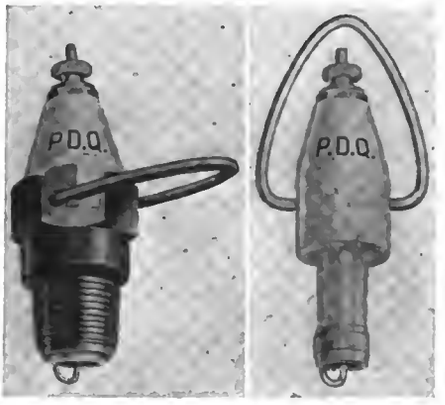
Amazon Tire

The Amazon is a reinforced non-skid tire, as shown in the illustration. Just below the outer edges of the tread heavy breaker strips are placed above the fabric body. It is claimed that these strips absorb the shocks and strains that otherwise would be transmitted direct to the tire carcass, and thus increase the life of the tire. Price, 30 by 3½, $14.75; 32 by 3½, $17; 34 by 4, $24.50, and 36 by 4½, $35.50.—Amazon Tire & Rubber Co., Akron, Ohio.

Genolite Lighting System

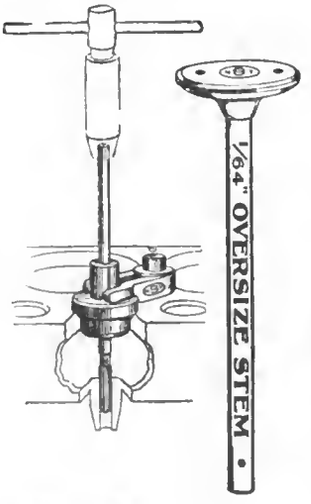
This lighting system for Ford cars includes a 2-volt generator, a single-cell storage battery, two side lights, a tail light and a switch, together with all brackets and wiring necessary to make the installation. The generator is mounted on a bracket secured by the two hose-coupling bolts to the forward end of the motor. The cut-out mounted on this bracket automatically connects and disconnects the generator and the battery at the varying engine speeds. The generator is driven by a spiral wire belt from a split pulley attached to the fan.

Genolite lighting system complete outfit



P. D. Q. spark plug which operates on the bayonet lock principle to simplify cleaning and priming

Allen gloves are made in several styles. This has a detachable inner glove



Stevens valve stem reamer for Fords

The wiring is of the grounded system, the wires being of various colors and properly labeled to eliminate wrong connections. The battery is of 40-amp.-hr. capacity and guaranteed for 15 months. The generator will generate from 8 to 10 watts, and is said to be more than ample to take care of the complete lamp load. No machine work is required in the installation, and it is claimed that the work may be done in 2 hr. Price, $19.85, f.o.b. Detroit.—Detroit Starter Co., Detroit, Mich.

P. D. Q. Spark Plug

The P. D. Q. is a two-pieced plug having a detachable porcelain. The union between the porcelain and the shell is made tight by accurately machining the joint, and is held by means of a bayonet catch. The construction is claimed to be durable, to permit easy inspection and cleaning, and to offer a ready means of priming. The plug is made either with the ½-in. standard S. A. E. or metric thread. Price, $1; extra porcelain, 75 cents.—Wolverine Spark Plug Co., Detroit.

Universal Master Wrench

A new principle is employed in this wrench, which may be used for turning square or hexagonal nuts, or for pipe. It has a non-adjustable V-shaped jaw, one side of which has fine, sharp teeth and the other is provided with a transverse V-block which slides on this member of the jaw. This block is so shaped that it will receive a square nut, a hexagonal nut or a pipe or rod and as soon as pressure is applied to the handle, will jam the work firmly against the other jaw. Quick adjustment is provided because it is only necessary to move the V-block along the jaw and there is nothing to hinder this motion.—Shepard-Prince Co., 18 East Forty-first St., New York City.

A section of the Amazon reinforced non-skid tire, showing strong inner structure

Industrial Miscellany

Factory

Goodyear Tire & Rubber Co., Akron, Ohio, has leased 10,000 acres of cotton land near Chandler, Tex., and has engaged E. W. Hudson, formerly government cotton expert, to take charge of the plantation. The company will engage in the raising of long staple Egyptian cotton for the manufacture of automobile tires, it is stated.

Shortage of skilled labor grows more acute each day, and the condition is general throughout Wisconsin. The motor car and truck industry is feeling the result. The Four Wheel Drive Auto Co., Clintonville, Wis., is advertising heavily in Milwaukee and Chicago newspapers for fifty turret and engine lathe, milling machine and drill press operators; ten bench hands; ten assemblers, and two inspectors, but has been able to get only a very small number of men. From 800 to 1200 skilled machinists would be given immediate employment if they were available.

At the present rate of rubber plant growth and activity in Akron it looks as if 15,000 more men would be needed in that city by March of the coming year.

The Firestone Tire & Rubber Co. is now employing 7000 men as against 3500 last year. This company now has four new buildings under construction, Goodyear has eleven, Goodrich five, and Miller two.

The Miller company used to employ 500 men. It now has 1750 on its payroll. The Goodrich factory, biggest of all, now has 14,000 employees and is unable to obtain the 2000 additional which are needed.

Production at the plant of the Westcott Motor Car Co., Springfield, Ohio, has increased about two and one-half times that of a year ago and a further increase is expected within the next half year. The present output is twenty-five cars a day.

Last July the factory was removed from Richmond, Ind., to its present location. The company was organized in Richmond in 1869 and became prominent as a manufacturer of horse-drawn vehicles. The increased demand for its automobile necessitated the removal to larger quarters, which are used entirely for the manufacture of the car.

The new plant consists of a three-story building, consisting of 176,000 sq. ft. of manufacturing space.

Macon Motor Car Sales Co., St. Louis, will be organized at once to sell The Macon, a car assembled at the factory of The All Steel Automobile Co., Macon, Mo. Salesrooms at 2206 Locust Street have been leased.

"Efficient Methods in Making Brake Lining Renewals" is the title of a folder recently issued by General Asbestos & Rubber Co., Charleston, S. C., manufacturer of the Garco brand of brake lining. This folder is written in plain, understandable style, and is designed to enable the inexperienced motorist to reline his brakes with perfect success.

Anger Engineering Co., 301-305 Sixteenth Street, Milwaukee, which manufactures the A. E. C. custom-built cars and operates a large service shop, has completed arrangements for the establishment of a large new plant at Twenty-sixth and State Streets, Milwaukee. The building will be of fireproof construction, 130 by 120 ft., one-story and basement, and contain the machine shop, factory, service shop and a public garage, together with offices and salesroom for the Ford agency recently acquired by the Anger company, and now conducted in separate quarters at 1517-1519 State Street.

Monarch Tractor Co., Chicago, has taken over the John Dornfeld Iron Works, Watertown, Wis., which in recent months have been devoted to the manufacture of farm tractors and sugar cane harvesting machinery. The Monarch company, a South Dakota corporation, is capitalized at $250,000 and now has more than $400,000 worth of orders booked. The tractor is styled the Never-Slip and is built in sizes from 6 to 50 hp. The 45-hp. type is used as the motive power of the Luce sugar cane harvester, an 11-ton machine which does the work of forty to sixty men on sugar plantations.

Maxwell Motor Co. at Kansas City, Mo., has already started work on the new assembling plant there, which will be ready for occupancy about the first of the year and which will cost $300,000. Bids are in for the erection of a large assembly plant at Windsor, Canada, where the Maxwell company plans to erect a building 100 by 300 ft., four stories high. It is planned to establish a chain of assembly plants throughout the country, and a site has already been secured at Minneapolis.

Personal

Charles Drum has been made the superintendent of production for the Springfield Body Co. Mr. Drum was formerly connected with the Haynes Mfg. Co.

The Springfield Body Co. will move to its new plant at Springwells, near Detroit, by Feb. 15 and will have a capacity of 100 bodies per day. At present the company has a capacity for thirty-five bodies daily.

Calvin Dunlap has become the vice-president of the International Commercial Corp. of New York. Mr. Dunlap was formerly the export manager for the Hupp Motor Car Co.

J. E. Turk, formerly connected with the Thomas B. Jeffery Co., Kenosha, Wis., has been appointed sales representative of the Chalmers Motor Corp. in Central West territory.

C. F. Barth has been appointed works manager for the C. F. Wilson Body Co. Mr. Barth was formerly the factory and production manager for the Murphy Chair Co.

A. E. Gluck, purchasing agent for the Packard Motor Car Co., New York City, has resigned. He has become president and general manager of the Abbott Motor Equipment Co., this city, distributor for the Warner lens, Block mirrorscopes, Amsco jacks and Twombly foot pumps. S. S. Frankenstyne remains as treasurer and sales manager. H. T. Stevenson succeeds Mr. Gluck as Packard purchasing agent, while W. C. Lyons takes up his work as head of the accessory department.

A. S. Gilchrist has been appointed manager of the Maxwell Motor Sales Corp., Baltimore, Md. He succeeds L. A. Tilley, who resigned. E. A. McKee, of the efficiency sales promotion department of the Maxwell company, has been attached to the local office indefinitely. Mr. Gilchrist is a former newspaper man, but has been with the Maxwell company for more than three years. He has been attached to the sales department and was also southwestern manager with headquarters at Houston, Tex.

J. R. Blocher, formerly branch manager of the Prest-O-Lite Co., in Baltimore has been appointed division manager and will make his headquarters here. E. W. Carpenter, who has been with the company for a long time becomes branch manager in Baltimore.

J. A. Muir, who was with the D. E. Truck Co. in Baltimore and for a number of years with the Mar-Del-Mobile Co., Packard and Saxon agents, has been appointed sales manager of the Monumental Motor Car Co., Kisselkar representative.

A. E. Hertzig, manager of the Baltimore branch of the Goodyear Tire & Rubber Co., Akron, O., has been appointed manager of the Washington branch of the company and will take care of the territory in both sections. L. J. Gemmil, who was manager of the Washington hranch will look after all of the government business exclusively.

E. T. Cole, manager of the Akron Tire & Rubber Co., Baltimore, Md., Ajax distributor, has taken the state agency for the Cleveland Standard Tire & Rubber Co. Charles E. Brooks will be in charge of the wholesale business throughout the state.

Harry Lowenstein has become manager of the R. M. Stein Co., Baltimore, Md. F. M. Sandy has become sales manager, and Charles Foutz, factory superintendent. The company operates two separate lines and handles the Moon and Ford.

A. E. Dixon has been made a member of the advertising department of the Chalmers Motor Co., Detroit. Before joining the staff of the Chalmers he was connected with the advertising departments of the Hupp Motor Car Corp. and the Packard Motor Car Co. Mr. Dixon will edit Chalmers Shop and Service, and will prepare pamphlets and other literature. The Chalmers Illustrated News has recently made its appearance.

A. H. Bailey has entered the Chemi Co., Richmond, Va., and has been elected vice-president.

M. A. Steele, late manager of the Henney Buggy and Stephens Motor branches of the Moline Plow Co., at Freeport, Ill., has been appointed general sales manager of the Stephens Motor branch with headquarters at Moline, Ill., H. J. Leonard, who has been assistant manager, succeeds Steele at Freeport.

F. C. Herschbach, of St. Louis, has resigned as assistant sales-manager for the Commercial Auto Body Co. of that city, for a similar position with the R. Haas Electric & Mfg. Co., Springfield, Ill.

G. O. Smalley has been elected first vice-president and general manager of the Bound Brook Oilless Bearing Co., Bound Brook, N. J. He succeeds the late Leigh Stanley Bache.

F. H. Whitman, formerly of Dodge Brothers, Detroit, has been appointed production engineer of the National Motor Vehicle Co., Indianapolis.

H. H. Brooks has been appointed superintendent of agencies at the Madison plant, Anderson, Ind. Brooks was one of the original incorporators of the Marathon Motor Works, Nashville, Tenn., where he served several years as sales and advertising manager. He was later connected with the Wayne Works, Richmond, Ind., and still later with R. A. Palmer in the Pontiac Chassis Co., Pontiac, Mich., in the same capacity.

Alvan T. Fuller, who handles the Packard line in Eastern New England from Portland, Me., to Providence, R. I., has been elected to Congress from Massachusetts. He entered the fight at the last minute as an independent against Congressman Ernest Roberts.

Dealer

Studebaker line has been dropped by the Corson-Berry Co., Springfield, Mass., and the Paige taken on its place. The Becker-Stutz Co., has taken on the Studebaker and moved to new salesrooms. W. F. Cassidy, who has the Grant Six, has moved into new quarters. The Western Massachusetts Longford Co. has shifted to 453 Worthington Street. The Harrington-Gifford Co. handling the Hudson Six, has also moved.

National Sales Co. has been organized at Providence, R. I., to handle the National line for Rhode Island.

Studebaker Corp., Worcester, Mass., has moved to temporary quarters on Main Street until its new building is finished.

Auto Trading Co., Pittsburgh, Pa., has taken over the Metz interests in that part of the State.

The Chevrolet Motor Co., of New York, has just opened a branch in Worcester, Mass.

The Springfield Body Co. has opened a branch at New York City in the Locomobile building, 16 West 61st Street, and has sent Charles Baasch on from the factory to take personal charge of it.

W. L. Patterson, St. Louis, has added Whitemore's automobile grease to the line handled by him at 3218 Locust Street.

Newsome Valve Co., St. Louis, has been organized to manufacture a tire tube invented by J. M. Newsome.

Auto-Devices Co., St. Louis, has taken the agency for the Hi-Comp piston ring. Salesrooms are at 3212-14 Locust Street.

Geller, Ward & Hasner Hardware Co., St. Louis, is territorial distributor of Prismolite lens.

Auto Sales Co., St. Louis, has removed into larger quarters at 908-10 Chestnut Street and becomes agent for the Wesco garage heating systems.

J. T. Conaghan has opened a garage and sales agency in Pekin, Ill., and will handle the Ford car, succeeding the Pinkerton Co., which retires from the Pekin field.

Bosch Magneto Co. has appointed the following new service stations: A. L. Ebbeson, Bangor, Me.; Auto Service Co., Bridgeport; Connel Wilson Electric Co., Jacksonville, Fla.; Harrington Motor Co., Mobile, Ala.; Garlock & Haynes, New London, Connel Auto Ignition Co., San Jose, Cal.; Essanell Electric Co., St. Paul; Tonopah Electric & Tire Co., Tonopah, Nev.; Tri-State Garage Co., Uniontown, Pa.; Tourist Garage & Motor Repair Co., Wilmington, Del.

Willys-Overland, Inc., selling organization has opened a direct branch at 33 Allyn Street Hartford, Conn., and succeeds in business The Overland-Hartford Co., at the corner of Allyn and High Streets. E. C. Bowman is manager of the new branch and associated with him is F. C. Brown, also a factory man. I. F. Maxson, manager of the Overland Hartford Co. will represent the Toledo factory in another capacity.

G. H. Grabb, Haynes and Auburn distributor, Hartford, Conn., has removed his salesroom to 289 High Street.

Keeney Truck Sales Co., 120 Allyn Street, Hartford, Conn., has taken over a portion of the Mattison building at the corner of Albany and Center Streets, and will use it as a service department for Selden and Vim commercial vehicles.

Adams-Bagnall Electric Co., Cleveland, Ohio, is now completing an addition to its factory with the installation of a complete vitreous or porcelain enameling plant.

Norton Monsarrat and Captain I. I. Morrison have organized the Stewart Motor Sales Co. for the purpose of handling Stewart trucks in central Ohio territory. They have opened sales room and a service station at 103 North Front Street, Columbus.

Three dollars a year

NO DULL-WINTER-SEASON FOR

Stewart Products

Stewart Products have a sale the whole year 'round—365 days in the year. A dull-Winter-business period is unknown to Stewart Products.

A Stewart Speedometer is just as necessary in winter as in summer.

A Stewart Warning Signal is absolutely indispensable for winter driving, when cars are enclosed.

The Stewart Vacuum System facilitates starting in cold weather—provides the only satisfactory gasoline feed.

A Stewart Tire Pump is certainly needed in the winter time.

Every engine needs a set of Stewart V-Ray Spark Plugs. A big, fat spark—intense and unfailing—is assured. Makes starting easier and insures smoother running of the motor.

Motoring is rapidly losing its seasonable aspect. No longer is the automobile for summer use only. This winter at least 75% of the automobiles will be in use most of the time. Comparatively few cars will be put up for the winter.

Can't you see the possibilities for a big winter business on Stewart products?

Vol. XXXV New York—Thursday, November 23, 1916—Chicago No. 21

G. M. C.—$2,250,000 Per Month

37,884 Cars Sold in 3 Months—Co. Does 17% of Car Export Business

G. M. C. FINANCIAL FEATURES

Monthly earnings	$2,250,000
Cash on hand	20,302,682
Drafts outstanding	2,643,445
Inventory	30,000 000
1917 plant expansions	2,055,000

NEW YORK, Nov. 22—General Motors Co. earnings are averaging $2,250,000 per month, according to President W. C. Durant, who also reported to the stockholders' annual meeting in Jersey City yesterday that cash and drafts on hand Nov. 15 amounted to $22,946,000, as compared with $11,311,000 on the same day last year. Mr. Durant stated that the company is doing 17 per cent of the entire export business in passenger cars, and that production for the 3 months ending Oct. 31 was 37,884 cars, a gain of 7612, as compared with the 30,272 manufactured in the same period of 1915.

The stockholders re-elected Mr. Durant president, and made Pierre S. du Pont chairman of the board. A. G. Bishop and C. S. Mott were elected vice-presidents. H. H. Rice is treasurer; T. S. Merrill, secretary; M. L. Prensky, comptroller; Standish Backus, general counsel; L. J. Kaufman, Charles H. Sabin and J. J. Raskob were elected members of the finance committee; and W. C. Durant, A. G. Bishop, C. S. Mott, Weston-Mott; W. E. Chrysler, Buick; W. C. Leland, Cadillac; F. W. Warner, Oakland; W. L. Day and R. H. Collins, General Motors Truck, are members of the executive committee.

Large blocks of material have been acquired by all the General Motors' subsidiaries to take advantage of low priced contracts to provide for increased output. The inventory is now about $30,000,000, or 25 per cent greater than required in normal times. A 20 per cent increase in output by all subsidiaries was predicted by Mr. Durant for the 1917 fiscal year of the company. Cadillac had dealers' orders for 24,000 cars, while at the present rate of production output will reach only 16,500 to 18,000 cars for this season.

Expenditures for improvements and extensions to the plants of the General Motors subsidiaries during the coming year will amount to $2,055,000.

The stockholders passed a resolution reducing the board of directors from seventeen to fifteen members. The retiring board was re-elected with the exception of A. H. Wiggin, president of the Chase National Bank, who declined re-election. One vacancy remained unfilled, so the board is now made up as follows: Pierre S. duPont, chairman; F. L. Belin, A. G. Bishop, W. P. Chrysler, R. H. Collins, W. L. Day, W. C. Durant, J. A. Haskell, L. G. Kaufman, W. C. Leland, J. H. McClement, C. S. Mott, J. J. Raskob, C. H. Sabin and F. W. Warner.

Chapin and Coffin Return from Mexican Border

DETROIT, MICH., Nov. 20—Roy D. Chapin, president of the Hudson Motor Car Co. and Howard E. Coffin, vice-president, have returned to Detroit from the Mexican border where they made a study of motor car conditions and of the use of the motor truck and the aeroplane.

Herman with Bour-Davis

DETROIT, MICH., Nov. 20—L. G. Herman has been appointed production and factory manager of the Bour-Davis Motor Car Co. Mr. Herman was formerly with the Rutenber Motor Co.

Alter Erecting Plant in Grand Haven

GRAND HAVEN, MICH., Nov. 22—The Alter Motor Car Co. is erecting a plant in this city consisting of four buildings which will be ready Dec. 15.

$20,000,000 Cord Tire Co.

Fabricord Tire Co. Absorbs Knight Tire Co.—To Add Other Units

CANTON, OHIO, Nov. 21—*Special Telegram*—As the first step in a merger of tire manufacturing concerns to represent a total capitalization of $20,000,000, the Knight Tire & Rubber Co., this city, has been absorbed by the Fabricord Tire Co., of which N. W. McLeod of St. Louis is president. The Fabricord Tire Co. is being formed for the purpose of welding together into one great organization several rubber manufacturing units and will devote particular attention to the production of cord tires under the McLeod patents. Capitalists of New York, Chicago and St. Louis are interested.

Cordin Leaves Packard

DETROIT, MICH., Nov. 20—A. E. Cordin has resigned from the Packard Motor Car to join the Pluyn-Ochs Co., importer into Russia of automobiles and accessories. Mr. Cordin, who has been Packard assistant sales manager for 6 years, will go to Petrograd to organize a branch for the Pluyn-Ochs company who plans a large expansion following the present war.

Packard Adjusts Organization

DETROIT, MICH., Nov. 20—H. H. Hills, sales manager of the Packard Motor Car Co., has been appointed to the position of assistant general manager. C. R. Norton, manager of truck sales, has been made the general sales manager. G. R. Bury, manager of carriage sales, has been promoted to the position of assistant general sales manager. These promotions are made to adjust the organization following the resignation of A. E. Cordin.

700,000 Ford Cars for 1917

Big Export Trade Planned—Factory in England—Dodge Suit Hearing Adjourned

DETROIT, Nov. 16.—The Ford Motor Co. plans to build 700,000 cars in 1917, entering automobile markets in every corner of the earth, and has investigators now seeking complete information in Russia, South America, France, England, other European countries, and the various English colonies. The company employs 50,000 men, is under a daily expense of $800,000, and is 150,000 cars in arrears. Ford stockholders have received $4,000,000 in dividends since July 31, when the fiscal year ended, and another large cash dividend is being contemplated for Jan. 1, 1917. On Nov. 9, stockholders were voted a 100 per cent dividend on the $2,000,000 capital stock. The company purchased material between July 31 and Nov. 11 amounting to $7,304,345.89, and had a bank balance in cash of $37,938,528.21 in various banks on Nov. 13, 1916. These and many other sums and plans of magnitude were revealed at the hearing of the suit instituted by Dodge Bros. against the Ford Motor Co. to restrain Mr. Ford from spending undivided profits in factory expansion. Other points determined by the hearing show Mr Ford's salary to be $150,000, and that of C. H. Wills, factory manager, to be $80,000 yearly.

Mr. Ford said that in addition to the Manchester plant in England, with a capacity for assembling 18,000 cars yearly, and the Canadian Ford plant with a capacity of 30,000 to 35,000 cars per year, the company will erect a plant in Southampton, England, with a capacity for the complete manufacture of 40,000 cars yearly. This, he said, is done to meet the plan of the allied nations to get together after the war and buy only in those countries favored by the allies.

Mr. Ford defended his policy of price reduction, and said the last reduction of the touring-car price to $360 was made to insure a 500,000 production, and that this mark was reached with a profit of about $6,000,000 to the company.

He admitted plans for the erection of blast furnaces at a cost of $11,000,000, and declared that he had samples of the iron made by the old cupola method and by the new method to be used in his plant, and that the difference was so great that its advantages could be easily observed by an inexperienced person. He estimated the saving effected by the new method to be between $10 and $15 per car, and thought it would take about 1 year to make up the expenditure of $11,000,000 for the new blast furnaces.

F. L. Klingensmith, vice-president of the Ford Motor Co., testified that the dividends for the year ending July 31, 1915, were $13,000,000, special, in addition to the regular 60 per cent dividend of $1,200,000. The next year the special was $5,000,000, in addition to the regular $1,200,000, or 60 per cent dividend. The company's cash balance on July 31, 1916, was approximately $52,000,000.

Owing to the refusal of W. L. Dunn, vice-president of the Highland State Bank to testify, the case has been adjourned until Friday.

Detroit's 1916 Output 960,000

DETROIT, MICH., Nov. 17—The value of automobiles produced in Detroit for 1916 amounts to $650,000,000 as compared with $330,000,000 in 1915. Automobile makers produced 960,000 cars during the present year, a gain of over 100 per cent, as compared with the 450,000 cars built in 1915. The report, given by the Bradstreet company, also shows that the automobile makers have erected four individual plants, each costing more than $100,000, and include the structures built by Chalmers, Packard and Continental Motors.

Woodard President of Gillette Tire

EAU CLAIRE, WIS., Nov. 18—S. P. Woodard has become president of the Gillette Safety Tire Co., this city, maker of the Gillette tire. Mr. Woodard recently resigned as general sales manager of the New Jersey Car Spring & Rubber Co., Jersey City, N. J. His office as president of the Gillette company will be in New York.

Myers with General Engineering Co.

DETROIT, MICH., Nov. 17—T. P. Myers has joined the staff of the General Engineering Co. and will have charge of the Doble steam power plant development in the truck field. Mr. Myers was formerly manager of the truck division of the Packard Motor Car Co. in New York.

Pettit J. I. Case Vice-President

RACINE, WIS., Nov. 21—F. R. Pettit, has been appointed vice-president of the J. I. Case Plow Works, Racine, to take effect Jan. 1. He is now general purchasing agent of the J. I. Case T. M. Co.

Hastings Holley Chief Engineer

DETROIT, MICH., Nov. 16—D. T. Hastings has become chief engineer of the Holley Brothers Co., maker of the Holley carbureter.

Gloetzner Covert Chief Engineer

DETROIT, MICH., Nov. 22—A. A. Gloetzner, has become chief engineer and manager of sales of the Covert Gear Co. He was formerly chief engineer of the Bour Davis Co.

Velie Companies Merge

More Efficient and Economical Operation—Capital Increased to $2,000,000

MOLINE, ILL., Nov. 20—The Velie Motors Corp. has been formed as a result of the merger of the Velie Motor Vehicle Co., maker of the Velie automobile and the Velie Engineering Co., maker of the Velie truck. The merger does not affect the Velie Carriage Co. which will continue to be operated as a separate institution manufacturing a full line of horse-drawn vehicles.

The capital stock of the Velie Motors Corp. has been increased to $2,000,000, accomplished without the introduction of new capital. Velie stock is not available on the open market.

The personnel of the directorate remains unchanged.

Gaulois Tire Changed to Bergougnan—To Manufacture in United States

NEW YORK CITY, Nov. 21—The Etablissements Bergougnan of Clermont-Ferrand, France, maker of the Gaulois tire, has changed the name of its product to Bergougnan, in both solid and pneumatic types, and will build tires in this country.

The works of the company in France have been taken over almost entirely by the French War Department and the working force is kept busy day and night turning out solid tires for the quartermasters of the army for use on the ammunition and other trucks.

This has seriously interfered with the shipment of tires to this country until now the company proposes to manfacture all of its straight side tires here.

Although this is announced as a temporary measure imposed by the necessities of the war, it is not at all unlikely that it may result in the establishing of a Bergougnan factory in this country.

The American made tire will be offered to the public Dec. 1.

Take Up Woodard's Sales Duties

JERSEY CITY, N. J., Nov. 20—J. W. Paul and L. K. Rittenhouse will have charge of the sales of the mechanical goods and tire department, respectively, of the New Jersey Car Spring & Rubber Co., this city, thus taking up the duties vacated by the recent retirement of S. P. Woodard as general sales manager. Mr. Paul has been assistant sales manager of the company, and was formerly manager of the Diamond Rubber Co.'s Pittsburgh branch. Mr. Rittenhouse comes from the Norwalk Tire & Rubber Co.

Standard Parts Co. Formed

Perfection Spring and Standard Welding Consolidated in $35,000,000 Merger

CLEVELAND, OHIO, Nov. 22—*Special Telegram*—The Standard Parts Co. of Cleveland has been formed by the consolidation of the Perfection Spring Co. and the Standard Welding Co. of this city. The new company is capitalized at $35,000,000, consisting of $10,000,000 in 7 per cent cumulative preferred stock, of which half is issued now, and $25,000,000 common stock, of which $8,000,000 is issued now. Borton & Borton are offering $4,000,000 preferred to the public at par. The common stock to be issued has been underwritten by a syndicate and will not be publicly offered.

Officers for the new company have not yet been determined, but the board of directors includes J. H. P. McIntosh, Sr., F. F. Prentiss, H. P. McIntosh, Jr., T. E. Borton, Christian Girl and E. W. Farr, all of Cleveland, and A. H. Goss of New York.

The consolidation eliminates friction regarding the Perlman Rim patents as the Standard Parts Co. has contracts with the Perlman interests, permitting manufacture of demountable rims at a fair profit.

Holders of Perfection Spring preferred stock will receive Standard Parts Co. stock share for share. With Perfection preferred figured at $110 a share, they may, if they desire, take one share of Standard Parts preferred plus $10 cash or $110 a share cash for each share of Perfection preferred. Holders of Perfection common are offered two shares of Standard Parts common for one of Perfection. As Standard Parts common is underwritten at $85 a share, this is equivalent to $170 a share for Perfection.

Holders of Standard Welding stock receive $250 a share cash with the privilege of joining the syndicate underwriting Standard Parts common to the extent that they may underwrite half as many shares of Standard Parts common as they owned of Standard Welding.

The consolidation will constitute the largest maker of automobile springs in the world and one of the largest producers of automobile rims, bands and facings for solid tires, bicycle and motorcycle formed parts and light gage steel tubing. Both companies have a vast amount of business on hand and are covered for the future on raw material.

Sun to Market Single Chassis

ELKHART, IND., Nov. 20—The Sun Motor Car Co. will market a single chassis for 1917 and this will carry five-passenger touring, seven-passenger touring, four-passenger roadster and five-passenger sedan bodies, the prices remaining $1,095 to $1,295. The standard finish of all bodies is royal blue with cream wheels, and equipment includes the newest type of slanting windshield. The car is powered with a 3⅛ by 5 detachable-head, block-cast motor, and power is transmitted through Borg & Beck plate clutch to a three-speed gearset; the axle is floating. Other specifications include Remy starting, lighting and ignition, Rayfield carbureter, Stewart vacuum fuel system, and Jacox steering gear. The wheelbase is 116 in. and the tires are 34 by 4, non-skid in rear.

Moyer Resigns from Champion Ignition

DETROIT, MICH., Nov. 17—Arthur W. Moyer has resigned his position with the Champion Ignition Co., where he handled the factory business. Mr. Moyer was formerly with A. R. Mosler & Co. He will return to his original business, the Moyer-Shaw Mfg. Co.

Merrill Purchasing Agent for Hood

DETROIT, MICH., Nov. 16—Instead of R. B. Newell, as announced last week, it was R. B. Merrill who was appointed as purchasing agent for the Wallace C. Hood Service Bureau. Mr. Merrill was formerly connected with the Packard Motor Car Co.

Macey Harroun Sales Manager

DETROIT, MICH., Nov. 20—J. W. Macey has been appointed sales manager of the Harroun Motors Corp. Mr. Macey was formerly connected with the Ford Motor Co.

Taylor with White Star Refining

DETROIT, MICH., Nov. 20—Kirk Taylor has been appointed sales manager for the White Star Refining Co. Mr. Taylor was formerly with the Evapco Mfg. Co.

Collins to Join Parker Rust Proof

DETROIT, MICH., Nov. 17—B. W. Collins, formerly assistant to Walter Fry, president of the Springfield Body Co. has joined the staff of the Parker Rust Proof Co.

Cornelius with Parker Rust Proof

DETROIT, MICH., Nov. 20—W. M. Cornelius has been appointed as assistant to the president of the Parker Rust Proof Co. Mr. Cornelius was formerly the secretary of the Security Commission at Lansing.

Selden Truck Co. Advances Dupuy

ATLANTA, GA., Nov. 21—C. L. DuPuy, who for the past 5 years has been representing Selden trucks in the local territory, will, on Dec. 1, become southern division sales manager of the Selden Truck Co., Rochester, N. Y.

Five Cos. Raise Car Prices

Packard, Kissel, Marmon, Empire and Paige Feel High Production Costs

DETROIT, MICH., Nov. 20—Packard Motor Car Co. has increased the price of the model 225, the smaller Twin-Six, $185, and the larger Twin-Six, model 235, $235, making the new prices, $3,050, and $3,500 respectively on all open cars. This applies to all deliveries after Feb. 1 and before that date to any cars built after 4500 of the new models have been produced. Increased cost of manufacture is the reason for the raise.

Kissel Price Advance Determined

HARTFORD, WIS., Nov. 21—The Kissel Motor Car Co. will increase the prices of the Hundred Point Six models on Dec. 1, 1916. The five-passenger touring and three-passenger roadster, not built for the All-Year top will be $1,195, an increase of $100. The four- and five-passenger Gibraltar models, built for the All-Year top will advance from $1,195 to $1,285; the five-passenger Victoria, with the detachable town car top will be $1,950, an increase of $100; the five-passenger All-Year Sedan and the four-passenger All-Year Coupé, both including the summer tops will advance from $1,520 to $1,635. Wire wheels will be supplied for $100 extra.

Marmon Prices Will Advance $150

INDIANAPOLIS, IND., Nov. 20—Nordyke & Marmon Co., will advance its prices $150 on Jan. 1, 1917. The new prices will affect cars purchased from this date for delivery after the first day of the coming year. Cars ordered, however, for delivery before Jan. 1, will be sold at the old prices. The Marmon touring car is now selling at $2,950.

Empire to Advance Prices

INDIANAPOLIS, IND., Nov. 20—The Empire Automobile Co. will advance prices on all its models soon after Dec. 20. Dealers are guaranteed present prices only until that date. The advance probably will be between $70 and $100.

Paige to Increase Prices

DETROIT, MICH., Nov. 20—The Paige-Detroit Motor Car Co. will increase the prices of its cars on Jan. 1, 1917.

Doak Joins Ohio Electric

TOLEDO, Nov. 22—R. R. Doak has become assistant sales manager of the Ohio Electric Car Co., this city. Mr. Doak was formerly manager of the St. Louis branch of the Woods Motor Vehicle Co., Chicago.

Akron—The Miracle Tire City

$203,100,000 Worth of Rubber Products Manufactured—54,000 Tires a Day

AKRON, OHIO, Nov. 17—More than 11,522,650 tires will mark the total production from Akron for 1916. Business for the year will amount to $203,100,000 gaged by the output of the past 11 months, an increase of 65 per cent over the preceding year. Some idea of the vast and stupendous industry may be had from the fact that 158,315 freight cars are necessary to carry the year's production to the various destinations. The City, which in 1910 had a population of only 69,000, now has 51,150 people employed in rubber manufacture. Floorspace covering 88 acres and machinery costing more than $2,500,000 have been added in 1916 and 12,005,000 sq. ft. of floorspace is now devoted to the rubber industry. Present capacity as increased by recent additions allows a daily total output of 54,000 tires.—19,837,750 for 12 months. This is approximately equal to existing demand and it is a safe prediction to state that Akron will manufacture more than 20,000,000 tires in 1917.

Every factory is operating to full capacity, erecting still more buildings, planning on a greater increase of machinery, and bending every effort to meet the constantly growing demands. Goodrich has added 21 acres of floorspace and hundreds of intricate and expensive machines to its plant, and at present is erecting new structures as quickly as men and materials can be secured. The company has a total floorspace exceeding 100 acres. The numerous buildings stretch over many of Akron's streets and are connected by a tunnel system more than 5 miles long. Over 20,000 men are employed, who work in three 8 hr. shifts. Business for this year, judged by a report of the first 8 months, will total $77,000,000 as compared with $55,416,000 in 1915. The daily capacity at the Goodrich plant is 20,000 tires.

Goodyear announces a total business of $63,000,000 for this year as against $37,000,000 in 1915, an increase of 85 per cent. The company employs 15,000 men, occupies 75 acres of floorspace and has a daily capacity of 17,000 tires. Factory additions totaling more than 30 acres have been made in the past year. The company manufactured 2,000,000 tires in 1915, approximately 3,500,000 for 1916, and plans to produce 6,000,000 next year.

Firestone has increased the number of men employed from 3900 in 1915 to 8000 in 1916, an excellent gage to the growth of the institution. Factory additions total 11 acres for the past year and give the company 37 acres of floorspace. The company handles approximately sixty-five freight cars daily for shipment of its products. The factories are unique in construction, manufactured with brick, steel and glass, and consisting of four sections, each 700 ft. long and five stories high, but practically under one roof. Business for 1916 amounts to $33,250,000 as compared with $25,000,000 in 1915. Machinery and other equipment costing $1,500,000 has been added and has increased the daily capacity to 12,500 tires.

Miller, General and Kelly-Springfield, have each enjoyed a remarkable growth. Additions of 24 acres of floorspace have been added to the Miller plant and the capacity has been increased from 1000 to 3000 tires per day. The company manufactured 125,000 tires in 1915, 300,000 in 1916, and plans to produce 500,000 next year.

Swinehart occupies 80,000 sq. ft. of floorspace and increased their business from $1,250,000 in 1915 to $1,500,000 in 1916. It employs 400 men and has a daily capacity for about 500 tires.

General has added 35,000 sq. ft. of floorspace and more than doubled its business in the past year.

An eight-story building is in process of erection on the Miller company's grounds to replace several old structures. When this is completed the concern will have approximately four times as much floor space as they occupied 10 months ago.

—

Gillette Tire Installing Machinery

EAU CLAIRE, WIS., Nov. 18—The first shipments of machinery and other equipment for the new plant of the Gillette Safety Tire Co., Eau Claire, Wis., have arrived and are now being installed. It is possible that first operations will be possible shortly after Dec. 1, with the entire works operating by Jan. 1.

—

Bukolt Tire Protector in New Plant

STEVENS POINT, WIS., Nov. 18—The Bukolt Tire Protector Co., Stevens Point, Wis., is taking occupancy of its new factory. The output of steel tire protectors will be increased from 50 pairs a day to 300 pairs. The tire protector business will be incorporated as soon as possible and will have a capitalization of about $200,000.

—

Auto Body Co. Increases Floor Space

LANSING, MICH., Nov. 17—The Auto Body Co. is erecting ten additional dry kilns which will make a total floor space of 10 acres occupied by the company for the manufacture of their products. The kilns will cover ground 99 by 165 ft. which the company recently purchased.

Briscoe Plant on West Coast

Will Cost $500,000—Mr. Briscoe on Coast to Determine Station

DETROIT, MICH., Nov. 17—The Briscoe Motor Corp., Jackson, Mich., will erect an assembly plant at a cost of approximately $500,000 at one of the larger cities on the Pacific Coast. Benjamin Briscoe, president and L. E. Wilson, vice-president, of the corporation will leave for California in the next few days and will determine the location. The Briscoe factory is reaching out after business on the western coast of South America, as well as Australia, New Zealand, Japan and Russia, and plans to have a plant with a capacity for assembling 20,000 cars a year.

The company has recently completed the factory at Jackson and at the present time occupies 48 acres of floor space in ten separate buildings.

—

Dann Products Opens Cleveland Plant

CLEVELAND, OHIO, Nov. 20—The Dann Products Co., maker of Dann spring lubricating inserts, has opened its new plant here. The building is of modern brick and steel construction with ample lighting and ventilation provisions. In spite of the 30,000 sq. ft. of floorspace which the new plant contains, the company is already planning to enlarge it and additional land has been secured for this purpose.

—

Fire Damages Saxon Plant

DETROIT, MICH., Nov. 20—Fire at the plant of the Saxon Motor Car Corp., to-day, damaged a structure used for truck production, and a part of the building used for offices, to an extent estimated at $60,000. The loss is covered by insurance and will in no way hinder the productive facilities of the concern. In fact, production was in process within 1 hr. after the fire had been overcome. The fire was started by an employee who held a lantern while he poured gasoline into the truck tanks.

Anderson Electric Expands Cleveland Plant

DETROIT, MICH., Nov. 17—W. C. Anderson, president; William Lock, treasurer, and Wilson Critzer, auditor of the Anderson Electric Car Co., are in Cleveland, arranging final details for extensions to the company's Cleveland plant, where motors and other parts of Detroit Electric cars are manufactured.

Carl Fisher in Tractor Co.

To Build One-Wheel Machine in Indianapolis—New Factory Being Built

INDIANAPOLIS, Nov. 20—Carl G. Fisher, president of the Prest-O-Lite Co. and also the motor speedway here, has taken another step in the automobile trade following closely upon the announcement of the vacuum brake by his concern a few weeks ago. The latest Fisher activity is in the farm tractor field. For some time it has been known that Mr. Fisher has been in Detroit examining a one-wheel tractor design developed there some months ago. Plans have progressed rapidly for the manufacture of this tractor and to-day a factory is being built here for its manufacture. Concrete for the factory is being poured and the building will be complete in 90 days.

The organization of the company is not entirely completed as yet, but C. B. McCutcheon, president of the Ross Automobile Co., Detroit, will be president. The other officials are not yet known. The services of one of the best known men in the trade has been secured as factory manager.

The one-wheel tractor to be built has been examined by many in the industry during the last year and has been very favorably considered. It has given convincing demonstrations of its ability to work on all kinds of soil.

Ford Tractor Co. Formed in Del.

DETROIT, MICH., Nov. 17—The Ford Tractor Co. has been incorporated under the laws of Delaware to manufacture tractors and other machinery. The capital stock is $1,000,000. Incorporators are W. Baer Ewing and C. M. Hertig, of Minneapolis, and F. D. Buck, of Wilmington, Del.

Lane Here from Australia

NEW YORK CITY, Nov. 22—R. T. Lane, representing the Chevrolet in Melbourne, has arrived in this city. Mr. Lane states that since the outbreak of the war there has been an increasing demand in the Antipodes for goods of American manufacture. Business conditions are prospering in Australia.

Compensating Driving Axle on Market

PHILADELPHIA, PA., Nov. 16—A new device to prevent skidding called a compensating driving axle to take the place of the differential will be put on the automobile market by the A. C. Axle Mfg. Co., this city, formed this year with a capital of $1,000,000 to manufacture this invention for use on old and new cars. This new driving mechanism is equipped with ratchet clutches in the axle, instead of the gear wheel system of the differential. A feature is a positive drive on both wheels. In turning a corner the wheel on the short curve drives the car, the wheel on the long curve compensates the difference.

J. D. Allen, the inventor, has estimated the cost of equipping a car with this invention at $175.

The officers of the company are: J. D. Allen, president; A. P. Fisk, vice-president; A. C. Bunnell, secretary; and H. W. Savage, treasurer.

Cocorda and Giaugue, Peugeot Engineers, Here Visiting Factories

NEW YORK, Nov. 18—Two Peugeot engineers are at present in this country visiting several of the automobile factories. They are Messrs. Guido Cocorda, chief engineer, and Albert Giaugue, chief of the service department of the Peugeot factory in Paris. They expect to be in this country until Dec. 15. At present the Peugeot company is engaged in the manufacture of aviation engines, motor trucks, and munitions. The factory has been more than doubled since the start of the war. The manufacture of passenger cars has practically ceased, but in the near future will be taken up.

Sterns Tire & Tube Co. of Canada Formed

DETROIT, MICH., Nov. 17—The Sterns Tire & Tube Co. of Canada, Ltd., has been formed with an authorized capital of $1,000,000. It will locate at Windsor with a one-story factory, 100 by 150 ft.

Officers of the company include N. J. Morrissey, Pickering, Ont., president; Edward Sterns, St. Louis, Mo., director and consulting engineer; C. J. Gibson and A. S. Chapin, Toronto, directors; E. M. Carruthers, Toronto, secretary and treasurer.

Pirelli Sails for Italy

NEW YORK CITY, Nov. 20—G. A. Pirelli, son of the owner of the Pirelli Tire Co., Bicocca, Italy, who visited this country and South America this year, has sailed for Italy. Mr. Pirelli visited the two countries on account of a possible large sale of the Pirelli tires. While in this country Mr. Pirelli made extensive purchases of machinery for the enlargement of his plants in Bicocca, Italy, Barcelona, Spain and Southampton, England.

Assmus Goes to Cuba for Maxwell

DETROIT, MICH., Nov. 17—C. O. Assmus, in charge of sales promotion of the export department of the Maxwell Motor Co., left Detroit for Cuba, Nov. 16, where he will be stationed for a month.

Ford Cars To Use Kerosene

Holley Kerosene Carbureter On Sale in Ford Sizes in U. S. Feb. 1

NEW YORK, Nov. 18—The use of kerosene as an automobile fuel will probably be considerably forwarded by the fact that the Holley company contemplates selling kerosene carbureters for Ford equipment in this country and England. Beginning with Jan. 1 delivery in England the Holley kerosene carbureter will be sold for equipment on Ford cars; and beginning with Feb. 1 it will be for Ford equipment in the U. S. A.

Duplex Truck Co. Formed—$1,000,000 Capital

DETROIT, MICH., Nov. 20—The Duplex Truck Co., capitalized at $1,000,000, has been organized to take over the Duplex Power Car Co., Charlotte. The new company will move the business to Lansing where a site will be purchased and a factory erected.

This company was the first to build an internal gear-driven four-wheel-drive truck. The Jeffery Quad is built under its license.

Under the new organization H. M. Lee, assistant sales manager of the Reo company, is president and general manager; H. E. Bradner, vice-president; G. W. Hewitt, credit manager of the Reo company, is secretary and treasurer; Harry Harper and Elgin Miflin, directors of the new company. The officers of the old company were F. P. Town, president; Fred Murray, secretary; H. H. Bryan, treasurer, and F. L. King, vice-president.

L-M-H Development Co. to Make Tractors

DETROIT, MICH., Nov. 16—The L-M-H Development Co. has been formed as a holding company capitalized at $30,000 for the development and construction of a tractor, an invention of H. M. Leonard. Incorporators are John Hurlburt, Detroit; H. M. Leonard, who has been chief engineer of the Duplex Power Car Co., Charlotte, Mich., and Clarence Martin, Jackson, Mich. It is later planned to organize a larger company. Mr. Leonard claims that his new tractor will run equally well in either direction and has four speeds forward and also in reverse, that it will turn in a circle the radius of which is its wheelbase, and that it will pull three plows. It is a four-wheel drive, weighs 3300 lb. and will sell for $800. The larger company will probably be organized in July, 1917.

Peugeots Win Road Classics

Resta Captures Championship—Wins Vanderbilt—Aitken Wins Grand Prize

GRAND PRIZE WINNERS

Car	Driver	M.P.H.	Prize

CHAMPIONSHIP AWARDS

	One	Two	Three	Trophy
A. A. A.	$7,000	$4,000	$2,500	Cup
Boech	2,000	1,000	500	Cup
Goodrich	5,000	3,000	2,000	
Total	$14,000	$8,000	$5,000	

SANTA MONICA, Nov. 22—The two road racing classics, the Vanderbilt, won by Resta, and the Grand Prize, won by Aitken, practically closed the American racing season last Thursday and Saturday on the Santa Monica course. The two events brought forth new records and as keen a competition as has been seen this year. As both races were included in the American Automobile Assn. championship standing with but 660 points difference between the two leaders, Resta and Aitken, it was naturally expected that America's two premier road races would result in a sharp battle for the coveted position as the premier racing driver of the United States, and the championship award of $14,000 given by the A. A. A. and the Bosch and Goodrich companies. Resta had $6,000 difference between first and second position awards, the last race, the Grand Prize, brought out not only keen competition between Resta and Aitken, but also established a precedent in American racing events. As Resta had won the Vanderbilt and had 4100 points much depended on the winning of the Grand Prize by Aitken to overcome his lead in points. Aitken had 3440 points.

As Aitken had dropped out in the first lap on account of a broken piston, his chances for the coveted points were nil. It was, however, thought that if he could take Wilcox's place in his Peugeot and thereby win the race, he would be entitled to a proportionate number of championship points. As a result, quite a little controversy developed when he did win and the precedent was sustained by the A. A. A.

Resta Now Champion

Resta is now the undisputed claimant of the championship title, as Aitken, it is stated, will not race at the Ascot Speedway on Thanksgiving Day, the last championship event. Incidentally, Resta first definitely established his standing as a racing driver in this country at last year's Vanderbilt and Grand Prize by winning both events, a feat never before paralleled. This year he was on his way to repeating the former performance but was put out in the eighteenth lap.

This year the race was run only by the American Automobile Assn. and not under the joint jurisdiction with the Automobile Club of America, which controlled the Grand Prize.

1916 Speedway Champion

Dario Resta

Wilcox-Aitken Car Winner

Aitken Relieves Team-mate in Grand Prize—Receives No Points

SANTA MONICA, CAL., Nov. 18—*Special Telegram*—A Peugeot, driven by Wilcox and Aitken, won the 403.249-mile Grand Prize road race to-day over the 8.04-mile oblong Santa Monica course, establishing a new record for that classic of 4 hr., 42 min. and 47 sec., or 85.59 m.p.h., as against 7 hr., 7 min. and 57 sec., or 57.50 m.p.h. in the 1915 race at San Francisco, made by Resta in a Peugeot. Cooper in a Stutz finished second, averaging 83.74 m.p.h. To-day's race not only established new records but it also established a precedent in the awarding of points in the championship events. Wilcox, who drove the winning car for the first twenty laps, receives 416 points, or 20.8 points for each lap. Aitken, who relieved Wilcox and drove the remaining 28 laps, according to the A. A. A. decision, receives no points. As a result, Resta retains his lead in the championship race and may be called the leading driver of 1916. The precedent established before this race was that set by Rickenbacher this year at Indianapolis when he was refused points after having taken Henderson's Maxwell as relief driver and finishing within the money. Included in the records to-day is that of a new world's non-stop road race record made by Patterson in a Hudson Supersix which finished third, averaging 78.13 m.p.h. Roads, also driving a Hudson, finished fourth, which is the same position he held in the Vanderbilt last Thursday.

Much depended upon to-day's race if Aitken was to overcome Resta's lead in

ELIMINATIONS IN GRAND PRIZE RACE

Car	Driver	Lap	Reason
Peugeot	Aitken	1	Broken pieton
Herculee	Agraz	2	Broken rod
Kissel	Anderson	5	Broken valve
Duesenberg	Moosie	6	Broken clutch
Owl Special	Carlton	6	Broken pump ehaft
Mercer	Pullen	8	Burned up
Hudson	Vail	9	Burned bearing
Omar	Toft	10	Burned clutch
Gandy	Price	10	Broken clutch
Marmon	Jackson	13	Wreck
Durant Special	Durant	17	Broken valve
Cody Special	Cody	33	Motor trouble
Peugeot	Reeta	18	Motor trouble
Duesenberg	Rickenbacher	26	Broken drive shaft
Dueeenberg	Buzane	27	Broken piston
Mercer	Ruckstell	39	Broken pressure line

ELIMINATIONS IN THE VANDERBILT CUP RACE

Car	Driver	Lap	Reason Assigned
Gandy Special	Price	4	Burned clutch
Cody Special	Cody	5	Axle trouble
Duesenberg	Rickenbacher	6	Sheared high gear
Owl Special	Carleton	6	No tires
Mercer	Ruckstell	8	Ignition
Omar	Toft	9	Connecting rod
Marmon	Jackson	10	Motor trouble
Duesenberg	Moosie	11	Sticking valves
Mercer	Thomas	12	Radiation
Duesenberg	Buzane	15	Cracked cylinder
Peugeot	Aitken	19	Broken intake valve
Mercer	Pullen	31	Motor trouble
Chowchilla	Bolden	21	Broken crank ehaft

points in the American Automobile Assn. championship race, and as a result every possible means to win the coveted points and $14,000 in prize money was resorted to. Consequently when Aitken, who was in second place, just 660 points behind Resta in the championship column, dropped out, after the first lap with a broken piston, his chances for winning the race looked slim.

However, when Wilcox was signalled to stop in the fifth lap, it was soon apparent that Aitken would attempt to win the race in Wilcox's car. Wilcox stopped in the ninth lap, stating that he was tired and asked to be excused, but was refused permission. He was in second position at the time of his stopping when he lost 2 min. On the fifteenth lap he took the lead, his average at that time being 87 m.p.h.

Resta to the Pits

On the sixteenth lap Resta went into the pits and changed two spark plugs, came in again on the seventeenth lap and on the eighteenth dropped to fifth position. At this time he was running on three cylinders and came in again, took down the motor and worked 2 hr. changing the wiring and installing another magneto.

With Resta out of the race, Wilcox again stopped in the twentieth lap when holding first position and asked to be relieved on account of sickness, which was permitted. His average up to this time was 87.14 m.p.h.

Aitken then took Wilcox's place, driving at top speed, his average at thirty laps being 86.6 m.p.h.; forty laps, 86.4 m.p.h, and forty-five laps, 86.08 m.p.h. In his forty-sixth lap he ran out of gas in the back stretch. He took on more gasoline in the forty-seventh lap and finished the forty-eighth lap at an average speed of 84.59 m.p.h., a new record for the Grand Prize.

After Aitken took Wilcox's place, Resta offered to buy Cooper's Stutz to get back into the race but the proposition was not made. Cooper drove a very consistent race. Resta, Aitken, Wilcox, Pullen and Ruckstell in Mercers and Rickenbacher in a Duesenberg passed him but he never varied the pace.

Rickenbacher relieved Weightman, taking his Duesenberg in the thirtieth lap, but failed to finish, although this was the only car running after the four winners had finished. Twenty-one cars started the race. Only three tire changes were made throughout the race, although the pit stops numbered thirty-three.

Fourteen starters in the Vanderbilt cup race used Rajah plugs, as did the first six finishers except Resta and Patterson. In the Grand Prize the same number of starters used Rajah plugs, and of those finishing all except Aitken and Patterson. Goodrich Silvertown cord tires were on the first four Vanderbilt winners and Goodyear cords on the first three in the Grand Prize.

Only one of the leaders in the championship award table made any appreciable gain in the Vanderbilt and Grand Prize events last week and he was Resta, chalking up 900 points when he won the first race. This brought his score up to 4100, just 660 ahead of his rival Aitken, who had 3440. Aitken, as explained in the previous paragraphs, did not gain a point. Cooper moved from eleventh position to sixth with a total score of 1045.

Vanderbilt Record Broken

Covers 294.035 Miles in Vanderbilt at 86.98 M. P. H.

SANTA MONICA, CAL., Nov. 16—For the second successive time, Dario Resta has won the Vanderbilt cup race, breaking the previous record by 11 m.p.h. The 294.035 miles of the road race was covered in 3 hr., 22 min., 48.4 sec., an average speed of 86.98 m.p.h.; the victory giving Resta the lead in the American Automobile Assn. $13,500 prize contest.

Though the three leaders broke the previous record of 78.72 m.p.h. for this course, made by Teddy Tezlaff in 1912, it was a race unmarred by serious accidents. At sharp noon nineteen drivers started the long grind over the 8.401-mile triangular course, before an audience of thousands. To the fourteenth lap it was a battle between Aitken, Cooper and Resta, with Resta steadily pushing to the front. At the fourteenth lap he took the lead, and after Aitken dropped out in the twentieth lap with a broken crankshaft, Resta maintained a steady pace to the finish.

Cooper came in approximately 8 min. behind Resta, with William Weightman, a Virginia sportsman, and a dark horse, running third in 3:42:00.4. The only other survivors were Clyde Roads, Vail and Patterson, the latter two being flagged while still running.

Mechanical troubles caused most of the eliminations, Bolden alone suffering from the dangerous turns. He skidded and went out in the twenty-first lap, and was the thirteenth man to quit. Eddie Pullen was disqualified on his thirtieth lap, while running fourth, because of an illegitimate stop for gasoline.

The race was well attended. On the straightaway temporary bleachers were erected facing the ocean. These were packed and the race was run through a lane of spectators around practically the entire course.

Up to to-day the Vanderbilt record was held by Ralph de Palma, made over the Santa Monica course in 1914, at an average of 75.6 miles per hour, though this was not the Santa Monica course record. Resta, in addition to acquiring additional laurels, added $4,000 to his winnings. Cooper received $2,000, Weightman, $1,000, and Roads, $500.

Smith Form-A-Truck to Enlarge

Will Form Truck Corporation with Issue of New Stock—Will Enlarge Production

NEW YORK CITY, Nov. 20—The Smith Motor Truck Corp. will be incorporated in Virginia shortly for the purpose of taking over the Smith Form-A-Truck Co., a Delaware concern. Announcement of the acquisition of this company by Michaelis & Co. and associates was made last week.

The new company will have a capital of 20,000 shares of 8 per cent cumulative and convertible preferred stock, redeemable at 120, of which 14,000 shares will be issued, and 1,200,000 shares of common stock, par value $10 a share, of which 1,000,000 shares will be issued.

A sinking fund of 5 per cent per annum will be established to retire the preferred stock at $120 or better, commencing Jan. 1, 1920, and the issue also is convertible, dollar for dollar, ten shares of common for one preferred, at the option of the holder at any time after June 30 next and prior to Jan. 1, 1920. After 8 per cent per annum has been paid on the common the sinking fund for the preferred will be increased to 10 per cent.

Issue of New Stock

The 14,000 shares of preferred and 1,000,000 shares of common of the new company will be issued for the property and business of the Smith Form-A-Truck Co. and in addition $830,000 cash is to be paid into the new corporation. The concern will have no mortgage or funded indebtedness outstanding, and none can be issued without the consent of the holders of at least 75 per cent of the outstanding preferred.

The present plant has a capacity of over 200 truck units a day. From Jan. 1 to Nov. 1 last the average production was over thirty per day. Sales are now running at the rate of about fifty units daily and it is estimated that by Jan. 1 next it will be manufacturing and delivering more than 100 units per day.

Unfilled orders and open contracts on hand on the first of this month amounted to more than 6000 truck units, and new orders are coming in at the rate of 100 per day. In 1917 the production will be at the rate of at least 30,000 units.

Net earnings for this year, estimating the last 2 months, will amount to about $1,000,000 more than eight times the annual dividend on the preferred, or a surplus after the preferred dividend equal to 25 per cent on the 1,000,000 shares of common.

The new company will have net tangible assets, exclusive of good will, patents, trade marks, etc., of $1,714,587, and net current assets of $1,410,454, equal to the outstanding preferred.

—

Elkhart Increases Capital

ELKHART, IND., Nov. 17—The Elkhart Carriage & Motor Car Co., this city, has increased its capital stock from $100,000 to $300,000 in order to take care of increased business. The issue is preferred stock bearing 7 per cent interest, payable semi-annually.

—

Steel Prices Higher

NEW YORK CITY, Nov. 21—Prices on automobile materials last week were for the most part steady with quotations on metals higher. Steel featured activities with a jump of $2.50 per ton. Bessemer and open-hearth steels are now quoting at $52.50 per ton. Fish oil rose 6 cents a gal. to 68, while linseed oil dropped 2 cents a gal. to 96. Rubber prices were steady. Para receded to 80 and Ceylon rose to 67½. The rubber plantations in Sumatra, Dutch East Indies, are developing rapidly. They cover an area as large as the island of Manhattan. One of the large tire companies owns a total of 93,759 acres on these plantations. From land which, less than a decade ago, had not a single rubber tree, this company is now receiving every month thousands of pounds of plantation rubber.

Empire Tire Refinancing

New Corporation Formed with $7,000,000 Capital—to Increase Production

NEW YORK CITY, Nov. 20—The Empire Tire & Rubber Corp. has completed negotiations for reorganization and refinancing by incorporating under the laws of the State of Virginia to take over the business of the Empire Rubber & Tire Co., established in Trenton, N. J., in 1887. The new company has a capital consisting of $1,500,000 7 per cent cumulative convertible preferred, par value $100, and $4,500,000 in common, par value $10, Of the authorized common $1,500,000 is to be reserved for the conversion of the preferred stock. The underwriting was done by Andrews & Co., this city, who are offering for public subscription $1,500,000 preferred, which is convertible into an equal amount in par value of common, ten shares of common for one share of preferred, at the option of the holder at any time after June 30, 1917, and prior to July 1, 1920. It is also offering for subscription the preferred stock with a privilege of subscribing to four shares of common at $4.50 per share, the common to be repurchased by the underwriting syndicate at $6 per share.

The company has recently increased its production to 1500 tires per day, and with a small additional expenditure this can be increased to 2000 tires per day. The sales of mechanical rubber goods now average about $800,000 per annum, and the new capital will enable a more vigorous manufacturing and sales policy so that the sales in this department should be doubled. New business of from $2,000,000 to $2,500,000, it is stated, will be had through the new affiliations, making a total, with the business it is now doing, of over $5,000,000 per annum, on which the company should show profits of $600,000 to $700,000, or approximately 12 per cent on gross sales. It is expected that the earnings of the company will approximate about six times the dividend requirements on the preferred stock issue, and about 18 per cent on the common after allowing for dividends on the preferred, amounting to $1,500,000.

—

Atlas Drop Forge Increases Capital

LANSING, MICH., Nov. 17—The Atlas Drop Forge Co. has increased its capitalization from $200,000 to $500,000. A 100 per cent stock dividend is being issued to all stockholders and $100,000 will be held as treasury stock.

The company was formed in 1906 with

a capital of $100,000 which was doubled in 1911. The plant is now producing to the limits of its capacity and according to present indications will manufacture $1,250,000 worth of their products for the coming year.

—

Madison Motors Stock Offered

ANDERSON, IND., Nov. 20—A part of the Madison Motor Co.'s $2,000,000 capital is to be sold in small blocks at $10 a share by H. M. Caldwell & Co., Indianapolis, sole distributors of the stock.

—

Dividends Declared

The Federal Rubber Co.; regular dividend $1.75 per share on second preferred stock, payable Nov. 25.

Ajax Rubber Co., quarterly of $1.25 per share, payable Dec. 15 to stock of record of Nov. 29.

Studebaker Corp., South Bend, regular 1¾ per cent on preferred and 2½ per cent on common, payable Dec. 1 to stockholders of record at the close of business on Nov. 20.

—

Truck Wheel Corp. Formed

CHICAGO, ILL., Nov. 21—The American Truck and Wheel Corp. of Chicago, which is capitalized at $1,000,000, has filed charter in Delaware to manufacture motor truck wheels, etc. The incorporators are William C. Loftus, John R. Cavanaugh and Ross J. Cavanaugh.

Motor Stocks Stronger

—

General Motors, Chevrolet, Maxwell, Miller, Firestone and Chandler Higher

NEW YORK CITY, Nov. 21—Automobile and accessory issues yesterday closed with a steady demand and higher. With the interest of investors centered in copper stocks, it was only natural last week that demand for automobile and accessory stocks should have lagged. As a sequel to this recession there has been a rather sharp drop in their prices. Prices, yesterday, picked up considerably and investors and speculators netted substantial gains on the up market under the leadership of General Motors which has reached 600, just 90 points higher than last week. Firestone Tire common has also strengthened and has gone up 25 points to 1375. Maxwell common surprised investors last week by suddenly jumping 4½ points to 76 on strength of the declaration of an extra dividend. General Motors was probably strong on account of the director's meeting held to-day at which directors are to be elected and from which a financial statement will be forthcoming.

Automobile stocks were comparatively quiet during the early part of the week. United Motors after a show of firmness eased off. There was a fairly good demand for Chalmers, which moved up about a point, but on realizing turned easier.

Powerful bear operations for several weeks have made two of the principal objects of their attacks Willys-Overland and Maxwell shares. The weakness in these issues has caused much selling. The short-selling interests, it is thought, have run their course, and the general decline in prices appears near a halt.

Pierce-Arrow preferred stock has been placed privately by the syndicate headed by J. & W. Seligman & Co. at 107 and the stock has all been sold. The New York Curb Market Assn. has listed 30,000 common shares and 15,000 first preferred shares, both of par value $100 of the Manhattan Electrical Supply Co.

—

Paige-Detroit Increases Capital

DETROIT, MICH., Nov. 21—The Paige-Detroit Motor Car Co. has increased its capital stock from $2,000,000 to $3,500,000 by the addition of $1,500,000 of 7 per cent cumulative preferred stock. The present capital consists wholly of common stock.

The new preferred stock is to be offered to the company's present stockholders at par and will have a par value of $100. The purpose of the new issue is to provide the company with larger working capital and enable it to carry larger stocks of working material on hand.

Overland Brings Out Sport Car

Four-Passenger Country Club Roadster To Ce Mounted on 75-B Chassis

TOLEDO, Nov. 21—The Willys-Overland Co. is now making deliveries of a new sport car which it has named the Country Club model. It is a four-passenger roadster embodying many unusual designs and constructed over the chassis used for the model seventy-five B., and sells for $695 f. o. b. Toledo.

The car is furnished with a rich gray body, with long grained upholstery and mohair top to match and has black fenders and trimmings, and red wire wheels. The two front seats are convertible and move independently forward and back to lengths suitable for the driver and his companion. The doors are of a wide Z shape and front hinged with pockets for tools and accessories. Rear seats for two are close up, but allow ample leg room for the occupants, so that four adults may ride comfortably in the car. Cantilever springs and special springs under the cushions provide for smooth and easy riding. The motor is a four-cylinder en bloc type with a 3¾-in. bore and a 5-in. stroke. Ignition is created by the battery and distributer system and the Tillotson carbureter receives the fuel by vacuum feed. A 12½-gal. gasoline tank is situated under the rear dash. The car has a wheelbase of 104 in. and includes in its equipment an extra wire wheel and a spare tire bracket.

Paterson Adds "Chummy" Roadster

FLINT, MICH., Nov. 20—The W. A. Paterson Co. will have a single-chassis model for 1917 carrying two bodies, one a regular touring model and the other a newly designed "chummy" roadster. The touring model has a new body with a double cowl, and it is somewhat longer and wider. The "chummy" roadster is mounted on the same chassis, having a wheelbase of 117 in., and its capacity is four passengers.

Fight Attempt to Increase New York Truck Fees

ALBANY, N. Y., Nov. 21—The commission for creating a higher schedule of fees for motor omnibuses and motor trucks in New York State held its first public hearing in the Capitol to-day. The commission has not made public any of its recommendations as yet and the hearing here to-day was for the purpose of enabling it to obtain first-hand information and suggestions from owners and operators of motor trucks.

The commission consists of Edwin Duffey, Highway Commissioner; W. W. Wotherspoon, Superintendent of Public Works, and Frank M. Williams, State Engineer. It was formed by the last legislature to scientifically determine a new schedule of registration fees for motor trucks and omnibuses, such schedules being based on the time and extent of use, and wear and tear of public highways by such vehicles.

From the arguments presented by Charles Thaddeus Terry, representing the N. A. A. C. and the Automobile Trade Assn. of New York; Roderick Stephens, George H. Pride, Oscar W. Shadbolt and A. F. Masury of the Motor Truck Club of America, and others, it was brought out that as the State only has jurisdiction over State roads and not city, county or village roads, any fees based on the wear of public roads meant State roads and that these fees could only be placed on those trucks using State roads.

Empire Inclosed Car Ready Dec. 1

INDIANAPOLIS, IND., Nov. 20—The Empire Automobile Co. has entered the field of inclosed cars with a sedan which will be ready for delivery Dec. 1. It is a convertible inclosed type with two doors, one on each side midway of the body so that the front seats are reached by an aisle way. The upholstery is gray and black Bedford. Two cellarettes or small package compartments are behind the rear seat cushion. The body is mounted on the six-cylinder 120-in. wheelbase chassis.

Ball & Ball Co. Incorporates

DETROIT, MICH., Nov. 21—The Ball & Ball Carburetor Co. has incorporated for $20,000. Incorporators are F. H. Ball, F. O. Ball and Kate D. Ball. The concern was formerly a partnership of father and son and has been made into a corporation because of the entrance of a brother as a partner. The company sells all of its product through the Penberthy Injector Co.

$412,812 Awarded to H. S. Chapman

CLEVELAND, Nov. 21.—An award of $375,000 and interest, amounting to a total of $412,812, has been made by jury here to Henry S. Chapman in his suit for $800,000 alleged to be due him from the Peerless Motor Car Co. Mr. Chapman, who had no previous connection with the automobile industry, claimed the violation of a contract under which he went to London to sell motor trucks to the British war department.

Gillam Co. Plans Capital Increase

CANTON, OHIO, Nov. 22.—The Gillam Mfg. Co. will increase its capital Nov. 28 from $350,000 to $450,000 for the purpose of extending its factory. The Gillam company manufactures materials for Packard, Maxwell, Overland, Haynes and Oakland.

Springfield Body Sues Fisher

Charges Infringement of Two Design Patents Covering Two of Its Body Types

NEW YORK CITY, Nov. 21—The Springfield Body Corp. and the Springfield Body Co. have brought suit against the Fisher Body Corp., the Fisher Body companies and F. J. Fisher and A. Mendelson, the latter controlling interests in the Fisher Body interests, charging infringement of design patents No. 47,252 and 47,630, covering the Springfield type convertible and four-door bodies, respectively. Charges of unfair competition are also brought against the defendants, who are sued individually and collectively. Under its patents the Springfield corporation claims exclusive right to produce and market bodies of these types, and alleges that the defendants have incorporated elements of the designs covered by these patents in their product.

The Fisher Body Corp. will contest the claims of the Springfield interests, President F. J. Fisher stating, "We have been advised by the best patent counsel we can get, and they have confirmed our absolute belief that there is no infringement whatsoever. Had we ever thought we were infringing, we certainly would have abandoned that line of business, as it does not constitute over 2 per cent of our entire business."

Last February the Springfield Body Corp. of New York was formed, controlling the Springfield body patents. Since then the following twenty-three companies have taken licenses to manufacture the same on a royalty basis:

Chas. Albresch Co.	Milwaukee, Wis.
Hume Carriage Co.	Boston, Mass.
M. Armstrong Co.	New Haven, Conn.
Millspaugh & Irish.	Indianapolis, Ind.
Blue Ribbon & Carriage Co.	Bridgeport, Conn.
J. W. Mount Co.	Red Bank, N. J.
Cadillac Motor Car Co.	Detroit, Mich.
Staver Motor Car Co.	Chicago, Ill.
R. N. Collins, V. W. Co.	St. Louis, Mo.
Glascock Mfg. Co.	Muncie, Ind.
Hale & Kilburn Co.	Philadelphia, Pa.
Alexander Wolfington's Son.	Philadelphia, Pa.
Portland Body Works.	Portland, Ind.
Central Mfg. Co.	Connersville, Ind.
Racine Mfg. Co.	Racine, Wis.
Chas. S. Gaffery Co.	Camden, N. J.
W. S. Seaman Co.	Milwaukee, Wis.
Chicago Coach & Carriage Co.	Chicago, Ill.
E. J. Thompson Co.	Pittsburgh, Pa.
FitzGibbon & Crisp.	Trenton, N. J.
Victor Mfg. Co.	Detroit, Mich.
Walker-Wells Co.	Amesbury, Mass.
Willys-Overland Co.	Toledo, Ohio

Among the automobile companies which are now incorporating Springfield type bodies in their regular output are: Apperson, Abbott-Detroit, Cadillac, Chandler, Cole, Davis, Haynes, Inter-State, Jordan, King, Marmon, Mitchell, National, Oldsmobile, Overland, Paige-Detroit, Premier, Reo, Standard, Stearns-Knight, Studebaker, Velie, Westcott, Winton and Willys-Knight.

N. A. A. A. J. Meets in Boston

Final Session in New York—Action Routine Matters

BOSTON, MASS., Nov. 21—*Special Telegram*—The Ways and Means Committee of the National Assn. of Automobile Accessory Jobbers opened session to-day. The meeting will be continued to-morrow and final session will be held at the Hotel Astor in New York on Thursday. Only routine matters are being taken up and final action on the suggestions of the committee will be deferred until the meeting beginning Jan. 10. To-day's session was exclusively for members of the committee, the gathering being called by W. M. Webster. To-morrow there will be an open meeting at which New England jobber members and jobbers who are not members will attend. Non-members will be invited to join the association. Those in attendance to-day are W. K. Norris, McQuay-Norris Mfg. Co.; Wm. Sparks, Sparks-Withington Co.; S. B. Dean, Nichols, Dean & Gregg; F. B. Caswell, Champion Spark Plug Co.; George W. Shafer, W. E. Pruden Hardware Co.; W. W. Lowe, Electric Appliance Co.; Mr. Moody, Boston, and W. M. Webster.

Inter-State Sues Rutenber

DETROIT, MICH., Nov. 20—The Inter-State Motor Co. has started suit for $700,000 against the Rutenber Motor Co., charging breach of contract. It is alleged that 3000 motors contracted for caused the purchase of $2,000,000 worth of parts and the booking of orders for 5000 cars, and the Interstate company alleges that only 379 motors were delivered.

—

Brush Analyzes Crankshaft Balance Before Indiana S. A. E.

INDIANAPOLIS, Nov. 21—At a meeting of the Indiana section of the S. A. E. held here last night, A. P. Brush read a paper which was really a continuation of the one he presented at the summer meeting of the Society. Starting where the former paper ended, Brush pointed out that there are two sorts of engine vibration; that due to reciprocating and other unbalanced forces which tend to move the engine as a whole, and those which tend to oscillate internal parts without affecting the whole mass directly. In the latter class come crankshaft deformations, whether caused by bending or torsional stress.

Brush drew attention to the fact that the crankshafts of four- and eight-cylinder engines need counterbalance masses much more than do six throw shafts, and he expressed a doubt as to whether a large size of shaft was not a better solution of the vibration problem than a balanced shaft, except for four throw shafts where bending is a more important question than torsional deformation. He placed special stress on the fact that balancing a shaft does not affect the loads on any crankpin bearings or on the small end connecting rod bearings, it merely prevents vibration and lessens the load on the main bearings.

The paper was illustrated with diagrams showing the forces within an engine and Brush concluded it by a plea for his patented system of lubrication described in the summer meeting paper.

—

Brooks with Madison Motors

DETROIT, MICH., Nov. 21—H. H. Brooks has been appointed superintendent of agencies for the Madison Motors Corp. Mr. Brooks was formerly sales and advertising manager for the Pontiac Chassis Co.

—

General Motors Builds Plant

DETROIT, MICH., Nov. 21—The General Motors Co. is erecting a one-story factory 734 by 200 ft. The building will be used for the manufacture of motors for use of affiliated companies of the General Motors, the output of the Northway Motor & Mfg. Co. having proved insufficient.

The site was originally planned for use for the Cadillac company's new plant, but different arrangements followed the purchase of another site last week by the Cadillac company.

—

Livingston Shell-and-Hood Patent Upheld

NEW YORK CITY, Nov. 21—In a decision handed down here yesterday, the Livingston patent No. 1,156,017 covering a mask for concealing the engine and radiator casing of a car was held valid and infringed by the Lawco radiator shell and hood made by the F. H. Lawson Co., Cincinnati, Ohio. The construction covered by the patent comprises a motor hood section and a separate removable radiator hood section, the assembly having streamline tendencies when mounted on a car.

The suit was brought by D. McRa Livingston and his licensee the Ospeco Mfg. Co. against the Lowe Motor Supplies Co., charging that the Lawco device sold by the Lowe Company and manufactured by the Lawson concern infringed the Livingston patent. Judge Sheppard commented that no wilful infringement was evident but that the Lawco construction was so similar to that specified in the patent that he could only hold the latter infringed. The suit was in the U. S. district court for the southern district of New York.

Synthetic Resins Discussed

Dr. Baekeland Lectures Before Detroit Chemical Society on Bakelite

DETROIT, MICH., Nov. 17—Dr. L. H. Baekeland, president of the General Bakelite Co. and a member in an advisory capacity of the Hooker Electric Chemical Co. of Niagara Falls, lectured last night on the subject of "Synthetic Resins" before a joint meeting of the Detroit Chemical Society and the Detroit Engineering Society at the club rooms of the latter organization.

He told of the application of synthetic resins in electrical and automobile engineering, stating that bakelite is a concentrated product of formaldehyde and carbolic acid, and that only one special condition can be present when it is formed, and that when this condition is not present anything but bakelite will be the result, and added that instead of using phenol, its homalogues, cresols, other phenolic bodies and various substances having the same functions may be utilized.

"It should be well understood," said Dr. Baekeland, "that formaldehyde in reacting about phenol does not necessarily give bakelite. Quite to the contrary. It is only under very special conditions, now well established by public research, that this substance can be obtained. When formaldehyde is left to react on phenol under ordinary conditions, almost anything may happen but the formation of bakelite. In some cases a resinol material is formed, but it has no especially new properties and is similar to cheap natural resinol."

—

500 S. A. E. Banquet Tickets Sold

NEW YORK CITY, Nov. 20—The number of tickets for the annual banquet of the Society of Automobile Engineers on Jan. 11 at the Hotel Biltmore is becoming scarcer each day. Fifty tickets have been sold since last week, bringing the total sale up to 500. Capacity is 750.

—

Stutz Wins Phoenix Race

PHOENIX, ARIZ., Nov. 18.—R. H. Delno, of Tucson, driving a Stutz, won the 100-mile free-for-all race at the Arizona State Fair here to-day, in 1 hr., 43 min. and 12 sec. E. F. Bennett, of Silver City, N. M., and also driving a Stutz, won second money in 1:45:01. A. Gladney, driving an Overland entered by the Arizona Overland Co. of Phoenix, was third in 1:45:10. Tom Brewer, of Globe, Ariz., driving a Marmon, finished fourth in 1:46:20. C. G. Miller, driving a National, finished fifth in 1:48:56 2/5.

International Competition

THE uniting of different concerns in the same industry for promoting the use of U. S. A. goods abroad will unquestionably have to be resorted to when war days are over and all Europe takes up anew the various channels of export trade which it held previous to the war but has been forced to relinquish during the war. Such co-operation of firms in the same industry is in export circles known as international competition, a term new to many exporters in our industry.

It is only natural that those countries that have been forced to drop export trade temporarily during the war will enter the field with renewed efforts as soon as peace is declared. The war is believed by many to be almost entirely a trade war. If it is worth while these European nations expending so many billions fighting for trade privileges, it is a correct conclusion to draw that they will fight with equal vigor in trade circles to win back what has been lost.

While some export authorities contend that European nations will be so exhausted after the war that they cannot take up with vigor the export work, the general feeling is otherwise. Why fight so strenuous and costly a war for trade only to be so weak when the fray ends that you cannot take advantage of what you have been fighting for? All the energies of these countries will be thrown into foreign trade. They will only be losing their remaining business life blood if they let the thing go unchallenged that they have been fighting for.

After the war international competition will be many times more intense than before the war seems but a natural conclusion. Travelers from foreign lands constantly report that when fighting is over the buyers will turn to European countries for their goods, where they have been buying them for over a generation and, in some cases, for three generations.

Europe is many times better organized to-day than before the war. While human loss has worked a handicap, remaining resources have been so superiorly organized as to largely make up for the loss in labor. Factories have been doubled and often trebled; modern production methods have been installed, and Europe has grown in 30 months more than in 30 years of peace.

The Year in Tires

THE tire industry is keeping step with the automobile industry in production, and its experimental departments are as busy as the engineering departments of the automobile factories in improving quality and methods for increasing production. Many of our large tire concerns merit congratulation for the wide-gage policy of research they are carrying on. It is solely due to such work that tire quality has been on the increase, and the amazing results given in racing tires of the season just closing is good proof of what has been accomplished in improving the chemistry of tires.

A new movement and one that gives promise of good results is that of building a better-balanced tire, one with a fifty-fifty relationship between carcass and tread when wear is the criterion. The heavy rubber tread is useless if the carcass is not built to give approximately the same service. There is no economy in a tire with a 10,000-mile tread and a 3000-mile carcass. The ideal tire is one with a carcass so balanced in strength and endurance to give the same wear as the tread. In solving this, tire-makers have carried on a world-wide campaign of investigation. Used tires from all fields of service have been collected and experimental departments are doing all possible to arrive at the proper amount of carcass to go with the proper amount of tread and vice versa.

Tire-makers have not made as much progress as desired in reducing the number of standard tire sizes. Each year sees a wider effort to reduce the number of so-called standard sizes and also to reduce the number of so-called oversizes. The end is not yet in either case. The work has not gone forward so well as that of standardizing many parts entering into the chassis. The introduction of cord tires is greatly increasing the number of sizes, and with the field split between Q. D. clinchers and straight-side types the number of sizes to be carried is still far too large. The argument between straight-side and clincher will eventually solve itself, but a good getting together of tire makers might end it in a single year and thus make the selling of tires much easier.

The Tire Industry

¶ Increased manufacturing facilities the great spotlight of the year—Tire production keeps pace with automobile production.

¶ Cord tires now being produced in quantity by several concerns.

¶ The balanced tires now aimed at by tire makers.

¶ Fabric cost has increased 100 per cent—chemicals also are more expensive—crude rubber has been plentiful.

¶ Greater use of non-skid types.

¶ Tire companies are leaders in welfare work among employes.

HISTORY will record 1916 as being a banner year in the tire industry. Every tire factory is literally swamped with business. Output figures have increased from 50 per cent among the large producers up to 2000 per cent with some of the smaller over 1915. Factories are being built almost universally by existing tire concerns to add to their present facilities and large new concerns are entering the business on a heavy scale.

Millions of dollars' worth of new machinery has been bought to supply the hundreds of acres of increased floor space. Manufacturing schedules that reach into the millions are planned by the larger concerns, and even with this great output they are straining every resource to catch up with demand by improving methods and adding space and machinery.

With this increase in business, quality has also gone up. More secrets have been learned in the laboratories and employed with benefit to the quality of the product. Better mileage figures are being obtained by users. The difficulties of the last year in the crude rubber market have been cleared away and now no difficulties are found in obtaining the raw material.

Prices Have Not Risen

In spite of advances of 100 per cent in the prices of fabric, of increased cost in almost every item of material and manufacture, prices to the consumer have not risen. Better tires for the same money, in spite of the increased costs, tells the story of increased efficiency in factory methods and the benefit of quantity production. Several well-defined trends are apparent, and these form an interesting story of development.

Cord Tires a Growing Issue

Cord tires are a growing issue of the year in the industry. Although more expensive than the fabric, they are being used all over the country and are recognized as a desirable part of regular automobile equipment. This tendency is expected to grow, until, it is the belief among tire manufacturers, it will strike to about the $1,800 level in cars. While only two or three concerns are marketing the cord type in quantity, there are several companies experimenting with it, and it will not be surprising to have many different makes on the market during the next year.

Naturally the reason for the cord tire is its greater resiliency, longer life, possibility of standing lower inflation pressure without damage, and in general, aiding in the production of that very desirable goal always in the eye of the tire builder, the balanced tire.

Cord tires are in two general classes. There is the cable tread, such as is used in the Silvertown cords, and the thread system, such as is used in the Goodyear. The names are suggestive of the basic differences. The cable system is a card carcass built up of multi-strand cables, which have rubber cores. The thread system has the cords in the form of a fabric, for convenience in manufacture. The cords are held in place by a few very fine cross threads, which break when the tire is used, this leaving only the cords.

The Balanced Tire

By the balanced tire is meant one which maintains an even balance between carcass and tread. Samples of used tires that have failed are gathered from all parts of the world by the important tire builders, and the reasons for failure are gone into. If the carcass has perished through normal wear, and yet there remains a considerable amount of tread rubber has not been worn away, the tire is not balanced. The two should be exhausted at the same time, or nearly so, and the time-worn example of the one-horse shay represents the cynosure of the tire developer, the world over.

When it is stated that this year's tires are better balanced than previously, it means much to the manufacturer, and it also bears a very natural profit for the user, because the saving which the balance means to the manufacturer is reflected in lower cost of materials and finally in reduced price possibilities.

The reason that the cord tire is generally a superior article in the way of balance is that the carcass is the limiting factor and the cord tire is capable of withstanding a great amount of flexure in the side wall. Tire carcasses fail under flexure because in bending the side wall one part is put under compression, while the other is in tension. This tends to cause a split along the neutral axis. With the cord type the entire carcass is more of a single unit, which resists to a maximum degree any tendency toward separation of the plies.

No one in the tire world sees any prospect of cord tires prices being down around the level of fabric prices for years. In fact, unless some revolutionary method of manufacture is developed, which is not yet in sight, this state of affairs will not be altered. It is a question whether or not the cord tire

is cheaper on a per mile basis for the user. It certainly will stand a maximum amount of neglect and a lower inflation.

Two Methods of Curing

There are two general methods of curing tires; one is where the entire product is cured at once, which is known as the single cure, and the other in which the carcass is first given a partial cure, the tread then added, and the entire casing then cured together. This is the double-cure process. Both these are used extensively and there has not been any gain by either method during the year.

Straight Side vs. Clincher

Another great point is the controversy of straight side versus clincher. The clincher tire is favored abroad, and for that reason American export products have to be made in this style. For domestic trade the straight side is growing rapidly, and if Ford sizes are excluded, it is probable that the percentage of straight side, as compared with clincher, is about 75 to 25. The soft-bead clincher is rarely seen above the 3½-in. size. The Q. D. clincher, or non-extensible bead type, is seen in the larger sizes, but, as compared with the straight side the percentage is dropping annually.

The criticism leveled against the straight side on the safety basis does not seem to have justified itself in the light of development. For example, Goodyear is making straight side tires in 6, 7, 8 and 9-in. sizes, which have 100 per cent perfect record as regards resistance against fastening failure. As a manufacturing proposition, the straight side is on a par with the clincher.

The Compounding Work

One of the points which the public does not appreciate in tire manufacture is the work of the compounding room. It is here that the secrets of chemistry are studied for the purpose of improving the compounds used for various parts of the tire. A mistake in the compounding room would cost 6 months in production if it were a serious one, and naturally conservatism and care are the watchwords of the tire laboratory.

Considerable talk has been going around regarding tread colors, but the gist of the entire matter seems to be that the compounding room can furnish about any color desired. and at the same time have about the same degree of toughness. It is quite certain that the black tread is very popular just about now, and taken in conjunction with the red side wall this gives a very attractive appearing tire, which is used by many of the large manufacturers. The important result from the car drivers' standpoint is that improvements in compounding during the year have given a tougher tire tread for the same price. Truck tires, too, are better because of superior compounding methods.

In the pro and con arguments for and against the straight side type, the majority on the side of the straight side seems to sum up its arguments under four main heads.

First, the line of weakness just above the bead in a clincher tire is eliminated in the straight side, or to put it in other words, rim cutting is reduced.

Second—The straight side tire has a broader base, and is, therefore, a more stable mechanical proposition; there is less tendency for the tire to roll off the rim, although it is doubted if this were ever noticed to any great extent even in the clincher type. This broader base is included in the argument that better disposition is made of the air space with the straight side tire. There is greater air space.

Third—The radius of flexure at the rim is large. This naturally is a factor in prolonging tire life, as the smaller the radius of flexure the more severe are the stresses which tend to separate the fabric plies and hence cause the tire to disintegrate.

Fourth—The continuous non-extensible bead. This is made up generally of a core of piano wire. In some instances the piano wire is braided to give it even a stronger assembly. This piano wire binder running continuously around the bead gives the non-extensible feature, which can be employed in the straight side tire, but which, of course, is out of the question in a soft bead tire, which must be stretched over the rim, although used in a Q-D clincher.

1916 a Wonderful Year

All told, 1916 has been a wonderful year in the tire business. On every hand business is reported increased by great percentages. Firestone output increased 62 per cent. during the year. The output of Goodyear has increased 85 per cent; Goodrich has increased 40 per cent; Miller Rubber Co. reports approximate increase of 150 per cent; in the New Jersey district Ajax, Michelin, Endurance, Carspring, Howe, Thermoid and Braender have felt the reaction from the greatly increased production of automobiles, and the last-named concern alone reports an output increase of 200 per cent. Besides the unprecedented demand, the advantage of excellent crude rubber market conditions has prevailed, and although every item of manufacture has increased in cost from 20 to 300 per cent, according to one concern, and varying percentages according to others, the increased production has largely overcome the increased cost.

To meet the increased demands, acres of floor space have had to be added, and more efficient machinery substituted. There is not a concern which has not felt the necessity for increasing its floor space, machinery, labor or output facilities. Some of the increases in area are interesting. Firestone has added 11 acres, Goodrich 21 acres, General Tire & Rubber has large areas now under process of building, Braender has added 10,000 sq. ft. The story of the Jersey company is the same. Michelin, Thermoid, DeLion, Acme, Ajax, and all the others in the scattered tire territory throughout the entire United States have shown the reflection of the demand for increased production. Other examples showing the general growth throughout the country are an increase in output of the Gorden Tire Co., which increased its output 50 per cent, and added 3000 sq. ft. of floor space. The Gibson Co., Indianapolis, increased 125 per cent; the Alliance Co., Alliance, Ohio, 50 per cent; the Acme Rubber of Trenton 25 per cent.

The Multiple Calendering Process

In adding new machinery it is quite natural that a number of manufacturing processes would be improved by the use of more modern machinery. One of the points in which manufacturing has been conspicuously improved is in the multiple calendering process. In making the fabric for the fabric tires a roll of the fabric is run through the calender and another roll of rubber passes through and impregnates the fabric with the rubber. It is then reversed and impregnated from the other side after which it is run through rolls again and a surface coat of rubber applied to it. With the old method, it was necessary to run the roll of fabric through the machine three times, once for each impregnation and again for the coating. With the new method a train of three calenders, placed one after the other, allows the material to be fed continuously from one to the next so that by the time it has passed through all three it has been given the two impregnations from the first two machines and the coating from the third. This avoids two shutting down processes between each roll of fabric and avoids two restarting actions in again circulating the fabric through the calenders.

Less Reclaimed Rubber

With the advantageous crude market a less percentage of reclaimed rubber is finding its way into tires and the number of low grade tires manufactured is decreasing in proportion to the total. Also during the year there have been a great

many outlets which have sprung into being for the lower grades of tough rubber stock. These are not necessarily poor grades of rubber but are not of the same quality as is necessary for pneumatic and solid tire use. A good example is in the rubber soles of shoes. This white rubber compound has increased remarkably and a great many of the concerns manufacturing tires turn their attention to this field also.

Fabric Cost Doubles

Fabric cost has doubled during the year. Firestone reports a 100 per cent increase and others very much the same. It must be remembered in thinking of the increase in fabric prices that the cord prices have kept pace with them, so that on the whole it can be stated that cord tires are 20 to 30 per cent more expensive than the fabric type. The chemicals used in the compounding room have gone up in price, but even taking this into consideration the improvements are very noticeable in this department of the work. It is difficult to obtain access to the compounding room of a rubber factory, but there have been rumors which are quite well substantiated that several chemicals which were hitherto deemed impractical for rubber compounding work have been found available. The result has been particularly noticed in toughness and ability to resist abrasion.

Firestone has embarked in the cord tire field and is turning out daily 500 of this type. The daily production of the fabric tire is 12,000. These are all machine-made and during the year $1,500,000 has been spent in machinery. Like other companies, Firestone reports the crude market to be satisfactory and in the manufacture of tires the percentage of 70 per cent plantation against 30 per cent wild rubber is used. As one of the leading tire organizations the indorsement of this concern of the black tread tire with the red side wall has helped in putting this development among the foremost trends of the year. The non-skid tire made by this oncern is well known on account of the printing of the word Non-Skid across the tread on the fabric tire. On the cord tires the double F non-skid tread is used.

Goodrich is producing about 20,000 tires a day. All of these are, practically speaking, manufactured by machinery and during the year a great amount of money has been expended on this part of the equipment. The testing department has been given special attention in the development program.

Non-Skid Types Gain

Owing to the growing practice of car manufacturers in equipping the rear wheels of their product with non-skid tires the percentage of the total output in non-skids is increasing in all plants. During the year 1916 75 per cent of Firestone tires were non-skids. The price of these to the user is 12½ per cent higher than the plain tread, while the price of the cords is approximately 25 per cent higher. About 25 per cent of the output is straight side.

In securing the supply of crude, 60 per cent comes from the East Indies, about 30 per cent from Brazil and the remainder from scattered territories. Although minor structural changes have been made to improve the product, there have been no radical changes in design of either the fabric or the Silvertown cords. The most important improvement is the addition of straight side tires in the Silvertown cord models, thus completing the line.

Tire Companies Increase Activity

PRACTICALLY no change appears in the Michelin line this year. The company's newest model was brought out only about a year ago, this being the Universal non-skid casing which is made with both clincher and straight side bead. Additions to the factory have been going up throughout the year and a large three-story building has been started which will nearly double the capacity of the plant. Lack of manufacturing facilities has proved a considerable handicap to the company during the past year, and great difficulty was experienced in securing molds. The latter problem was solved by the Michelin company making its own molds, so that it now has a complete line, including the popular 30 by 3½ size. In the tube department a unique installation is the circular mold upon which the red rubber inner tubes are made. This conforms to the shape of the tire casing, and the company claims that the tube is thus in normal shape when inflated.

Woodworth Has New Tread

A new non-skid with diagonal depressions each side of the center of the tread has been adopted by the Leather Tire Goods Co., Niagara Falls, N. Y., maker of Woodworth Trouble-proof tires. This design replaces the non-skid in which circular depressions were used. The feature of this tire, which is also made with plain tread, is that there is a strip of leather surrounding the casing of the tire and under the tread. It is designed to be puncture and blow-out proof, and is guaranteed for 5000 miles. The leather is chrome tanned and specially prepared so that it will not interfere with the resiliency nor cause heating or other difficulties. Its purpose is to add materially to the strength of the tire. About 55 per cent of the production is non-skid tires and the rest are plain tread. Non-skids are more popular in the North and plain tread in the South. About 27 per cent have straight sides, 8 per cent Q. D. and 65 per cent clincher. Straight-side tire business has increased about 20 per cent. Trouble-proof tubes are also built, and are made of several plies of rubber with the grain of alternate plies running crosswise so that the tube has equal strength in both directions.

Carspring Increases Mileage Guarantee

The Carspring tire, made by the New Jersey Car Spring & Rubber Co., Jersey City, N. J., is improved in detail with the result that the guarantee has been increased from 3500 to 5000 miles. It is made both as a non-skid and plain tread and red tubes are manufactured. Sixty per cent of the casing production is non-skid and 80 per cent of the casings, with the exception of the Ford size, are straight side. Cord tires are not manufactured.

Republic Favors Black Tread

As a good example of the proportion of non-skid to plain tread, Republic makes 75 per cent of the total output non-skids. They are made with black tread only and a distinct advantage is claimed for this tread stock. The tires are machine made. Another Republic feature is the long guarantee basis, 5000 miles. This concern verifies the straight side trend, stating that it sells best up to the 4½-in. size. This is significant in view of the tendency toward straight sides even in tires of larger section and shows that everyone is not as yet satisfied that the straight side tire is best in the larger sizes.

Kelly-Springfield Specializes on Non-Skid

Kelly-Springfield tires are 80 per cent non-skid. It is a single-cure tire and reflects the straight side tendency, as about 75 per cent are made in this style. Kelly-Springfield adjustments are made on a 6000-mile basis on the non-skid and 5000 mile on plain treads. There are two plants,

one at Akron and one at Wooster, Ohio, the latter making Ford sizes only. The present plant has grown about to its capacity and the company has recently purchased land at Cumberland, Md., where a new factory will be erected.

Pennsylvania Makes Many Straight-Side

Three styles of Pennsylvania non-skid tread are marketed, each with a different mileage guarantee. The Vacuum Cup has 6000, the Ebony tread 5000, and the Bar Circle 4000. All three are the same in materials, but differ in the tread shape and thickness. They are all single cured. The experience of the Pennsylvania concern bears out the statement that 75 per cent of all tires for 1916 exclusive of the Ford size are straight side. The Pennsylvania tire is sold principally to dealers and hence the percentage of straight side output is significant of current demand.

Redwall Now Made on Full Mold

The National Rubber Co., Pottstown, Pa., which makes the Speedway Redwall tires, has changed from the wrapped tread to the full mold process. It claims that the full mold tire has a greater density and resistance than the wrapped method due to the higher pressure during vulcanization. To be specific, wrapped tread tires are cured at a pressure of from 750 to 900 lb., whereas the full mold tire is cured at 2250 to 2500 lb. per square inch. The entire National output is fabric tires, all being hand made. This concern is growing rapidly, the factory output having increased approximately 2000 per cent during the year. In area this amounts to about 60,000 sq. ft., and during next year 70,000 sq. ft. additional is contemplated.

Thermoid Specializes on Fabric Tires

Thermoid is specializing on fabric tires and does not contemplate the manufacture of the cord type. The company does not make any clincher tires above 32 by 3½. Both hand and machine work are used, with the machine generally on the small sizes and the hand methods on the large. On the other hand, there are several Jersey concerns which are preparing to manufacture cord types.

Fisk Factory Covers 29 Acres

Fisk tires have been slightly refined, but in the main are the same as heretofore. Non-skid pneumatics are manufactured under the trade name of Red Top, and there is also a gray non-skid. Gray smooth-tread tires are also produced. Production has been increased about 25 per cent during the year, the factory additions including a large mill building, storehouse and seven-story administration building, bringing the total floor area of the plant at Chicopee Falls to 29 acres. New machinery to the value of $425,000 has been installed during the year.

Combination Features Hold-On Tread

The Combination Rubber Mfg. Co., Bloomfield, N. J., reports the production of 130,000 tires and 145,000 tubes during the year. The Hold-On tread, a depressed type of non-skid, accounted for 90 per cent of the production; 40 per cent of the tires are straight side and the manufacture of tubes is almost equally divided between gray and red, the latter being an antimony-cured, hand-made product. All tires are wrapped tread. It is not expected that there will be any appreciable advance in the prices of the product, inasmuch as the company is protected by favorable contracts on fabric and rubber.

Braender's Many Improvements

Braender is not making any cord tires and the percentage of fabric tires manufactured by machinery is about equal to that manufactured by hand.

During the year the improvements in Braender tire manufacture run through the entire gamut of treads in tire design. A tougher tread, a better balanced product, improved fabric weave, improvements in calendering and greater strength in friction and cushion rubber are among the principal points where progress has been made. In addition, there is now special waterproofing on the inside of the tire to prevent water from getting into the fabric. The new form of breaker strip of heavier construction and basket weave increases the number of rubber rivets which hold the tread to the fabric and gives an extra tough construction which resists the danger of tread stripping. In the Braender, as well as in many other tires, the side walls have been made tougher to protect the carcass from ruts and sandy roads.

Quaker City Features Clinchers

Quaker City is now producing a single cure non-skid tire. About 75 per cent of the output is in clincher sizes. Factory buildings have been greatly increased and production accordingly put up during the year.

Converse Triple Tread

The triple tread made by the Converse Rubber Shoe Co. of Malden, Mass., is guaranteed for 6000 miles and is made in any of the popular sizes. The triple tread tires are cured by the unit wrapped method with a single cure.

The Endurance Rubber Co. manufactures all non-skids. The Rubber Insulated Metals Corp., making the Century tire, makes 75 per cent non-skids.

Guarantees vary with the different policies and with different constructions. A few of these have been mentioned varying all the way from 3000 to 6000 miles, but it cannot always be said that the guarantee gives any valuation of the data on the value of the tire. The purchaser may be spending a certain percentage of his money for guarantee and the rest for tire, which would depend on the quality of the product and its life.

Ajax Uses Single Cure

Ajax uses the single-cure process for its entire output and is producing 1700 to 1800 tires a day. It is adding new space. A significant point in relation to the straight side question is that Ajax states that 75 per cent of its business outside of the Ford sizes is straight side.

Empire Makes Cord Tires

Empire has its cord tire on the market and expects that this type will form a considerable percentage of the 1000-a-day output. Of the Empire output 60 per cent are straight side and the percentage is increasing.

Lee Has Armor-Plated Type

Another concern which has more than one style of non-skid tread is the Lee Tire & Rubber Co., which makes a puncture-proof style with metal disks forming an armor plate in the carcass beneath the tread. There is a plain rubber non-skid without the metal disks. One of the improvements is that the side cover strip is continuous and integral with the tread.

Acme, Delion and Globe Wrap Treads

Both the wrapped and molded tread are produced by Acme also, while Delion and Empire have one method solely. Delion uses all single-cure, wrapped-tread, while Empire has single-cure molded. Another concern which produces only the wrapped tread is the Globe Rubber Tire Mfg. Co. Here the single-cure process is used and some of the tires are made by hand and some by machine.

Rutherford Makes Black Ribbed Tread

The popularity of the black ribbed tread which made its appearance coincidentally with the cord tire has caused some concerns to outfit their plants to produce a tread of this sort for fabric tires. This tread is faster than a great many of

the plain treads and is also of good appearance. One of the treads brought out along these lines has been put on the market by the Rutherford Rubber Co., under the name of Sterling. The red side wall which has proved popular is also used.

Miller May Make Cord Tire

Although no definite information is available regarding the intentions of the Miller Rubber Co. on cord tires, it is probable that early announcements will be made. This concern features a non-skid known as the Geared-to-the-Road tread. The straight side business has increased and at the present time 33 per cent of the total output is devoted to this type. This concern will have turned out 300,000 casings during the year 1916, and in 1917 will manufacture, according to present expectations, 500,000. The tires are made in all sizes, including millimetric.

Hood's Arrow Tread

The Hood Rubber Co. has an Arrow tread representing 75 per cent of its output. This is a single-cured job which has not been altered during the past year. Production schedule has shown an increase toward the straight side and the total capacity of the plant has been doubled and will probably be quadrupled next year. Both red and gray tubes of equal quality are manufactured.

Knight Uses Black Side Walls

It seems to be quite true that the appearance factor has a great amount to do with the choice of color in the tread and side wall. The black tread with the colored side wall is quite a common choice this year. Another combination is illustrated by the Knight Tire & Rubber Co.'s tire which is made with a white tread and a black side.

United States Tire Business Booming

Between Jan. 1, 1916, and Aug. 15, 1916, as many tires were shipped by the United States Tire Co. as during the whole year 1915, which was a big year. To meet the increased demand, the capacity of the company's plants has been materially increased.

After extended tests, the company is now prepared to produce its new product, the Royal Cord tire in large quantities, and is stocking up its branches. This tire is of the thread cord type, being built up of from four to ten plies of cabled Sea Island cotton, laid into the shape of a tire casing. It is made with a black tread, having a white strip running around the side walls, with the balance of the side walls black. The tread has a continuous ridge at the crown, with transverse corrugations at each side, and is distinctive in appearance.

Four other types are manufactured, with Knobby, Chain, Usco and plain treads. The past year has shown a marked increase in the sale of non-skids and in straight side tires, especially above the 3 and 3½ in. sizes, where the clinchers predominate. The sale of red and gray tubes has shown the same increase as the casing business and the truck tire sales have grown to such an extent that they necessitated an increase in the factory at Providence.

Hand vs. Machine Work

Hand-built and machine-built tires are about equally numerous throughout the list of manufacturers. The New Jersey Car Spring tires are all hand made and so are those made by the Mohawk Rubber Co. The Acme Rubber Mfg. Co. uses hand manufacture exclusively. This concern manufactures only fabric tires. The Standard Tire & Rubber Co. manufactures fabric tires only and uses hand-made production.

The Hawkeye Tire & Rubber Co., Des Moines, Iowa, is parallel with these concerns as its output of fifty fabric casings a day are all made by hand.

The Mansfield Tire & Rubber Co. on this same subject reports 80 per cent of their product made by machine and 20 per cent by hand. This concern has an output of 90 per cent fabric tires and 10 per cent cord. An improvement made by the latter concern, which may be mentioned in passing, is the introduction of the cable base for the straight side tires. The Lancaster Tire & Rubber Co., which produces all fabric and no cord tires, uses only the hand method.

Many Secret Processes

Owing to the important part that chemistry plays in the tire business it is but natural that large numbers of secret processes are being developed. Hence the improvements that are made cannot be explained in detail. One of the sources of improvement, though, is in the efficient arrangement of factories, and the tire companies are learning the lessons of production very rapidly. The Gordon Tire & Rubber Co. has been able to greatly increase its output by a factory rearrangement. This concern manufactures fabric tires, of which 75 per cent are hand made and 25 per cent machine made.

There is no part of the country where tires are manufactured that does not report an increase of business. The Marathon Tire & Rubber Co., Cuyahoga Falls, Ohio, states that its business increased during the year to such an extent that it was necessary to double its working capital. The Mohawk Rubber Co. of Akron has increased during 1916 77 per cent and by the end of the year will probably reach 100 per cent. The Gibson Co. of Indianapolis, Ind., which is the general sales agent for the Falcon Tire & Rubber Co., increased its business 125 per cent. The Alliance Rubber Co. of Alliance, Ohio, increased its output 50 per cent and is trebling its floor space and adding $60,000 worth of machinery.

Best Tread Type Disputed

There is some discussion in tread forms as to whether or not the most desirable is the depressed type or the raised tread. The Mattson Rubber Co., Lodi, N. J., makes a depressed non-skid tread which it prefers because there are no projections subjected to road shocks. This is a wrapped tread, single-cure process tire.

Another concern which favors the depressed tread is the Indiana Rubber & Insulated Wire Co., which has changed so that the raised projections on the tread are now twice the width of the Traction tread, formerly manufactured. The color has been changed to white side walls and brown tread.

Newcomers in the Field

New tire concerns are coming into the business and among the best known of the newcomers is the Brunswick-Balke-Collender Co., Chicago and Muskegon, Mich., which will devote its production entirely to single-cure, wrapped-tread fabric tires. The Gryphon Rubber & Tire Corp., New York, is a new concern which will not be in operation before the first of the year.

Batavia Molded Tread Tires

Batavia is changing from wrapped tread to molded tread manufacture. It is marketing a single non-skid tread, Security, which is 75 per cent of its output. The quantity of the tread stock has been improved and now contains more natural gum. All tires are machine made and the sale of straight sides has shown a great increase. Service stations have been increased and the arrangement of the factory altered to facilitate production. Gray tubes also are made.

Goodyear Makes Millions of Tires

Goodyear is making fabric and cord types and the sale of cords has increased 75 per cent during the year. Outside of the Ford sizes, most of the fabric tires are straight sides. Goodyear advocates somewhat lower inflation pressure than

usual, due to the oversize construction of the casings which thus hold more air. A number of new factory buildings have been put up during the year.

Goodyear has increased its output during the year 78 per cent, and has added about 30 acres of floor space. At present it is producing 16,500 fabric tires a day and 1500 cord tires. The company hopes to have reached a production of 225,000 cord tires by the end of this year and to make 600,000 in 1917. Approximately 70 per cent of the original equipment supplied to car manufacturers have non-skid treads. In 1916 3,500,000 tires will have been turned out and this number is expected to reach 6,000,000 in 1917. In 1915, the total number produced was 2,000,000.

The Dayton company produces both its airless tire in which the air space is taken up by a series of piers of live rubber and a pneumatic type. The airless is largely for fire apparatus. The pneumatic has a very high non-skid tread and the company's faith in its durable qualities is evidenced by a mileage guarantee of 6000.

Swinehart's Big Gain

Swinehart reports a big increase in straight side business, the demand for this type of tire doubling during the year. Total production has increased 30 per cent and this has called for an increase in floor space of 50,000 sq. ft.

Big Four in New Plant

The Big Four Tire Co., has just completed its factory which has 18,000 sq. ft. of floor space and the entire plant will be devoted to the manufacture of Big Four tires. The tire will be constructed entirely by hand at the start though special machinery will be constructed in the course of time. About 100 tires a day will be the capacity after Jan. 1. The big Four tire differs from others in that it is virtually two half clincher tires, there being a clincher rim in the usual place and another clincher rim to which the heavy tread portion is attached. The tire is puncture proof and is made for both passenger vehicles and trucks.

Carsafe Water-Cooled Non-Freezing Brake

SYSTEMS of cooling brakes have usually been found impractical since the cooling extended also the zone of freezing in a most undesirable manner. The liquid around the brake drums is too far away from the radiator, and would freeze in cold weather when the car is left on the street. The Carsafe system is claimed to solve this problem by using a device to transfer the entire water from the brake cooling system to the radiator immediately upon the stoppage of the engine. The piping is therefore empty and hence free from freezing.

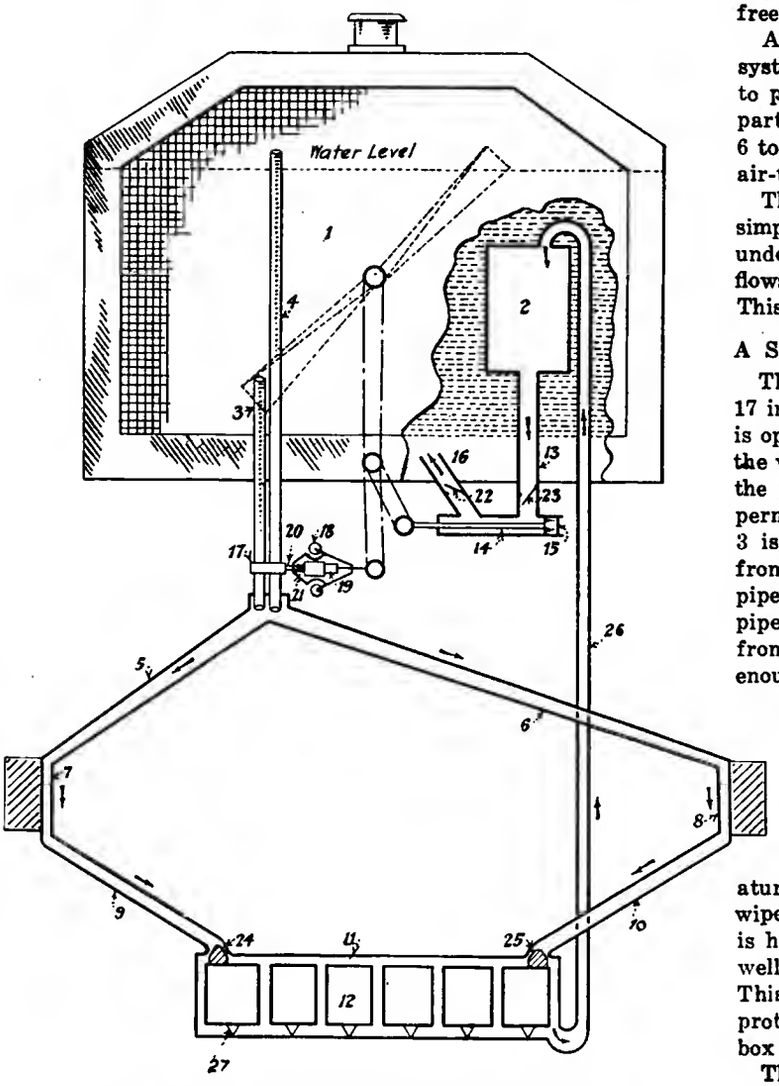

Diagram of Carsafe water-cooled non-freezing brake

As shown in the drawing, the water for the brake cooling system is taken from the radiator. It flows through pipe 3 to pipes 5 and 6, drawn by the suction pump 14, or by the partial vacuum created in the chamber 2 by the pump, from 6 to drum jackets 7 and 8, and then to a shallow water- and air-tight box 11.

Thence the water rises by pipe 26 to chamber 2 which is simply a thin-sheet-metal water- and air-tight box located under the water level of the radiator. From it the water flows to the suction pump 14 which returns it to the radiator. This completes the water circuit.

A Spring Governor

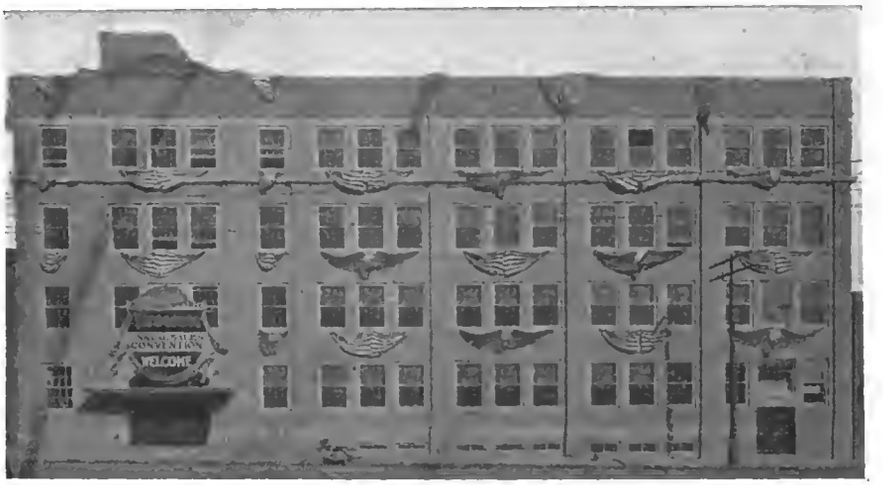
Then there is the spring governor 18 which operates valve 17 in such a manner that when the engine is running, pipe 3 is open, and pipe 4 (which has its upper orifice always above the water, and carries air) is closed. When the engine stops, the pump stops working. At the same time the governor permits the valve to shift to such a position that now pipe 3 is closed, and pipe 4 open. No more water is coming in from the radiator, but there is full atmospheric pressure in pipe 4 and partial vacuum in chamber 2. The pressure in pipe 4 drives the water through the system to box 11, and from there through tube 26 to chamber 2 which must be large enough to hold the entire water used for brake cooling. Hence, in a very little while after the stoppage of the engine there will be no more cooling water in any of the jackets or pipes of the brake cooling system, which is the reason why the latter cannot freeze.

The presence of the described system of brake cooling will not affect very materially the temperature of the radiator water. On one hand there is the heat wiped off the brake drums, which tends to heat it up, which is helped by the fact that the water in chamber 2 is not as well cooled by the fan blast as the rest of the radiator water. This is however largely compensated by the losses from unprotected metal surfaces of the pipes, brake drum jackets and box 11.

The installation of the brake cooling system does not affect the design of the fan, if it has been properly selected.

Tire Makers Active in Welfare Work

Big Producers Realize Benefits Resulting from Mental and Physical Education of Employees —Millions of Dollars for Movement



Firestone Clubhouse erected at a cost of $300,000 for the benefit of employees

AKRON, OHIO, Nov. 17—Recognizing the benefits to be derived from welfare work among employees, all of the Akron tire manufacturers are giving thought, money and time to the subject and in many instances have developed remarkable systems for the protection and uplift of the workers.

There is not one of the companies which are prominent in the manufacture of automobile tires but is providing, not only plenty of light and air and cleanliness throughout every department of its factory to a degree unimaginable only a few years ago, but also extends to the workers every advantage of equipment to raise their general physical and moral welfare and to increase the feeling of ease about the present and of happiness for both present and future, which have been found so closely allied to efficient execution of work of all kinds on the part of the employees. These features of factory welfare development include departments for reading, physical culture, modern eating facilities and means whereby the employees receive a reasonable maximum of insurance in case of illness or injury.

Firestone's Clubhouse

The Firestone Tire & Rubber Co. during this past year has erected a clubhouse consisting of four stories and a basement, 151 by 125 ft., constructed of brick, steel and glass to correspond with the various factories belonging to the company. The basement contains a swimming pool 60 by 20 ft., which holds 62,000 gal. of water. The water is passed through two charcoal filters, one alum filter and two violet ray sterilizers to insure purity. There are fourteen shower baths in connection. The basement also includes a barber shop with four chairs, and eight bowling alleys constructed in the latest and most improved style.

The first floor has a restaurant for factory employees, with a seating capacity for more than 600.

The second floor is furnished with a restaurant for office employees. It seats more than 700 at a time and has a modern kitchen equipment. All bread and pastries are baked here and are thus insured cleanliness and purity.

The third floor contains a reading room and an auditorium with a complete stage effect. Two moving-picture machines have been provided and the company gives educational and entertaining exhibits for the workers. The auditorium is so arranged that the sides may be converted into convention rooms, if desired, and these are sometimes used for conventions or dances.

The fourth floor consists of the club rooms, and contains a library and reading room in combination, and also a girls' rest room, where employees may come between working hours to rest and read.

A $1,000,000 Fund

The Firestone company has financed the clubhouse in its construction and equipment, amounting to $300,000, and intends, through a $2 fee for male employees, a $1 fee for females, and a $1 fee for non-resident members, to make the institution self-sustaining. The company has also entered into other welfare work, including a dental and medical department, and has recently voted a $1,000,000 fund for employees' welfare and insurance, besides arranging a plan to provide employees with homes at cost on a small weekly and monthly payment basis. The homes are erected on a plot known as Firestone Park, and workers are invited to occupy them without making any large deposit in advance.

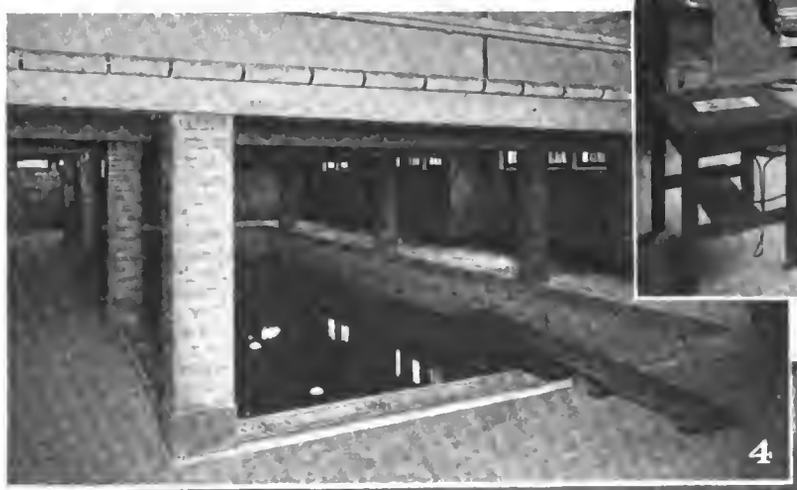
Goodrich Welfare Work

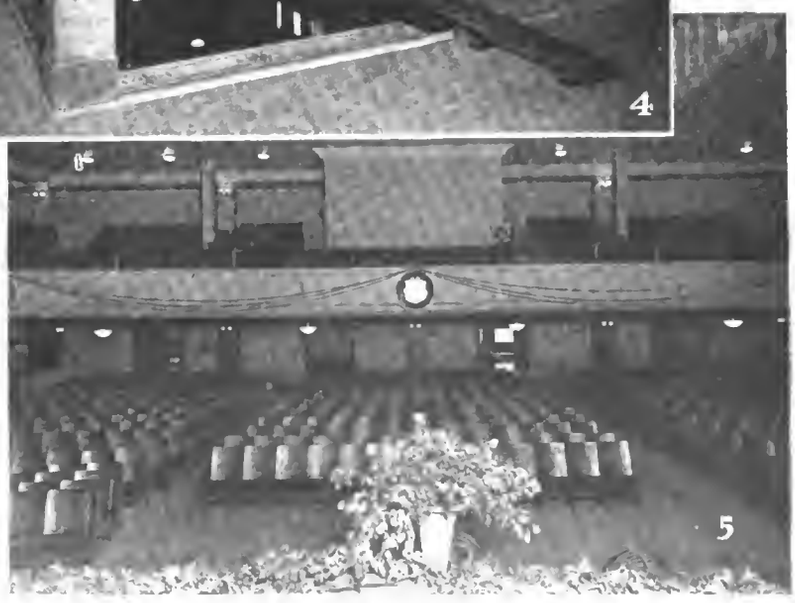
The B. F. Goodrich Co. provides social insurance, medical supervision and healthful recreation for its employees through its Department of Industrial Relations, which includes divisions of labor, health and safety. The company goes beyond the State law requirements in granting compensation to those injured in its plant and maintains health insurance providing compensation for employees detained from work more than 7 days through illness or injury occurring outside the plant. This compensation is paid from the first day of disability for a period not exceeding 1 year. Married men, single men with dependents and all women receive two-thirds of their wages, and single men without dependents one-half their wages. Other welfare features include a special maternity benefit to married women who comply with the regulations of the health department, a life insurance plan which gives employees $500 insurance, increasing to a maximum of $1,000 during the first 5 years of employ and various service annuities are paid with a minimum of $20 and a maximum of $100 per month. Employees are given a physical test when entering employment and upon return after illness. Dispensaries, medical clinics and clinics for special diseases are maintained. A corps of visiting nurses is employed.

Goodyear Factory School

The Goodyear Tire & Rubber Co. has established a factory school, which is attended by 500 students, in which common

Glimpses in the $300,000 Firestone Clubhouse





1—A corner of the dining room in the Firestone clubhouse for the use of office employees of the Firestone Tire & Rubber Co., Akron, Ohio

2—Part of the dining room provided for the use of factory employees of company. Note the clean and substantial character of the appointments

3—The barber shop of the clubhouse is fitted with up-to-date equipment and is kept scrupulously clean. Illumination is aided by the skylight forming the ceiling

4—The swimming pool contains 62,000 gal. of water, which is filtered daily. There are fourteen shower baths in connection with it which must be used before entering the pool

5—Auditorium of the Firestone clubhouse which is laid out with convention rooms around the walls. The seats are frequently removed and the space used as a dance hall

school lessons, factory work and technical studies are taught. The company has an athletic director, whose sole duties consist of providing athletic diversions for employees. An insurance plan similar to the Goodrich system is in operation, and a hospital with a factory doctor has been installed. Old age pensions are given. Playgrounds have been provided for children of Goodyear employees and the company has purchased land and erected homes, which the workers may purchase by small instalments at practically cost price. A safety first propaganda was started in the factory during the past year, which has reduced accidents almost 100 per cent.

Miller Has Adjustment Board

The Miller Rubber Co. has embodied a sort of adjustment board among the employees of the employment department and allows them to make minor adjustments of difficulties arising among workers. One American and one foreigner, who is an excellent linguist, talk to all employees and to all who apply for work. A hospital has recently been installed and equipped with every necessary facility, and has a trained nurse at its head, who makes visitations constantly to the homes of any employees who are sick or injured. The nurse and one forelady also act as a sort of clearing house for the troubles of girl employees. The company fosters all sports and purchases all essential equipment for indoor baseball, basketball, football and other games, and has provided a field at Kenmore for the use of the workers. Study clubs are now in process of organization, and a library has been started.

The study clubs include ten courses, consisting of the following: Production problems; office methods; personal efficiency; marketing problems; fundamentals of economics; accident prevention; business law; real estate, insurance and investment; elementary accounting; business English. It is planned to have small groups of eight or ten people take one course at a time, and if more than that number apply, a second group will be started. Classes will be held in the evenings from 5 p. m. to 7 p. m., and supper will be served by the labor department at actual cost.

The company has also instituted a suggestion system allowing any employee to make suggestions and submit them to the administrative offices. Slips of paper and envelopes are provided and boxes are hung from many walls in which the suggestions may be dropped. They are gathered daily and passed upon by a committee of five, appointed by the general manager. Each suggestion taken up and acted upon is paid for with a substantial sum. During the first month of the suggestion plan eighty-six suggestions were received, of which eighteen were considered worthy of adoption, and the employees entitled to reward received from $1 to $5. Such recommendations were turned in as a liner improvement, an increased record efficiency, and an improved method for handling scrap. The company issues a booklet monthly giving the authors of suggestions that won rewards.

Megow Attachment Converts Car Into Tractor

WE have become very familiar with attachments for transforming a Ford touring car into a commercial vehicle. The latest, however, is a device which makes this car a tractor. The accompanying illustrations show the device in action ploughing or breaking a timothy and clover field with two 14-in. stubble plows. The advantage claimed for this device is particularly in regard to the power, which is applied at the driving wheels.

Car, Tractor or Truck

With this device, the inventor, who is Edward J. Megow of Minneapolis, Minn., states that one can use the Ford or other make of car, to which the device is applied for ordinary purposes. He states that in 30 min. the automobile can be transformed into a farm tractor capable of pulling the two 14-in. plows. In another 10 min. a set of truck wheels can be slipped in place and the outfit can be used as a road tractor or truck capable of pulling a great weight. The attachment will probably sell for about $200.

One of the advantageous features of the invention is that all the gears are inclosed and run in oil, being thus protected from dust and dirt and rendering it possible to leave the machine out in all kinds of weather.

Drive Stresses Taken by Wheels

A spindle is attached at the rear, thus furnishing an extra bearing and relieving the axle bearing of any strain. In the driving drum it will be noted on the side of the wheel where the gears are carried the power is applied at two points opposite one another on the periphery, thus dividing the stresses and eliminating the use of special bearings to take care of undue loads. As the point of power application is several inches from the center of the wheel, good turning torque is secured. All the working stresses are taken by the tractor wheels and none by the frame structure. The only change in the power plant of the car is that it is necessary to install a circulating pump and to increase the speed of the fan. With the device the gear reduction can be altered within wide limits, thus rendering it possible to take care of widely varying conditions.

Left—Megow tractor attachment on a Ford roadster and drawing two 14-in. stubble plows. Note deep furrows and also plowed area to the right of the machine. At the right the same vehicle, in side view, gives an idea of the type of wheels used for tractor purposes

Republic Rubber Co. Protects Workers

Safety Placards Throughout Factory Buildings and Yards, Railings and Guards on Machinery Some Measures Adopted

Safety First display window situated near the main entrance to the plant of the Republic Rubber Co., where all matter pertaining to safety and welfare is displayed for attention of workers

SAFETY FIRST, that slogan of accident prevention originating in the fertile mind of a minor railroad employee several years ago, has worked itself into our national life to an extent that no other slogan has. Not even the old C. Q. D. or the more modern S. O. S. of a ship in distress at sea is so well known as these two warning words first adopted by the railroads. This slogan and the spirit back of it next became one of the principal considerations of factory management. The plant of the Republic Rubber Co., at Youngstown, Ohio, is not considered a dangerous place to work, but, as in any other establishment employing a large number of men and using various types of intricate machines, the carelessness of a few is a threat to the welfare of many.

In order to safeguard its employees from accidents which, although not actually always impending, might occur at any time, the Republic company has placed upon its staff George Hodgson, whose duty it is to sleuth about the 17 acres of floorspace of the factory with an eye ever watchful to the prevention of possible accidents with resultant injury to the men who make the tires.

The factory managers for the Republic company must have had in mind that old adage about locking the barn after the horse was stolen when they planned this policy. For it is usually too often the case that a machine is fitted with an accident preventing screen or other device after that machine has killed its man. The reverse is true in the Republic plant where the whole policy is to prevent even the first accident.

A policy of accident prevention in a manufacturing establishment has as its end the safeguarding of mechanical working parts by protective devices suited to the particular requirements. The beginning of a campaign for the prevention of accidents must appeal to the human element. Education is the first requisite of such a campaign. Without education for carefulness the policy can work to but 50 per cent of its efficiency. Money invested in protective devices will not realize the fullest possible results without education.

Republic Rubber Co. officials recognized this truth in plotting its policy for the elimination of preventable accidents. Consequently, the first step taken was an educational one. The entire factory was placarded throughout with Safety First signs and warnings designed to make the employee think first of his own welfare and of the welfare of those about him. Above the main entrance to the factory hangs a great Safety First sign. This sign, placed as it is, gives the employee the keynote of his whole day's labor as he enters the factory in the morning. In addition to being impressed by these warning words as he enters the factory for the first time, the new employee is given a little booklet as soon as he is hired. This booklet contains the factory rules and emphasizes the fact that he is always to guard himself and his fellow workmen.

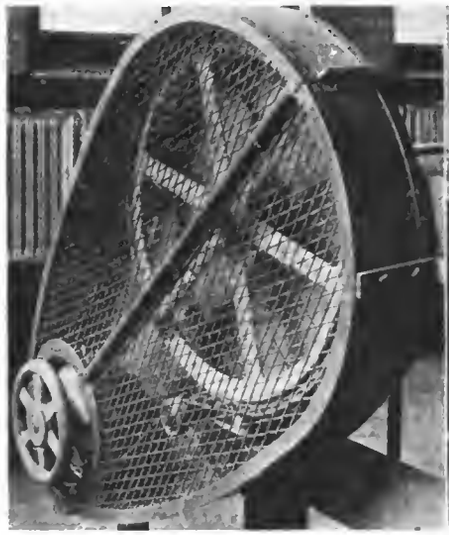
On this page appear a few of the signs and warnings which have been posted about the factory in furtherance of the educational side of the campaign. On the opposite page are shown some of the devices which inclose machinery that might otherwise be dangerous when carelessness played its part.

Another simple guard is the balcony rail guard made out of expanded metal. This guard is used all around the balcony on the second floor of the machine shop. Ordinarily this space would be open and hammers or other articles might fall through it to the injury of workmen below.

Some of the signs which are used about the factory buildings, yards, etc., of the Republic Rubber Co. plant

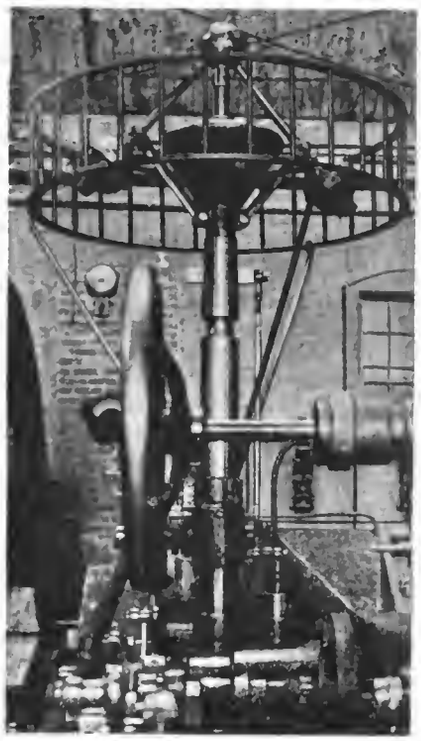
Safeguarding Devices Used for Protection of Workers in Republic Rubber Factory

A safety sign mounted at one of the entrances to the factory of the Republic Rubber Co. It is electrically lighted at night

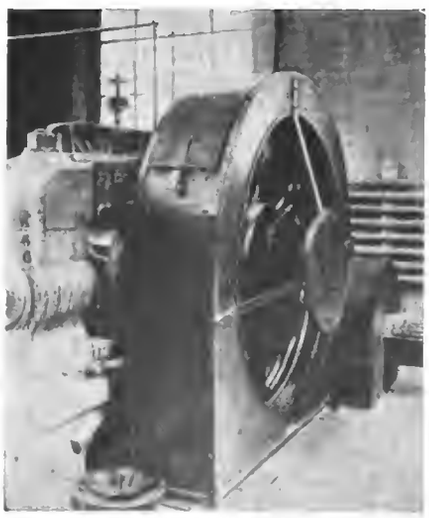


Above is illustrated the type of expanded metal and sheet iron guard employed in the Republic factory for sprocket and chain drives of the sort illustrated

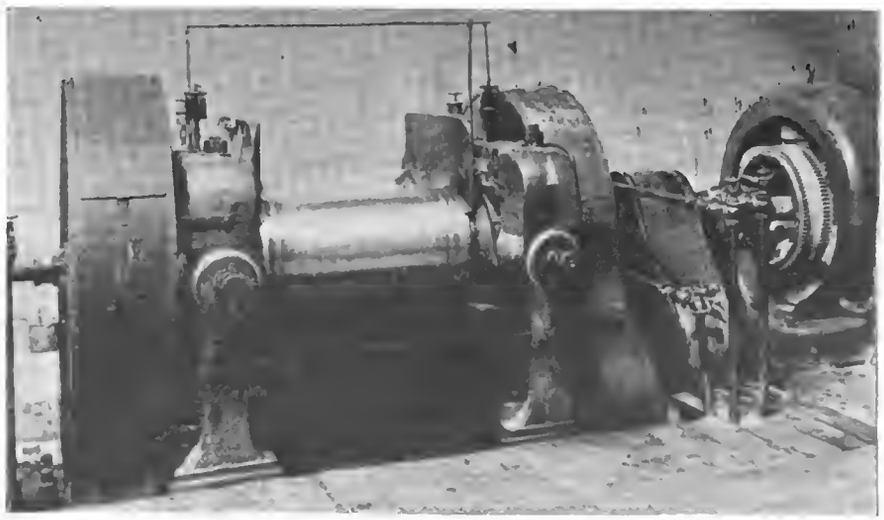
Another expanded metal and sheet iron guard for covering motors, starting boxes and switches, making it impossible for either workers or material to touch them



While not ordinarily dangerous, a fly-ball engine governor has latent possibilities, and it was considered wise to install the guard illustrated above



Guard used on rubber mills in calender room. Note the covered keyhead and hinged opening in front of guard for greasing and inspecting the gears



The rubber refining mill illustrated above is an excellent example of the thorough way in which the machinery of the Republic company is safeguarded. All gears are entirely inclosed and each mill is fitted with an electric safety stop over the rolls, which instantly stops the machinery of the mill in case of an accident

The Determination of Headlight Glare

Present Chaotic Condition of Legislation Throughout Country Largely Due to Lack of Definition of Glare, J. B. Replogle Tells Detroit Section of S. A. E.—Rules in Various Cities

DETROIT, MICH., Nov. 16—When an automobile headlight is so powerful as to be dangerous in its blinding effect it is a glare.

Glare cannot be regulated either by a bulb or a reflector but must be determined by reaching a certain unit standard of light beyond that which is considered glare, this unit to be discovered by the effect on the vision of an approaching driver.

These were the principal details on the subject of glare discussed by J. B. Replogle, director of research of the Remy Electric Co., before members of the Detroit section of the Society of Automobile Engineers last night.

What Constitutes Glare?

In his address Mr. Replogle confined himself entirely to the question of what constitutes glare and how it can be measured, thus precluding any discussion as to the merits of the various methods of eliminating glare. He told of his investigation of the ordinances of the different cities and States and read a number of them showing how futile and in many instances ridiculous all attempts have been in the effort to define or regulate glare.

"When I got through with this mass of correspondence," said Mr. Replogle, "I found myself in about as puzzled a condition as I was at the beginning. The only reference made to a unit was where the candlepower of the bulb was specified. Inasmuch as it is a matter of common knowledge that the effect produced by a lamp of a definite candlepower varies many hundred per cent according to the way it is reflected or condensed, the candlepower unit is a meaningless one.

"The glaring effect of a headlight is to a very great extent a function of its environment. For instance, in broad daylight the brightest headlight does not cause inconvenience, while on a very dark night on a country road a headlight which is ordinarily considered to be well dimmed often produces extreme discomfort and constitutes a real menace. Suppose you are looking in subdued light at an object which is sufficiently illuminated to be plainly visible. The pupil is dilated so that the eye can receive as much light as possible from the object to be viewed. If now a bright light is thrown in your eye, the pupil contracts so that while the same amount of light is coming from the viewed object as before, but a small portion of it can reach the retina of the eye and produce vision. This reduction of vision the ophthalmologist calls 'depression in vision function.'

Glare Quantitatively Defined

"A qualitative definition of glare is that it is depression in visual function due to contrast between the direct illumination of the eye from a source of illumination and the illumination of an object it is desired to view. This glare is prohibitive when the object of vision is difficult to discern. Accepting this as a working hypothesis, we next approach the question as to a unit of glare and how to measure it.

"In technical photometry, a source of illumination is known by four characteristics. 1. Its luminous intensity or the rate at which it is emitting light in a given direction: its unit is the candlepower. 2. Luminous flux or the total amount of light emitted in unit time: its unit is the mean of the spherical candlepower. 3. Illumination or the illuminating effect produced at a given distance: the unit is expressed in candle feet or foot candles. 4. Intrinsic brilliancy which is expressed in mean spherical candlepower produced by the source in question and an arbitrarily selected standard.

"The candlepower or the unit of luminous intensity has been defined as the light produced by a standard sperm candle which consumes speraceti at the rate of 120 grains per hour and the candlepower of the source under consideration is measured by placing a screen between a standard source such as a standard candle and the source under investigation and adjusting its relative distance from each until it is equally illumined by each.

"Luminous flux is measured by placing the source of illumination within a dead white sphere and comparing the illumination produced on the interior surface of the sphere by that of a standard source.

"Intrinsic brilliancy is obtained by dividing the luminous flux by the superficial area of the source of light. The unit of illumination, the foot candle, is defined as the illumination produced by a standard candle at a distance of 1 ft. from the object.

"Let us see if the unit of headlight glare cannot be successfully adapted from the standpoint of the unit of illumination, or the foot candle. It is wise to establish our units so as to apply to the most perilous situations with the feeling that the other situations will be thereby satisfactorily taken care of."

A Psychological Peril

Here, Mr. Replogle pointed out that there is a psychological peril when animate intelligence is confronted by a powerful swift-moving machine and that bright lights tend to increase the danger and stated that if conditions are so arranged that it will be safe for the animate intelligence, horse or man, provided it retains its self-control, that that is all that can reasonably be expected. In short, any headlight that causes a dangerous situation, even though the animate intelligence retains its self-control, is a glare.

The thing most interesting to the approaching driver, stated Mr. Replogle, is the ability to see the road and to avoid the ditch, and to do this there must be a minimum relation between the light shining in his face and eyes from the approaching headlights and the illumination on the roadway.

Pointing out that it is a superstition to believe that a driver can overcome the dazzling effect of an approaching car by turning on his own lights, Mr. Replogle applied this detail to the problem of glare by an example, using two principal points: A—the roadway which the approaching driver endeavors to see in order to steer correctly; B—the eyes of the approaching driver. Placing point A 5 ft. to the left of the fenders of the car carrying the headlights and about 4 ft. in front of it as the point on the roadway which the driver is trying to see, and placing point B, the eyes of the driver approaching, not less than 3 ft. from the ground and between 25 and 50 ft. from the headlight, he showed that the eyes at point B will be dazzled by the glare if the light striking

them is much greater than the light from the headlight that strikes point A. Experiments, he stated had proven that when the illumination at point B is more than 4½ times that at point A, the light constitutes a menace and should be termed glare.

To prove these remarks, Mr. Replogle used a headlight, a 15-candlepower light and a piece of steel ending in a circle and attached to a rheostat, asking several members present to peer through the circle at the object before and below the headlight until they could distinctly distinguish it. The light was made more and less powerful until found correct. Later in the evening these tests were checked and found to correspond to previous ones that produced the estimate of 4½. Mr. Replogle also introduced an instrument he has devised and which he calls a glaremeter, a device which may be used in conjunction with his estimates to discover glare.

Several Brief Discussions

Others followed the address by short discussions. Dr. Louis Bell, of Boston, associate of Thomas A. Edison in the Edison laboratories, objected to the distance of 25 ft. specified by Mr. Replogle, and pointed out that when two automobiles operating at 30 m.p.h. are close to one another they must pass at a speed of 88 ft. a second, which would not allow sufficient time if the drivers had to wait until they were so close to determine their movements. E. C. Patterson, president of the Warner-Lenz Co. of Chicago, made a short address, telling of the numerous communications his concern receives constantly that inquire for means of eliminating glare. E. F. Wackwitz, of Gray & Davis, Inc., objected to Mr. Replogle's ideas and stated his belief in the ability to regulate glare by regulation of filaments and reflectors, and said that insufficient light caused more harm than glare. W. E. McKechnie, of the Cadillac Motor Car Co., and chairman of the committee on headlight glare, gave a brief description of the work of the committee and declined to announce results of tests pending their completion. J. Caldwell, of the National Lamp Works, recommended parabolic lamps arranged with high and low-power bulbs for city and country driving. He also stated that various experiments made by his company led them to believe that most devices that cut the intensity of beam tend to limit the view of action and that the best plan would be to eliminate the light from the upper angles by tilting it downward to an angle one-half of the angle equal to the spread of the beam.

Mr. Replogle in a short summary answered the various criticisms, stating "Glare as I used it is only jargon and not at all scientific and I mean by glare merely the headlight proposition we discussed here to-night. If 25 ft. is safe it is also safe when the distance is 200 ft. Contrary to Mr. Wackwitz, I believe that it is glare and not insufficient light that causes the hazard. Decrease the light in the eyes of an approaching man or increase the light on the road and you eliminate the danger."

Over 400 in Attendance

More than 400 people attended the meeting, including members and guests. Among those present were Joseph Bijur of the Bijur Motor Lighting Co., Hoboken, N. J., Alden L. McMurty, consulting engineer, of New York, R. H. Wells of the Badger Brass Co., Kenosha, Wis., and K. W. Zimmerschied of the General Motors Co.

To secure data on the ways in which the various cities are dealing with the glare problem Mr. Replogle sent letters to fifty-eight cities. Ordinances were received from twenty-three cities, sixteen of which follow:

Boise—Blinding or searchlights prohibited.

Buffalo—Dazzling or blinding light—or a lamp or light exceeding 20 candlepower with or without reflector—prohibited.

Cheyenne—Should not give forth a blinding glare, but should shed a rather subdued light.

Chicago—Unlawful to use acetylene, electric or other bright headlight or any headlight the rays of which shall be intensified by any parabolic or condensing reflector, unless such headlight shall be properly shaded so as not to blind, dazzle or confuse other users of the highway or make it difficult or unsafe for them to ride, drive or walk thereon: Inspection Board provided.

Cincinnati—Similar to Chicago, but shading or dimming upon half of lens is deemed compliance.

Cleveland—A lighting device is prohibited which concentrates and projects any part of the light into a beam, unless the said lighting device is so adjusted that at a point, a distance of 75 ft. or more in front of the vehicle, no part of the reflected beams of light shall be visible more than 3 ft. above the surface of the roadway.

Denver—Same as Chicago.

Grand Rapids—Same as Chicago, with the addition that the use of amber glass (so-called) as a screen shall be deemed a compliance when effective.

Louisville—Dazzling or glaring headlights prohibited.

Milwaukee—Lamps prohibited which project main light rays above a plane which shall strike the roadway more than 200 ft. forward from base of vehicle on a horizontal roadway.

Omaha—Headlights must be so focused and directed that the uppermost rays shall not be elevated more than 6 ft. above the surface of a level roadway at a point 100 feet ahead of the lamps. Must be dimmed by being suitably shaded or covered that there shall not be a glaring or dazzling effect therefrom.

Portland, Ore.—Headlight shall be so controlled that it will not blind, dazzle or confuse other users of the streets or make it difficult or unsafe for them to ride, drive or walk thereon.

San Francisco—Must be so dimmed or covered that the glaring effect of headlights shall be done away with.

Salt Lake City—Light prohibited of such power or strength as to dazzle pedestrians or drivers of vehicles moving in opposite directions.

Toledo—Same as Chicago.

Baltimore's Elaborate Provisions

"The city of Baltimore has gone into the matter very much more thoroughly than any other city from which we received returns and I shall read their ordinance almost in its entirety as being representative of the most painstaking attempt to cover the situation," said Mr. Replogle.

Definitions—The term "headlight" shall be taken to embrace any lighting device designed to display a light on a motor vehicle in the direction in which said motor vehicle is designed to proceed, the term including what are commonly denominated as "side lights" when the same are fitted with reflectors and equipped with electric bulbs or other means of illumination of more than 4 candlepower.

Maximum Standards—No motor vehicle in use in Baltimore City (including motorcycles) shall be equipped with any electric bulb or other lighting device of a greater rated capacity than 30 candlepower, no matter how the same may be shaded, covered or obscured.

No "side light" shall be equipped with any electric bulb or other lighting device of a greater rated capacity than 4 candlepower unless shaded, covered or obscured as hereinafter provided.

Operation and Control—No motor vehicle, including motorcycle, shall be operated within the limits of Baltimore City equipped with any device by which the headlights can be switched or cut off or on, covered, shaded, deflected, dimmed or lowered from the seat, unless the headlight itself is equipped with some means of preventing glare which has been

approved by this Board. In short, the ordinary "dimmer" or auxiliary light operated by a switch from the seat will not be permitted unless the headlight so operated is itself so shaded or constructed that, even when cut in from the seat, it will not produce glare.

Oil Lamps—Unless an oil lamp of exceptional brilliancy be used, no device to prevent dazzle or glare will be required. Where, however, oil lamps of great brilliancy are used, some anti-glare device as hereinafter prescribed shall be used with the same.

Gas Lamps—All gas headlights (or sidelights of over 4 candlepower) shall be equipped with some anti-glare device as hereinafter prescribed, this provision to apply to motorcycles as well as all other motor vehicles.

Electric Lamps—All electric headlights (or sidelights of over 4 candlepower) shall be equipped with some anti-glare device as hereinafter prescribed, this provision to apply to motorcycles as well as all other motor vehicles.

Anti-Glare Devices—The use of any headlight of not over 30 candlepower shall be lawful where the glass in front of the same shall have been covered or coated with tissue paper, paint, frosting or any other substance or material of sufficient opacity to prevent the outlines of the flame or electric light being visible when looking through the glass from the front. If desired, a circular space not over two inches in diameter may be left clear in the center of the front glass or a space not over 25 per cent of the entire area below the level of the bottom of the flame or bulb. If these latter options come to be abused by motorists to such an extent as to defeat the purpose of the ordinance under which these rules are adopted, this portion of this rule permitting any portion of the front glass to be clear will be revoked by the Board without notice.

(Where the use of non-blinding devices of any kind cut down the light too much the new nitrogen electric bulb recently put on the market will be found to give additional light even when of the same candlepower as the ordinary bulb.)

Acting under the authority conferred by Section 5 of Ordinance No. 630, approved May 27, 1915, the Board of Motor Vehicle Headlight Inspection has heretofore approved, and will from time to time hereafter approve certain special devices designed for the prevention of glare. Motorists are authorized to use any such device, and upon purchasing the same are given a certificate from the dealer to the effect that the same has been duly approved by this Board. The ordinance provides in effect that said certificate when displayed to any police officer will render the motorists immune from arrest under said ordinance.

Proper Adjustment Necessary

No certificate issued by the Board as to any special anti-glare or non-blinding device is effective, according to its terms, unless such device is properly adjusted as directed by the maker. Motorists should therefore be careful in the first instance to see that such devices are properly adjusted, and, in the case of those apt to get out of adjustment, thereafter to see that they remain in proper adjustment. Most of the devices approved by the Board are not susceptible of improper adjustments, and such type of device is preferable.

In view of the dangers attending driving at night without adequate light, the Board does not approve the extinguishment of headlights outright. The devices above described all yield sufficient light to make night driving safe, but at the same time overcome the dangers attendant upon the use of glaring headlights.

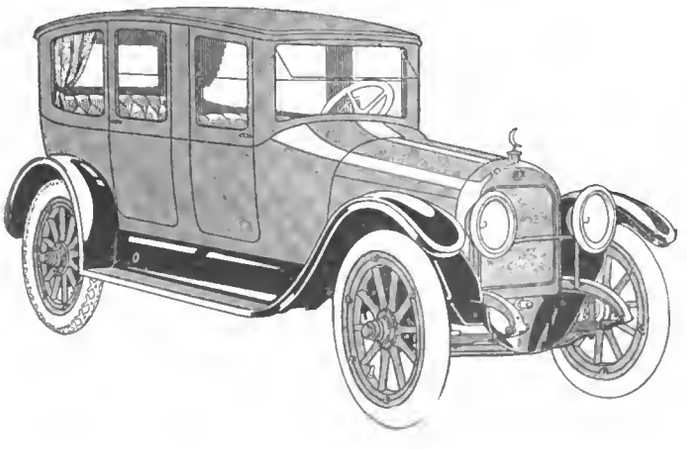
Moon Coupé and Convertible Sedan

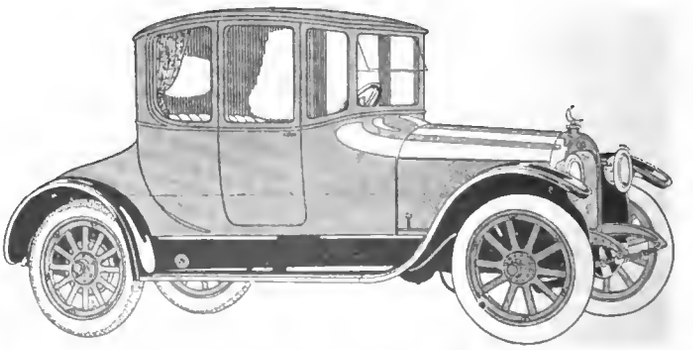
THE Moon Motor Car Co., St. Louis, Mo., has included a four-passenger coupé and a convertible sedan in its line of closed cars for the coming season. These are illustrated herewith. In the coupé the three-passenger main seat is staggered and set back from the driver's seat, which has a glove box behind it. There is an auxiliary folding seat in the right front corner for the fourth passenger. Plate glass windows without sash and fitted with anti-rattlers are used, all dropping in metal channels lined with felt. A split type ventilating adjustable windshield is employed and there is an electric dome lamp. The coupé is fitted only to the 6-66 chassis, this model selling for $2,150.

The convertible sedan is a five-passenger type, the top being of aluminoid steel and upholstery similar to that for the coupé. This model is made for the 6-43 chassis, selling for $1,450. It has a dome light in the center of the top and an integral limousine windshield.

The other closed models which the Moon company is furnishing for the coming season consist of four-passenger cabriolet types, seating three abreast and one on a folding drop seat, and selling for $1,850 on the 6-43 chassis and for $2,150 on the 6-66; and a seven-passenger sedan with a large door at each side and a slanting windshield. This sedan is fitted to the 6-66 chassis and lists at $2,250. It is a Springfield metal body type with pillar partitions between the windows.

Upholstery on all models is in black or Spanish leather with dark blue or green broadcloth above the belt line, although either broadcloth or whipcord may be used throughout.





Above is illustrated the Moon convertible sedan top mounted on a Moon chassis. This top is easily and quickly removed At the left is the new Moon four-passenger coupe. The sashless door windows of heavy French plate glass drop and are fitted with patented window lifts. There is a dome light in the center of the top and the windshield is made in three pieces

Successful Business and the Trade Press

Industrial Changes in This Country and in Europe of Greatest Importance to Our Business Interests Best Brought Out and Discussed in the Trade Journals

By Edward N. Hurley
Chairman Federal Trade Commission

¶ EDITOR'S NOTE:—*This article consists of extracts from the address delivered by Mr. Hurley on the subject before the recent meeting of the Associated Business Papers in New York.*

UNDER present industrial conditions both in this country and in Europe it is especially desirable, and in fact, actually necessary that we keep in touch with the changes and developments taking place throughout the world. With this idea in mind, Edward N. Hurley, chairman of the Federal Trade Commission, has been keeping in close touch with the business papers and the following observations are based on his experience with these publications as indexes to the world of successful business.

Industrial Changes in Europe

When we think of Europe we think of a continent engulfed in war, devastated and disordered, but I want to say to you gentlemen, that we must correct that conception. While in many respects we know little of what is going on in the warring nations, we do know that within sound of the guns, almost within reach of the falling shells, Europe is reorganizing her industries. Under the stress of a life and death struggle every effort is being made to obtain the highest efficiency in the production, the distribution and the use of commodities of all kinds. Conservatism in industrial ideals and methods has been blasted and shattered to pieces in the shock of war, old systems that normally would have hung on for years have been discarded in a day; old equipment that would have been retained for years has been scrapped as fast as possible for new installations of the most advanced types. New processes are being discovered, new inventions are being made, and new forms of organization are being created. Let me illustrate. Industrially, France has been preeminently the land of small-scale, highly individualized production, but she now lacks human hands. In France, little farms that for generations have been farmed practically by hand or with the aid of a horse or two, are being thrown together and farmed cooperatively by tractors, gangplows and modern agricultural implements. France must rely on machinery. Her business men are studying and are applying American systems of manufacture in factory construction, in equipment, and in large-scale, highly systematized production.

England industrially has been preeminently the land of yesterday. Conservatism was the dominant characteristic of British business. While Massachusetts was making textiles with automatic looms under conditions that permitted one operator to tend from sixteen to twenty-four machines, Lancashire clung to old equipment and conditions under which one operator could tend but four machines. But at last England is aroused, and to-day American books on efficiency and scientific management are being bought by the hundred and studied all over England. The war has compelled Great Britain to make 30 years of industrial progress in 30 months.

Before the war Germany was probably the most highly organized and efficient manufacturing nation in the world, but in Germany organization and efficiency have been still further developed and, no matter whether victorious or defeated, the Germany that emerges from the war will be years ahead of the Germany we knew in 1914.

We Must Keep Step

These changes are of great concern to us. We may not realize this to-day, because things are coming our way now, but we must look ahead to the future conditions we must prepare to meet. Within 5 years we shall find a new Europe competing against us, with war-sharpened brains and war-hardened muscles, not only in our foreign markets but also right here at home. If our industries are not to be caught slow of mind and flabby of muscle we must improve our business organization, must increase our manufacturing and merchandising efficiency and must keep pace with every step in Europe's industrial progress.

Individuality Plus Efficiency

It is my belief that if the smaller merchant and manufacturer who has no adequate cost accounting system will practice the fundamentals of business and will take the first step toward improving his present methods, he is bound to succeed, and it will be possible for him to succeed on a scale that will mean expansion and development. If he does adopt sound business methods it will be easy for him to compete with the large merchandising and manufacturing firms of the country, as individuality plus efficiency will take care of itself under any and all conditions.

Banker Helping Sound Business

The man who does not know his true costs is the man who prices his goods foolishly, and thereby impairs the business of his sound competitors at the same time that he ruins his own. Too low price making, based on guesswork or on partial costs, is a menace to sound business. Please understand me, the menace is not in underselling, for a business concern must expect to face the low prices that are due to efficiency. But even the most efficient concern is not always able to meet cut-throat prices based on ignorance.

It is time for the business men of this country to get their house in order if they desire to improve their standing at their banks. I predict that within 5 years there will be very little money loaned by any banker in the United States, to any merchant or manufacturer who does not present a statement showing detailed information, not only regarding his true assets and liabilities, but also indicating that he is conducting his business in an efficient manner and that he knows his true costs.

Trade Associations

Much can be accomplished through trade associations.

The trade association has a wide field of useful and proper activities. Concerns in the same industry may take common action looking toward improving their processes of manufacture, standardizing their products, improving their systems of ascertaining costs, and obtaining credit information. The

welfare of employees is one of the important matters which can be best developed by cooperating in associations. The smaller manufacturer who has not the laboratories and the experts to work out his many problems by himself is especially benefited by being a member of these trade organizations. The present tendency of the larger firms to think of the smaller man in the proper spirit and to assist him in arriving at some practical method of meeting his many problems—in short, to live and let live—is to be particularly commended.

Price-Fixing Bogey

An underlying fear lingers in the minds of some people that trade associations, if allowed to exist at all, will go too far. They assume that where competitors are allowed to meet and discuss the main facts of their business, they will inevitably discuss, perhaps in secret, those activities which are illegal. It is true that there have been associations which have violated the law and attempted to fix prices. The great majority of our associations, however, have undoubtedly been occupied in necessary and proper work.

Suppose that there are 500 trade associations organized for the purpose of improving the conditions of their industry, such as standardizing their products, improving their cost accounting methods, and discussing their common problems. Suppose that ten of them take advantage of this opportunity and fix prices, which of course is illegal. Is there any reason why the Government should condemn for this reason the 490 who are endeavoring to work out their managerial problems in such a way as to bring benefits to their business and to the country as a whole? It was once the policy of the Government to devote most of its efforts to opposing and ferreting out the methods of the ten and to neglect or condemn, without a hearing, the 490. The Federal Trade Commission is opposed to the ten who are violating the law and will start proceedings against them if their acts fall within its jurisdiction; but it feels that its attention should be given especially to the 490 and that it should assist and co-operate with them in improving their business.

I am heartily in favor of competitors meeting in trade associations when they meet for the purpose of improving their cost accounting methods, discussing better systems of standardizing their products and materials, and working out more efficient methods of producing their products at the lowest possible cost, or any other questions that go to develop efficiency.

When trade associations meet for these purposes every member profits by it; every stockholder and employee is benefited. It is also helpful to our country as a whole. The Government should encourage and assist the development of trade associations of this kind.

The Broad View of Business

It is my belief that the business men of the country in trade associations are going to profit materially by coming in contact with each other, but I realize that possibly some associations through ignorance or design may take advantage and do things directly or indirectly that violate the law. I am not in sympathy with the class which knowingly resorts to these methods, and it is my hope that cases of this kind will be few and far between. Organizations of this kind which violate the law are doing a great injustice to the honest trade associations and business men of this country.

We cannot develop efficient methods of manufacturing and improve the conditions in our respective industries, which are needed so badly, if, when we meet in trade associations, our thoughts are not on improving our manufacturing methods and ascertaining our true costs, but on the question of fixing prices.

One of the great needs among American business men to-day is a broad view of business in general and a comprehensive grasp of the needs of industry as a whole. Too many American manufacturers and merchants center all their energy and attention upon their particular establishment and the work of making profits for it. Men at the head of factories need the point of view of what might be termed the statesmanship of business. They need to appreciate the fact that their plant is a part of a great industry; that their individual welfare depends very largely upon the welfare and progress of the industry as a whole, and of industry in general. Whatever promotes the welfare of other concerns in industry and the welfare of that broad group of people which we call the public is bound to react favorably on individual concerns.

Government and Business

Government and business, more than anything else, need, as it were, to sit down together and consider the problem of our business and industrial welfare, not from the point of view of the law books, but from the point of view of economic development. If Government and business for once understand each other, one-half of the problem of successful cooperation among American business men for legitimate and necessary ends will be solved.

If Congress has been suspicious of business, business men are in a measure to blame for this condition. Too frequently they have neglected and refrained from coming in contact with members of Congress. If the business men of this country would take an interest in the work of their Senators and Congressmen and endeavor to confer with them frequently on the many problems with which they have to contend, I am sure they will find that the Senators and Congressmen will be willing and anxious to learn the facts about business. If business men will do their part by taking an interest in public affairs, they may rest assured that the Senators and Representatives will be only too glad to do theirs.

When I went to Washington I thought, in common with many other business men of the country, that Senators and Representatives were in Washington to do as they pleased, frequently ignoring the wishes of their constituents, particularly those who happened to be business men. My practical experience in Washington satisfies me that I was mistaken. The members of Congress wish to do the right thing by the people of the country. We cannot expect them, however, to be familiar with business problems unless we take an active interest in bringing the facts of business to their attention. It does not create a good impression if the only time Congressmen hear from business men is when some question comes up before Congress to be voted on. We must do something more than respond to the request of the secretary of some association to send a wire. We must take an active interest in public affairs.

Labor has accomplished a great deal in the way of legislation because labor is organized and thinks collectively of its problems. The same is true of the farmers in their work to secure legislation. Business men, however, have received very little in the way of helpful legislation, and the reason in part for this is that they have not approached their Congressmen in a proper spirit and because they have not put themselves out to co-operate in a sympathetic, cordial way with them.

It is my belief that the business men of the country now fully appreciate that Government wants to help them. We must, however, lay aside our former critical attitude. We must face the problems practically and sympathetically. We must not allow our prejudice to affect and bias our better judgment. We must be business men first. If we do this, I am sure that we will receive what we are entitled to.

Trade Journal's Part

Many suggestions have been made by writers and lawyers, of note, by captains of industry and legislators, prescribing different remedies for improving business conditions. There

is no one remedy that will give relief to all our ills. What will help one industry may injure or kill another. But there are a few fundamental principles upon which may be based the diagnosis and treatment of ailments of business.

Breadth of Outlook Essential

In last analysis success in business depends upon the intelligence of the individual manufacturer. If he does not understand both the details and the broad aspects of the industry of which he is a part, he cannot expect to be successful. American business men do not realize the value which trade journals and technical magazines may be to them in increasing the efficiency of their factories and in giving them a broad and comprehensive view of their business. Our foreign competitors read almost every article published upon their business with great care and thoroughness. Many of them have duplicate copies of their favorite trade papers sent to their homes so that they may read them away from their business without being disturbed. Many foreign manufacturers contribute articles to these journals on phases of the business with which they are most familiar. Such articles are bound to be helpful and have a constructive effect. Our trade journals and technical papers are the best in the world and they should be encouraged and supported by our business men. Copies should be placed where employees can see them and they should be urged to read and study them. These papers are preaching the gospel of sound business on practical lines and are helpful not only to business but to the country as a whole. If the suggestions made by them in the past had been followed by our business men it would not be necessary at this time to point out some of the fundamental weaknesses in American business.

Millington Converter Makes 2-Ton G. M. C. Into a Four-Wheel-Drive Truck

THE Millington Auto Engineering Co., Chicago, is putting on the market a standard set of parts for converting a G. M. C. 2-ton truck into a four-wheel-drive machine. In rearranging the car to take this new form of drive, 90 per cent of the standard parts are maintained without interference. The front axle, however, is largely reconstructed.

The Special Axle

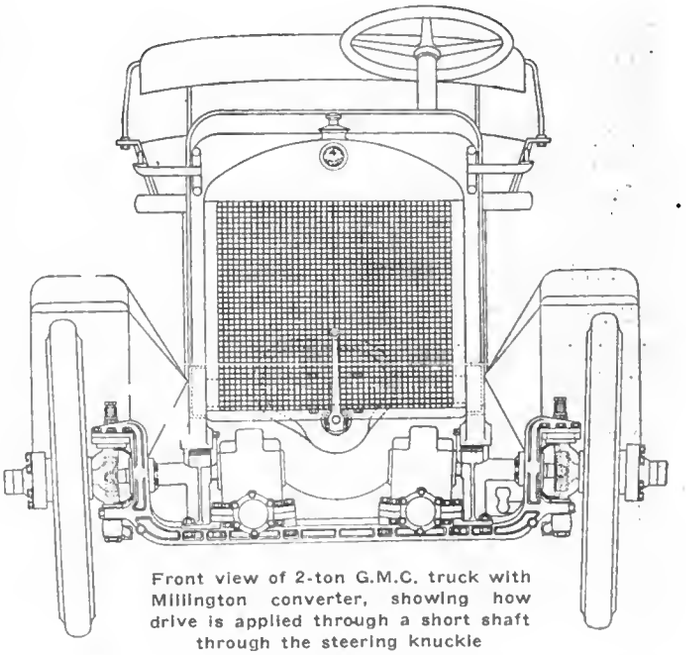
The new axle is drop-forged nickel steel fitted with a hollow spindle of the same material and stub shafts of chrome vanadium steel. Timken driving plates, hubs and bearings are used and the drive is by Timken-David-Brown worms.

The accompanying drawings illustrate the method of applying the Millington four-wheel-drive to the truck. It will be noted there are two parallel shafts running forward on either side of the engine carrying the drive to the front axle at two points. From each of these points the propulsion is transmitted by a short shaft through the steering knuckle, which contains a bearing, to the wheels. There is also a chain case containing two differentials, one which compensates between the right and left wheels and the other between the front and rear drive. M. & S. differentials are used and the chain is a Whitney silent type working on case-hardened sprockets. The two parallel shafts which carry the drive forward are nickel steel.

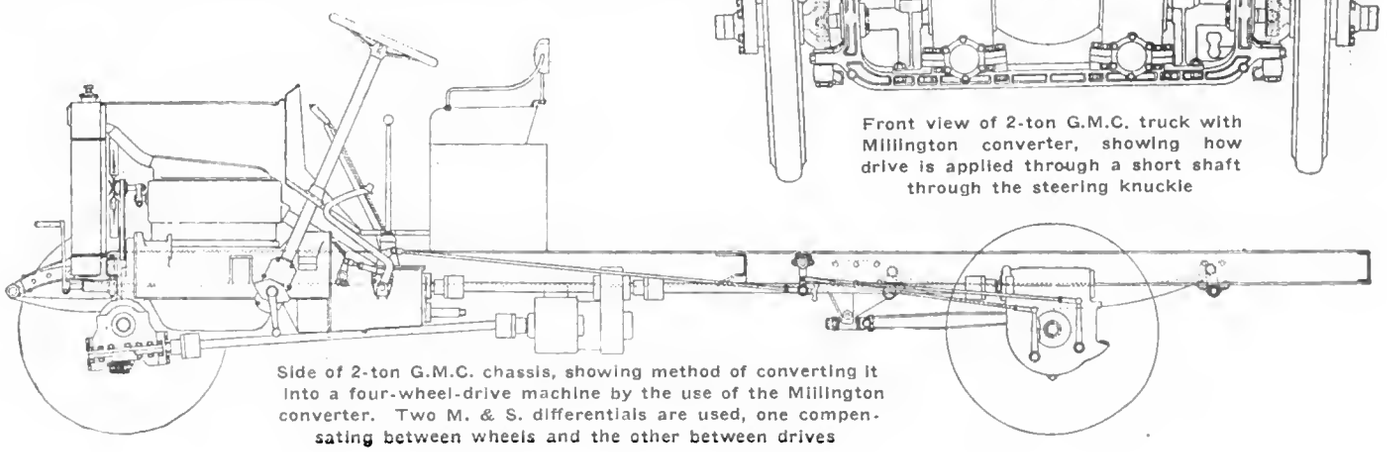
Advantages of the Construction

Some of the advantages which are claimed for the construction are the low center of gravity; location of engine under a hood and low in the vehicle, as well as in the center of the tread; the use of 90 per cent of the standard parts of the machine; perfectly balanced weight, both sprung and unsprung; use of direct drive to the rear axle resulting in the delivery of the greater percentage of power where the greater percentage of load is carried; and the general conformation to standard practice in the design and appearance of modern motor trucks.

A tensile strength of 120,000 lb. is claimed for the axle, and the same strength obtains for the hollow spindle and the stub shafts.



Front view of 2-ton G.M.C. truck with Millington converter, showing how drive is applied through a short shaft through the steering knuckle



Side of 2-ton G.M.C. chassis, showing method of converting it into a four-wheel-drive machine by the use of the Millington converter. Two M. & S. differentials are used, one compensating between wheels and the other between drives

Gasoline from Natural Gas—II

Gas Consists Almost Entirely of Paraffin Hydrocarbons—Only Gas Rich in Gasoline-Yielding Members Suitable for Use in Compression and Condensation Process

By Bernard N. Glick

¶ EDITOR'S NOTE:—According to government reports the casing head gasoline industry, or production of raw gasoline from natural gas, increased 53 per cent in 1915 over 1914, an average price of 7.9 cents per gallon being received for the unblended product. The same authority estimated that 24,000,000,000 cu ft. of natural gas was utilized, with an average recovery of 2.57 gal. of gasoline per 1000 cu. ft. Mr. Glick has made an exhaustive study of this growing industry with a view to its possibilities as a relief to the situation caused by the ever-increasing demand for gasoline. First part of this article appeared in THE AUTOMOBILE *for Nov. 2.*

THE question of the origin of the mineral substances petroleum and natural gas has long engaged the attention of chemists and naturalists. The theories propounded are divisible into two classes, firstly, those ascribing to them an inorganic origin and secondly, those which believe them to be organic decomposition products. It is well known that when water acts on carbides, *i.e.*, compounds of metals and carbon, various hydrocarbons are liberated, the best known example being the formation of acetylene from calcium carbide. Chemists like Berthelot and Mendelieff were staunch supporters of the inorganic theories founded on observations of the nature of the preceding example. On the other hand, there is an extensive and overwhelming mass of evidence which seems to prove that petroleum and natural gas are produced by the decomposition under natural conditions of matter of both vegetable and animal origin. As examples of this sort of evidence it is known that on distilling menhaden (fish) oil a petroleum-like liquid is obtained, while on the Swedish coasts petroleum is found as a decomposition product of seaweed under ordinary atmospheric conditions. In what state the product we know as natural gas exists in the earth is a point not yet definitely settled, but from a consideration of the temperatures and pressures of liquefaction of its constituents it seems highly probable that it exists in the earth's strata in the gaseous state, as the temperatures prevailing there are not low enough nor the pressures high enough to keep it liquefied.

Gas Consists of Paraffin Hydrocarbons

Chemical analysis has shown this gas to consist almost entirely of a mixture of the paraffin series of hydrocarbons, the lowest members methane and ethane predominating. Both these compounds are gases at the ordinary temperatures, methane having a boiling point of —160 deg. C. and ethane —93 deg. C. Associated with these are varying amounts of the higher members propane and butane, gases with boiling points of —45 deg. C. and 1 deg. C. and pentane, hexane and heptane, liquids with boiling points of 36.4, 68.9 and 98.4 deg. C. These higher liquid members are retained in the gas just as moisture is retained in the atmosphere and the amounts present depend on the same factors, temperature, pressure, and the intimateness of contact between gas and liquid. In the case of natural gas there is an added factor due to the varying composition of the liquid phase of the system, namely the percentage of low boiling fractions in the oil with which it is associated, for if the oil is high in these it is natural that the gas in contact with it should abstract a relatively larger amount of them. According to its composition natural gas is divided into two varieties, "wet" or casing head gas, and "dry" gas.

By wet gas is meant gas rich in the higher gasoline-yielding members, pentanes, hexanes, etc., usually a gas occurring along with oil and containing from 60 per cent and upward of these compounds. Dry gas consists mainly of methane, varying in amount from 50 to 95 per cent. This variety of gas is very rare in oil fields but common enough in gas fields, the Hogshooter field in Oklahoma yielding a gas which is almost entirely methane. The interest in this distinction lies in the fact that only wet gas is suitable for the production of gasoline by compression and condensation methods.

The manufacture of gasoline by compression and condensation is essentially a physical process. The paraffin hydrocarbons, as their name implies (parum, little, affinis, affinity), are very inert substances and as they are fully saturated compounds, the likelihood of chemical action merely on the application of pressure and cooling is exceedingly remote.

Physical Properties

In order to understand the methods of manufacturing gasoline from natural gas under consideration, one should have some idea of the physical properties of gases. The gaseous, liquid and solid states are common with few exceptions to all substances, the particular state in which they exist at any time being determined by the temperature and pressure then prevailing. Thus at atmospheric pressure we know that ice, water and steam are different states of the same substance, the particular state depending on the temperature. All known gases when exposed to certain conditions will pass from the gaseous to the liquid state and vice versa. These conditions, however, must be observed before liquefaction can be brought about.

For example, take the case of methane, the main constituent of dry gas. If we attempt to liquefy this gas by compression at any ordinary temperature no amount of pressure will succeed in doing so, and this is true for all temperatures above —82 deg. C. At this point a pressure of 55.8 atmospheres of 837 lb. to the square inch will liquefy it. This temperature above which it is impossible to liquefy a gas is called the critical temperature and the pressure necessary to liquefy it at that temperature is the critical pressure. Every gas has its own particular critical constants and if we wish to liquefy any gas by compression we must make sure the temperature is below the critical point. Once below this critical point the pressure necessary for liquefaction depends on the vapor pressure exerted by the gas at the temperature used, and this becomes less and less the further we get below the critical temperature.

Another theoretical consideration has to be taken into account also. If we exert a pressure on a mixture of gases the pressure on any individual gas in it is proportional to its

percentage of the whole. Thus if a natural gas contains 20 per cent of gasoline vapors and we exert on it a pressure of 250 lb. per square inch, only 20 per cent of that pressure, namely 50 lb., is being exerted on the gasoline vapors themselves.

Bearing these principles in mind, let us apply them to natural gas and see what are the possibilities of liquefying its constituents.

Vapor Pressure a Determining Factor

The critical temperatures of all except methane are above atmospheric temperature, so methane is ruled out with all the others as possibilities, the vapor pressures at the temperature of cold water around 10 deg. C. being the determining factors now. These are as follows:

Vapor pressure (lb. per sq. in.), approximate—Ethane, 250; propane, 104.4; butane, no figures available; pentane, 5.4; hexane, 1.5; heptane, 0.4.
Temperature—Ethane, 10°C.; propane, 12.5°C.; pentane, 10°C.; hexane, 10°C.; heptane, 10°C.

Thus with a gas composed of 100 per cent ethane it would be possible at a temperature of 10 deg. C. to liquefy it by a pressure of around 250 lb. With a gas containing the more normal amount of 50 per cent, a pressure of 500 lb. would be necessary and as such pressures are never used, ethane is not liquefied. With 30 per cent propane, around 350 lb. would be necessary and as this pressure is sometimes attained, some propane will be liquefied. With the higher members even 5 per cent of pentane only requires 108 lb. for liquefaction and 2 per cent of hexane and heptane require only 75 lb. and 20 lb. respectively. Thus using cold water as the cooling agent and pressures up to around 350 lb. per square inch we may expect to find in the condensate propane and the higher members in liquid form. Dissolved in the liquid will be quantities of the gases methane and ethane as they are soluble in the liquid hydrocarbons in amounts varying directly with the pressure employed. Now, suppose one had condensed such a liquid at 350 lb. pressure, what would be the effect of exposing it to atmospheric conditions? The boiling points of the various liquefied paraffins are as follows:

Propane—45°C.; butane, 1°C.; pentane, 36.4°C.; hexane, 68.9°C.; heptane, 98.4°C.

The average temperature of the atmosphere may be taken as 20 deg. C. (32 deg. C. in summer and 4 deg. C. in winter.)

Pressure Must Not Be Too High

Since propane and butane are gases under atmospheric conditions they would volatilize immediately from the liquid and in doing so would carry along with them part of the liquefied hydrocarbons, pentane, hexane, and heptane, just as on boiling water, the air escaping takes water vapor with it. Moreover, the methane and ethane dissolved in the liquid at 350 lb. could not be held in solution at atmospheric pressure (15 lb.) and they would therefore escape taking with them more of the true condensate. From this we see that by using too high a pressure in condensing we get a very unstable condensate. We realize then that the conditions to aim for in working are such that the liquid condensate produced should contain just as much of the lower members as can be retained by them under ordinary atmospheric conditions.

Since the composition of the gas used is the most important factor in the success or failure of a gasoline condensation plant, the testing of its suitability for this purpose is highly important. An ordinary eudiometric analysis such as is usually given is of little value in determining the amount of condensable vapors present, for it is impossible by this means to identify the amounts of each individual constituent.

Interesting work along these lines, however, has been done by the Bureau of Mines by liquefying the gas with liquid air and fractionally distilling the liquid in vacuo at different temperatures. One of the most valuable tests employed is based on the fact that natural gases are soluble in various solvents in volumes directly proportional to the amounts of higher gasoline producing hydrocarbons present. The solvents generally employed are claroline oil (a mineral oil distillate, specific gravity 0.8667 flash point by Pensky Martens closed test 152 deg. C., ignition point 270 deg. C.) or alcohol, and the gas should be soluble to the extent of 30 per cent or more by volume as determined by agitating 100 cm. of the gas with 35 c.c. of the former or 50 c.c. of the latter. In a further test advantage is taken of the wide variation in specific gravity of the constituent members of the gas. Methane has a specific gravity of 0.554 (air = 1), ethane 1.049, propane 1.520, butane 2.01, the still higher homologues increasing rapidly.

SPECIFIC GRAVITIES AND ABSORPTION NUMBERS OF SAMPLES OF NATURAL GAS USED FOR MAKING GASOLINE

Situation	Specific Gravity Air = 1	Absorption No.
Follansbee, W. Va.	1.46	86
Follansbee, W. Va.	1.41	84
McDonald, Pa.	1.03	39
McDonald, Pa.	1.59	43
Klefer, Okla.	.83	28
Follansbee, W. Va.	1.38	65
Riverside, W. Va.	1.37	48
Riverside, W. Va.	1.38	44
Steubenville, Ohio	1.21	54
Steubenville, Ohio	1.00	37
Glen Pool, Okla.	1.15	55
Glen Pool, Okla.	1.43	78

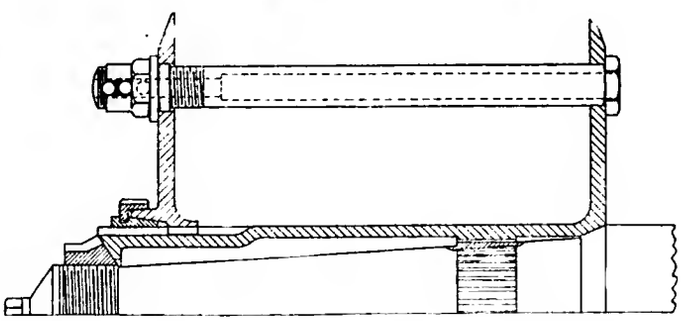
0.80 Lowest Gravity Limit

From these figures it will be seen that just as in the case of the absorption number, the specific gravity of the gas increases directly with the percentage of gasoline producing constituents, and it has been found advisable to fix 0.80 as the lowest limit for a gas to be used on a commercial scale. The determination itself is simple, a glass bulb being weighed full of air, when exhausted, and full of the gas to be tested, the ratio of the weights of these equal volumes of gas and air giving the specific gravity. While these two tests give a fair line on the value of the gas, it has become customary to amplify them by trying out the gas practically with a small compression apparatus put up for the purpose by many of the firms supplying compressors for the actual plants.

These gases give on condensation from 1 to 4 gal. of gasoline per 1000 cu. ft., any gas giving less than ¾ gal. per 1000 cu. ft. not being considered rich enough for commercial exploitation.

This industry will certainly produce during 1916 well over 100,000,000 gal. of "casing head" gasoline and will come on the market as a blend with various petroleum distillates. The total volume sold as a motor fuel will be in the neighborhood of 200,000,000 gal., which at 20 cents a gallon will be worth $40,000,000.

Detachable Aeroplane Propeller Hub



At the first meeting of the Aeronautic Engine Division of the Society of Automobile Engineers Standards Committee, Howard E. Coffin suggested that a quick-detachable propeller hub could easily be made on the principle of the detachable automobile wheel. The illustration at the right shows a British patent recently granted to the Rolls-Royce Co. It will be seen that the hub is closely similar to that used for the Rudge-Whitworth detachable wire wheel.

The FORUM

Wants Lower Second Gear

By O. B. Parkinson.

THE writer has driven automobiles of various makes in California mountains for 14 years, and over every condition of road which can be found in California, and from his own experience, and that of hundreds of others whom he has met in his travels, is thoroughly convinced that 90 per cent or more of the cars manufactured in the East, and sold in California, are not as well adapted to use in California as they could be with the proper understanding on the part of the makers of gear ratios as applied to road conditions here. If this is true, then the fact that California is well up to the top of automobiles registered, should interest the car makers to the extent of giving the subject due consideration. A few have done so. Many of the makers have changed their low speed gear ratio for lower ratios, and there stopped, with the idea that having geared the car low enough to climb the California mountains on low gear, that is all that is necessary.

A few years ago for an average four-cylinder touring car of 30 hp., the high speed ratio was 3.5, the second was 6.25, and the low, 11.2 to 1. This produced at a maximum engine speed of 1200 to 1500 r.p.m., a car speed on high gear of from 50 to 60 m.p.h. on second, about 20 to 25 m.p.h., and on low, from 10 to 15 m.p.h.

Low Gear Too High

For grades exceeding 25 per cent on rough mountain roads, of which there are many in California, the low gear was not sufficiently low. In order to negotiate such hills sucessfully, a maximum engine speed must be developed which resulted in damage to the car, and discomfort to its occupants.

The modern cars have a high speed gear ratio for ordinary stock cars, ranging from 3¾ to 4½, with a second gear of from 6 to 7, and a low gear of about 13 to 14 to 1; one light car having a ratio of 16.8. These low gear ratios should be ample for any car. Take the average car with the 4½ : 1 high gear, its maximum car speed is about 45 to 50 m.p.h.; on its second speed it will develop a car speed at a maximum of about 30 m.p.h.; with its slow speed it has a maximum car speed of approximately 10 to 12 m.p.h.

No Real Intermediate Speed.

Now, it will be noted that in these cars the second gear, is only about 2 or 3 ratios lower than the high speed gear, while the gap between this intermediate gear and the low is 6 to 8 gear ratios. This, on the face of it, looks strange, and unless there is a good reason for it, is absurd. If there is a good reason, we have failed to find it, on the contrary, from the writer's own experience and the experience of others with different makes of cars, it is a fact that on rough mountain roads with many of the popular makes of cars, that a grade which cannot be negotiated on high speed, cannot be negotiated on second, and the operator is obliged to drop back to low gear.

Could Easily Be Changed

With a reasonably low second speed, he should negotiate all grades up to 18 or 20 per cent on second, and at a car speed of 10 to 12 m.p.h. (which is as fast as the average mountain road should be traveled).

It is not only in ascending hills in which a lower second speed is required, but in descending them as well. We have many California roads where the hill is from 5 to 10 miles long with grades ranging from 5 to 15 per cent, where the conditions are such that to travel down hill on high gear is dangerous, to use the usual second speed is but little better, and to travel on low gear is too slow. A lower second gear, which is really an intermediate, that is midway or nearly so between the high and the low, is a great advantage.

If there is anyone who can advance any good reason why a car should be geared in the proportion 4, 6, and 16, for the use of the average tourist, I should like to hear it. There is no question but that many cars which have failed to make good in the mountains of California with the resultant loss of sales, could be changed easily to fit all the requirements of the drivers in mountain work.

What Is 100 Per Cent Grade?

By Chas. E. Manierre

THERE is quite generally a confusion of terms in describing road grades. Occasionally one makes use of the angular difference between the horizontal and the grade correctly describing it as 3 or 5 or other degrees, in which case he means 3 or 5 or other degrees of arc, as shown in the first of the small diagrams.

Unfortunately the word "degree" in its wider meaning can be applied in connection with the other two modes of indicating grade, although of course erroneously. The surveyor's and engineer's method of describing grade is so many feet in 100, the hundred being measured along the level and the amount of elevation at right angles thereto.

Automobile vs. Surveying Terms

In each of the small diagrams the distance from *A* to *C* is the grade of the road and the line or distance between *A* and *B* is horizontal. In the second diagram the road grade is not drawn, so that the lines used by the surveyor may stand out more prominently. The base, *A* — *B* is generally taken at 100 ft. and the perpendicular, *B* — *C* is the number of feet of rise in the hundred. The surveyor's expression is 5 ft. in 100, 10 ft. in 100, etc. When the rise reaches 50 in 100 it may be described as 50 in 100 or 1 in 2, and similarly, when it reaches 100, it may be described as 1 in 1. A still steeper grade would be represented by 2 in 1. Those who have had anything to do with land matters know that practically all of the surveyor's work is reduced to the horizontal, and in fact even when he is chaining up a hill, his chain is always held level.

For those in any way interested in the automobile, whether in driving, designing or manufacturing, it is the distance along the grade that is measured and compared with the vertical, as shown in the third of the small diagrams, in which *A* — *C* is deemed to be 100 ft. and *C* — *B* is the vertical rise, and the two are expressed as percentage. If *B* — *C* equals

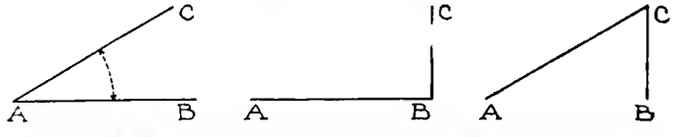


Fig. 1—Diagrams illustrating how the civil engineer contrasts the base of the right angle triangle with the vertical, while the automobilist contrasts the hypothenuse of the triangle with the vertical

three, the grade is a 3 per cent grade. If it equals 5 or 10 it is a 5 or 10 per cent grade, and so on. In other words, the engineer contrasts the base of the right angle triangle with the vertical, while the automobilist contrasts the hypothenuse of the triangle with the vertical.

The larger diagram shows the three methods of describing grade in a single drawing, so that the relation between angles, per cent and rise in the hundred may be apparent, showing the interchangeable values of a number of grades, as expressed in any of the three ways.

Three Methods of Describing a Grade

The line *A* — *F* is approximately the steepest grade that an automobile is expected to ascend. Very few can do better and many will not reach it. An engineer would describe it as 60 in 100. It is also properly to be described as a 50 per cent grade, because the perpendicular drop from the point *K* is exactly half the length of the line *A* — *K*, and it can also properly be described as a grade which makes with the horizontal an angle of 30 deg. of arc.

The 45 deg. line, from *A* to *L* is drawn as a matter of interest, because, from an engineer's standpoint, the horizontal distance and the rise being equal, it is properly described as 1 in 1 or 100 in 100 and it is very improperly described as a 100 per cent grade, which it is not. It is, in fact, approximately a 71 per cent grade. It should be here said that the degrees are only approximately correct, and this is true also of all the figures relating to the grades of 5, 10 and 15 per cent, the errors being too slight to be noted.

45 Deg. Not Really a 100 Per Cent Grade

The absurdity of calling the 45 deg. grade a 100 per cent grade is brought out by considering that it is perfectly possible to have steeper grades, as for example railroad embankments, so that one would proceed to 150 and 200 per cent grades, and at the point where the slope merges into the perpendicular, under this system of nomenclature, the grade becomes infinite.

On the other hand, there are very strong reasons for applying the per cent term to the grades that are designated by measuring along the slope and comparing that with the perpendicular. The horizontal is, of course, a zero grade. As the perpendicular is approached the grade per cent increases to 90 per cent and above, but at the point where the perpendicular is reached, the grade is 100 per cent. In other words, it is all grade and no horizontal advance.

Should Measure Grades in Per Cent

There is also the additional reason for using the per cent term, that where the weight of a vehicle is expressed in tons of 2000 lb., each rise of one per cent of grade requires an addition of 20 lb. of engine torque per ton to overcome it. That is to say, if a car is proceeding on the level and comes to a 10 per cent grade, its reserve torque must be at least 200 lb. per ton to carry it up the grade. If the grade increases to 15 per cent an additional 100 lb. is needed, and so on.

Fortunately for the average owner the practical difference between 15 per cent and 15 in a hundred and any lesser grade is too slight to take into account, and on the main highways a grade exceeding 15 per cent is scarcely ever met with. It is said that the grade up Pike's Peak does not exceed 10 per cent at any point. Occasionally on back roads 20 per cent or 25 per cent grades may be encountered, but in those cases it it frequently the bad character of the road bed that troubles the driver quite as much as the steepness, or degree of incline, of the road.

Take 7 or 8 per Cent Grades on High

The average automobile, if in good condition, should be able to surmount a 7 or 8 per cent grade on high gear. The effect of reduction to low gear and the enormous increase in reserve torque applicable to the surmounting of hills are illustrated when one multiplies 40 or 50 per cent of grade by the 20 lb. for each per cent of rise and finds that for the weight of his car in tons the engine must furnish on account of grade alone 800 to 1000 lb. respectively of energy, a very considerable expenditure.

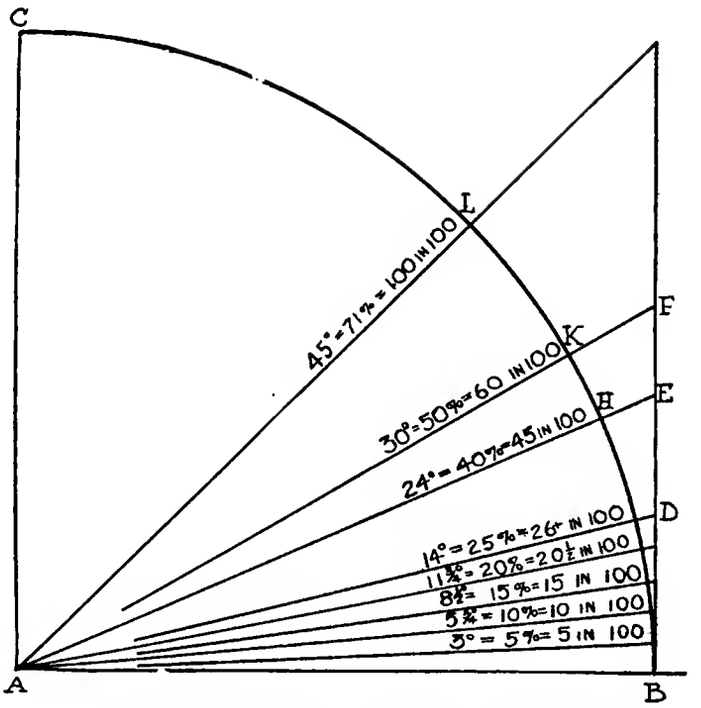

Fig. 2—Three methods of describing grade in a single drawing so that the relation between angles, per cent and rise per hundred feet may be apparent, showing the interchangeable values of a number of grades as expressed in any of the three ways. The line A-F is approximately the steepest grade an automobile is expected to climb

Confusing to the Car Buyer

It may be noted also that so long as the terms descriptive of grade are confused, the purchaser may do injustice to the manufacturer who claims an ability in his car to climb a 50 per cent grade, if his mind is taken up with the idea that it is a grade of 50 in a hundred, whereas the claim is 60 in a hundred and the engine power proportionately larger. On the other hand, if the manufacturer claims an ability of his car to climb a 60 per cent grade and what he means is 60 in a hundred, the purchaser may erroneously believe that he is claiming for his car the extraordinary ability to climb a real per cent grade, requiring the putting forth of 1200 lb. per ton of torque for the sole purpose of overcoming grade alone, a claim which would be apt to discredit the rest of the statements made with respect to the car, although they might be really true.

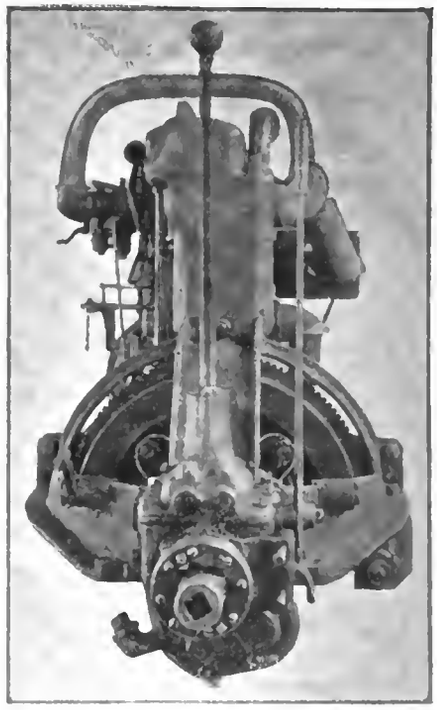
It is to be hoped, therefore, that both makers and users of cars will differentiate between so many feet in a hundred, the engineer's terms for grade, and per cent grade, which has to do with gravitation and which is so intimately connected with engine ability.

Transverse Tables Aid in Solving Problems

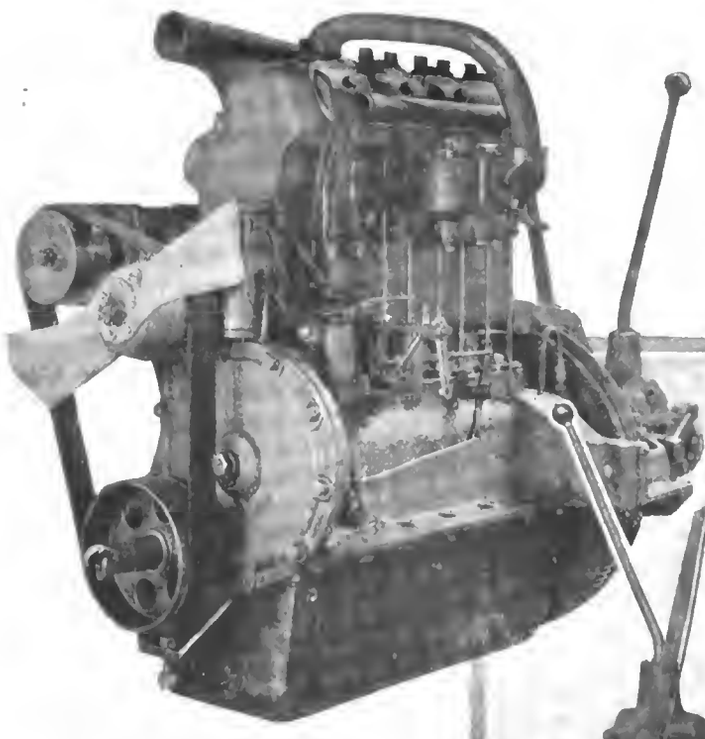
For the convenience of anyone who may wish to make further comparisons of the three ways of expressing grade, it may be suggested that the tables, used by all seamen and surveyors, showing angle, distance, latitude and departure, and known in surveying as Traverse Tables, will quickly furnish them the means of solving all the triangles, these tables having the elements of all possible right angle triangles set down with a sufficient degree of accuracy for the purpose of calculation and comparison.

Monroe Adds Touring Car

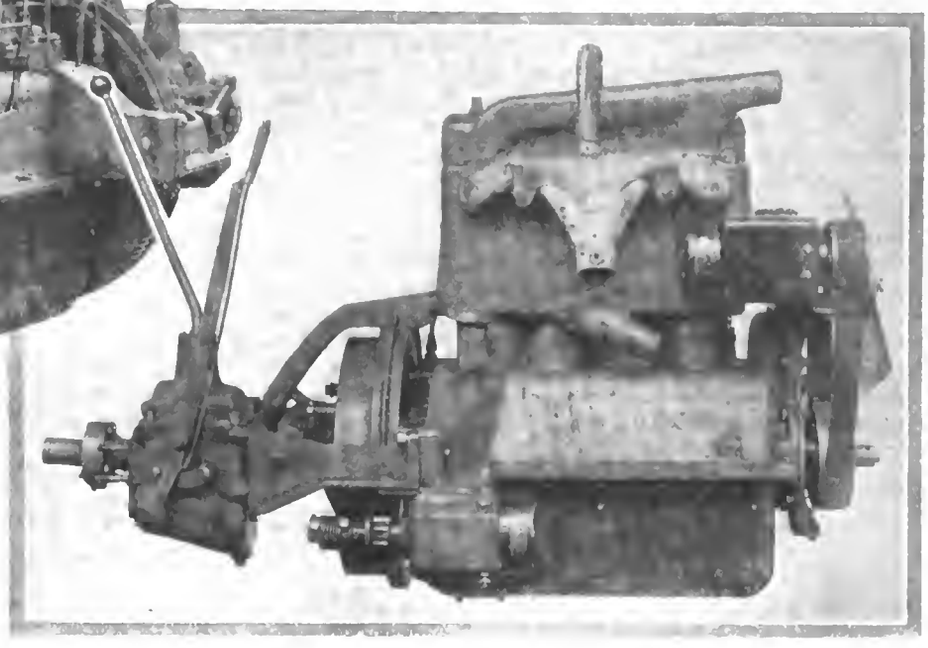
New Car Has 115-In. Wheelbase, Overhead Valve Engine with Detachable Cylinder Head —Dry-Plate Clutch and Cantilever Springs



At the right is a rear-end view of the four-cylinder block unit power plant used in the new Monroe touring car. Note attachment of gearset and hot-air carbureter connection



The view of the engine shown above gives an idea of the belt drive used for the two-bladed aeroplane-type fan and the generator. Ignition unit drive and high mounting of carbureter are also illustrated



At the right is the exhaust side of the engine, illustrating the liberal exhaust manifold, generator and starter motor mounting and Bendix drive of latter

MONROE cars have hitherto been made only as roadsters, but the Monroe Motor Co., Pontiac, Mich., has now added a touring model. The new car, designated as model M-4, is a roomy 115-in. wheelbase vehicle with the modern straight-line center cowl effect, and embraces the latest in construction ideas, particularly in the frame, which is the deep-section design in which the mud aprons and running boards are part of the structure.

Everything about the car is very much in line with the latest tendencies. The overhead valve engine, detachable cylinder head, big valves, dry-plate clutch, slanting windshield and cantilever springs are a few of the high spots chosen at random to illustrate that the latest practice in everything has been studiously followed in this moderate-weight touring car which is to sell for $985 f.o.b. Pontiac, Mich.

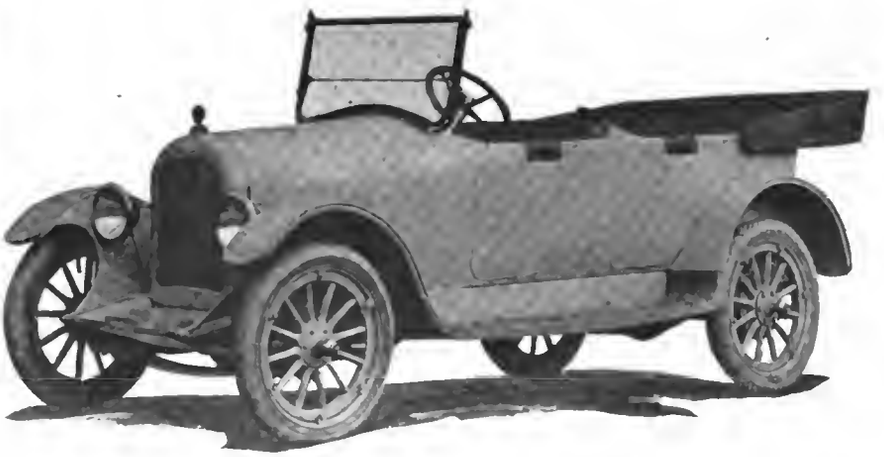
Even a casual inspection of the power plant will disclose its high-speed characteristics. The ports are large and the overhead valves are carried directly in the head. There are no sudden bends in the gas passages as the intake manifold is integral with the engine head.

The cylinder block is cast integrally with the upper part of the crankcase. It is of gray iron. The dimensions of the cylinders are 3¼ by 4½ in., giving a piston displacement of 150 cu. in. The entire combustion chamber is exposed by the removal of the upper part of the engine formed by the head casting, and the valves are also very accessible, as the push rods are carried down on the outside, and there is also no difficulty in reaching them from above by removing the nuts from the top.

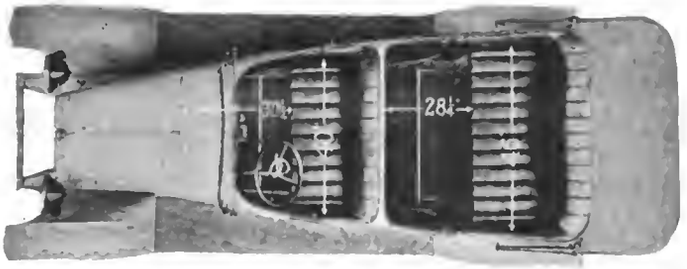
A two-bearing crankshaft is used with two large babbitt-lined bearings. The front bearing is 1¾ in. by 2 7/16 in. in diameter and length and the rear bearing is 2¼ in. diameter by 3 in. length.

Force-feed lubrication is used with a hollow crankshaft through which a gear pump, driven off the camshaft, forces

Rear view of the new Monroe touring car, showing platform spring. Plan appears below



The new Monroe four-cylinder, five-passenger touring car, which sells for $985, f.o.b. Pontiac, Mich. It has a 115-in. wheelbase, and uses 32 by 4-in. tires



the oil to all bearings. There is a pressure gage on the dash which indicates at all times when the system is working. Carburetion is taken care of by a Zenith instrument and ignition by the Connecticut system driven off the camshaft. Both the carburetion and ignition are very simple, as far as the driver is concerned, the carbureter having a fixed adjustment which need not be altered after the car has left the factory. The gasoline tank is carried at the rear of the chassis frame, and has a capacity of 14 gal. The feed to the carbureter is by gravity from the Stewart vacuum feed tank.

Starting and lighting is accomplished by a two-unit Auto-Lite system in which the generator is belt-driven while the starting motor engages with the ring gear on the flywheel by means of a Bendix attachment. The battery is a Willard. This gives a very compact electrical layout and the same idea of clean-cut electrical mounting is noticeable in the ignition where the coil and timer-distributer are side by side. This cuts the length of the high-tension leads, lessening the electrical loss through leakage and resistance.

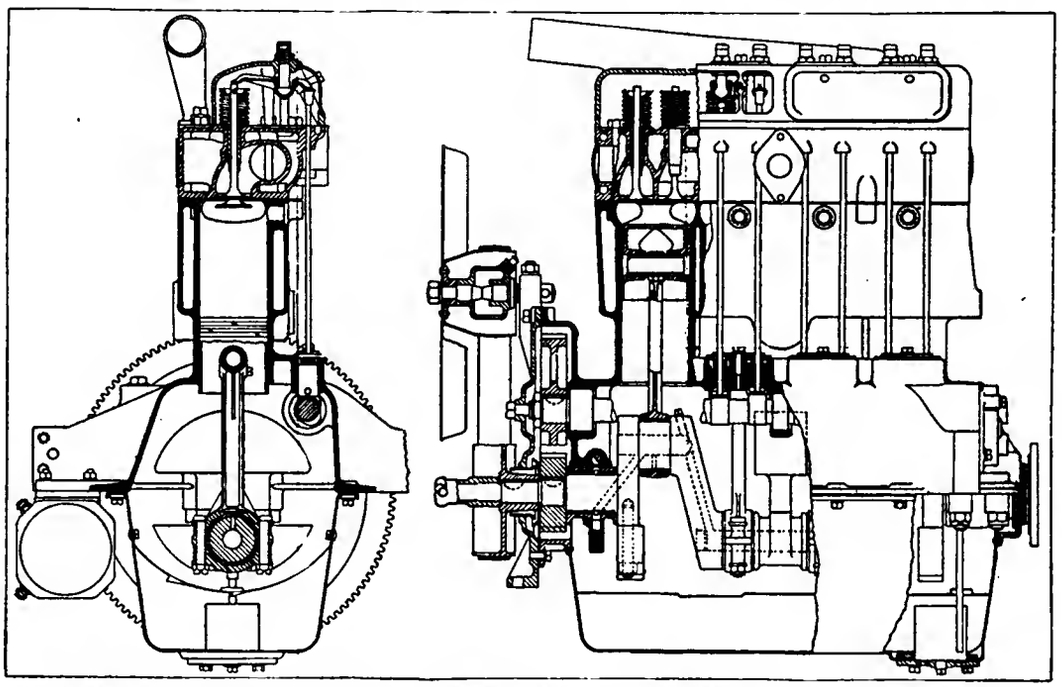
A multiple-disk clutch having six dry plates is used to transmit the power from the engine. The clutch is housed within the flywheel and transmits the drive through a facing of Raybestos against steel.

From the clutch the drive passes through a three-speed gearset which is a part of the unit power plant formed by engine, clutch and gearbox. The materials used in the construction of the gearset are chosen for their rigidity and the gears are made of double heat-treated nickel steel. Ball bearings are used for the main and counter shafts.

M. & S. Differential Used

Two universals are used on the drive shaft and the rear axle is a floating design with a pressed-steel housing and axle shafts of alloy steel. The axle housing is reinforced by the insertion of nickel-steel tubing. The pinion and ring gear are spiral bevels and a factor in the lightness of the axle is in the keying of the rear wheels directly to the outer ends of the live axle shafts. The reduction in the rear axle gives a clew to the high-speed characteristics of the engine, as it is 4¾ to 1. Another feature of interest is in the use of the M. & S. differential as stock. This differential is noted because of the fact that it gives traction on both wheels.

The wheels are artillery type, with twelve spokes. They are made of selected hickory and have spokes of 1⅝ in.



Sectional view of the four-cylinder, high-speed block unit power plant employed in the new Monroe touring car. It has a bore of 3¼ and a stroke of 4½ in., giving a piston displacement of 150 cu. in., and the valves are carried directly in the head. The cylinder block is cast integral with the upper half of the crankcase

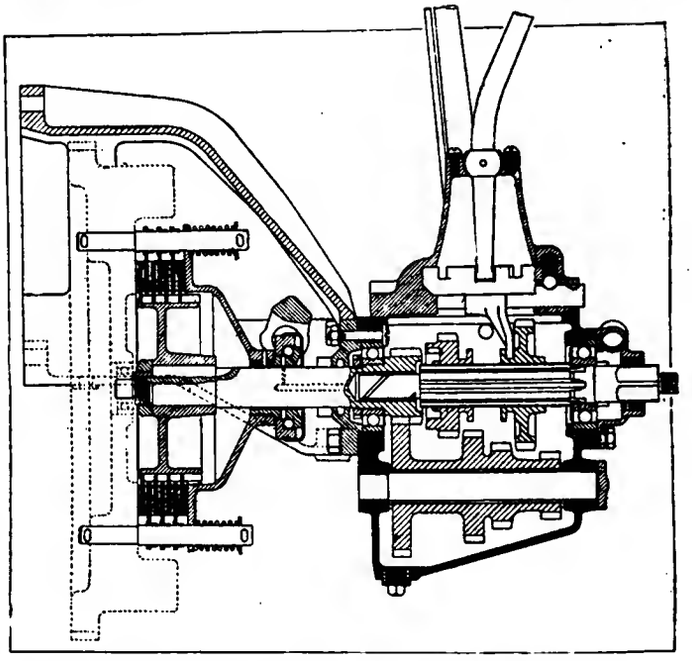
They are fitted with Q.D. demountable rims. Wire wheels can also be secured for the Monroe cars at extra cost if they are desired. The rear wheels carry the brakes, which are double, acting on a single drum 12-in. diameter. The face width of the brake is 1¾ in. and the lining is asbestos fabric. Non-skid tires are furnished on the rear wheels and the tire size is 32 by 4 in. all around.

In the structural part of the frame, the general layout of the Brush deep-side member arrangement is used. The longitudinal members are 6 in. in depth, with the steel running boards, hot-riveted to the side members, forming part of the frame. This design makes it unnecessary to use heavy sills for the body and also does away with the step hangers and the side shields. The entire assembly has the effect of strength with minimum weight.

Compound Cantilever Rear Springs

Compound cantilever rear springs are used, mounted across the rear of the chassis. This type of spring, which is a rather novel type, is noted for its elimination of side sway. In the Monroe application it is fitted throughout with self-lubricating shackles which tend to reduce the necessity for frequent attention and also add to the life of the parts and produces quietness. Semi-elliptic springs of the conventional type are in front.

A full five-passenger capacity is given by the body. The upholstery is in machine-buffed leather and a double cowl effect is secured in the molding of the back of the front seats. The doors are given an added touch by the use of leather flaps. As a comfort feature the upholstery is lined with curled hair and is mounted over cushion springs. Carpet is placed in the rear tonneau and there is space under the front seat for the jack, pump and heavy tools. All the doors have pockets, the front left-hand door being made to carry an assortment of small tools. The finish is in standard black with nickel trim. The fenders are crowned with curved steel running boards having metal-bound lineoleum pads.



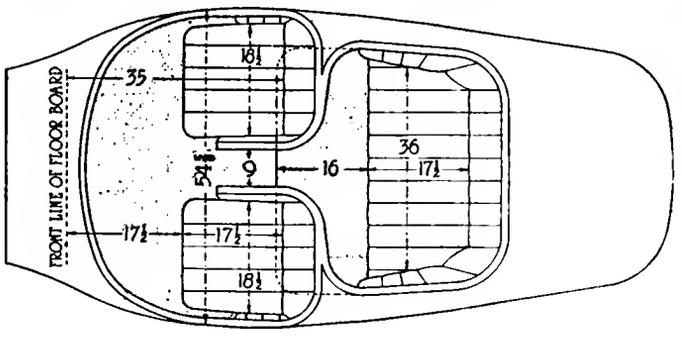
Section through the three-speed-and-reverse gearset used in the new Monroe touring car. Rigidity is a feature of this unit and the gears are of double heat-treated nickel steel. Ball bearings are employed for the main and counter shafts

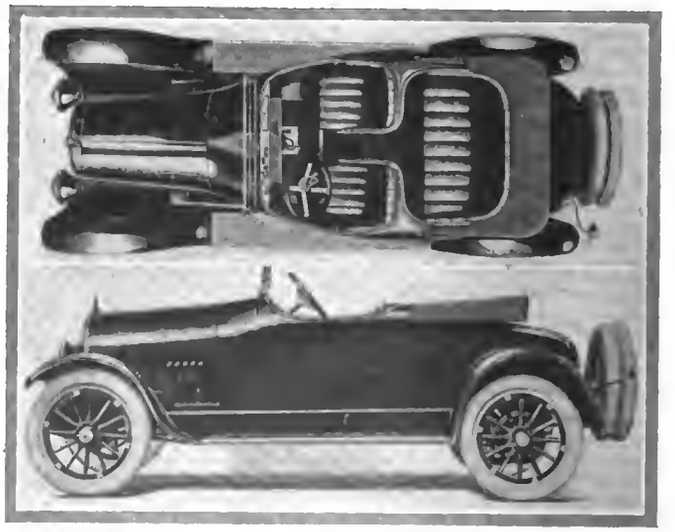
The windshield is sloping with the glass overlapping to eliminate rain leakage.

For a color choice the Monroe company offers royal blue with cream or red wheels. The finish of the metal work is black, as stated. Full equipment is sold with the car, this including besides the accessories mentioned, a heavy rubber one-man top, Collins curtains, electric horn, extra rim and carrier, Connecticut lock switch, Stewart-Warner speedometer, muffler cut-out and complete set of tools.

Westcott Four-Passenger Cloverleaf Roadster

LARGE and comfortable seats are one of the leading features of the new four-passenger cloverleaf roadster recently brought out by the Westcott Motor Car Co., Springfield, Ohio. The seating arrangement in this model has been designed to provide maximum comfort for four passengers. Entrance to the rear compartment is through an aisle 9 in. wide between the front seats. This permits passengers to change from one compartment to an other without interfering with the driver and also insures a pure circulation of air to the rear seat after it is forced to the floor in front of the driver through the double ventilating windshield. This body is mounted on the standard Westcott 125-in. wheelbase chassis. Dimensions are given in the diagram below.





The side view and plan of the new Westcott four-passenger cloverleaf roadster appearing above give an excellent idea of the lines and general appearance of this model, which has a smooth exterior and fenders conforming closely to the contour of the wheels

At the left is a plan diagram giving the dimensions of the seating arrangement

ACCESSORIES

Moore Steering Gear

THIS steering gear head was designed to overcome lost motion or backlash by providing against wear in gears of the worm and sector type. Its construction is evident from the illustration, the two parallel levers *A A* rigidly connecting with the shafts of the sectors *C*. These sectors engage the worm *D* which operates them, the right and left threaded locking screw *B* serving to draw the levers *A A* together or to separate them. By this means the teeth of the sectors may always be kept in contact with the worm, thereby preventing lost motion. When the levers are drawn together the wear comes on one side of the teeth and, when apart, on the opposite side.

Thus the mechanism may be kept in perfect adjustment and all lost motion eliminated until the teeth of the sectors are worn to a knife edge and are no longer strong enough to do the work required of them. One of these gears has been in use for 5 years, frequent adjustments being made always in the same direction and no fault has developed. By the use of the two sectors *C* twice the number of teeth in the gears and double the number of threads of the worm are brought into play giving double the worm service.—V. M. Moore, 5046 Lakeside Avenue, Cleveland.

Dean Knife Timer for Fords

An ignition timer for Ford cars. The contact is made by two tempered steel knives passing over both sides of a tempered distributing terminal, not coming in contact with any other substance or metal. The shell is made of a special metal and is insulated to eliminate short-circuits. The timer is said to facilitate starting in cold weather and to never need cleaning. Price, $1.75.—Tisch Auto Supply Co., 215 Division Avenue, South, Grand Rapids, Mich.

Line Carbureter Heater

A heating coil operated from storage or dry batteries heats the carbureter in this device. The coil is clamped around the bowl of the carbureter and is controlled by a switch on the dash. By closing the circuit heat is generated, causing the gasoline to volatize more readily, aiding easy starting. Price, $3, complete.—Mechanical Utilities Corp., 5 North La Salle Street, Chicago, Ill.

Pennsylvania Bar Circle Tire

Bar Circle non-skid tires have treads of tough black rubber formed into a combination of cross-bars and circles. This construction is claimed to put the rubber where it is most needed and to enable the tires to exceed their guaranteed mileage under normal conditions. Prices of some popular sizes are:

Size	Price	Size	Price
30 x 3	$10.35	34 x 4	$22.50
30 x 3½	13.45	36 x 4½	31.80
32 x 3½	15.45		

Of course, all other standard sizes are obtainable. — Pennsylvania Rubber Co., Jeanette, Pa.

Toscot Belt Coupling

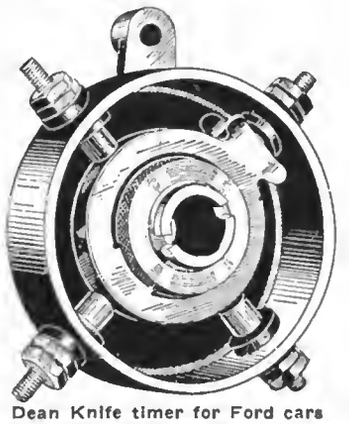
The Toscot is a detachable coupling for flat belts and the Victor for round belts. The former is used in 1 and 1¼ in. sizes for automobile work. Prices of the flat belt coupling run from 90 cents to $2.80 per dozen, according to sizes, ranging from 1 to 6 in. The round belt coupling costs from $2 to $26 per dozen in sizes varying from ½ to 1¼ in.—Stewart & Co., New York City.

Searchlight Torch

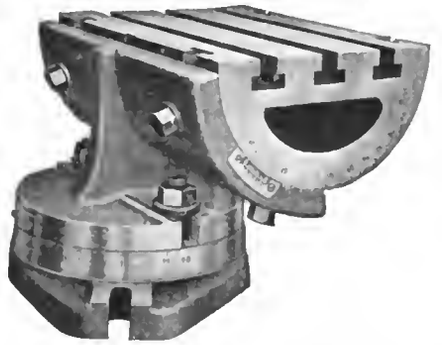
A brazing or soldering torch that may be attached to any automobile or motorcycle acetylene tank. An extremely hot flame is produced immediately and may be regulated to suit the requirements of the work. The device is small, provided with a convenient handle and may be used in a limited space. Price, $1.50.—Searchlight Co., 415 Karpen Building, Chicago, Ill.

Universal Angle Plate

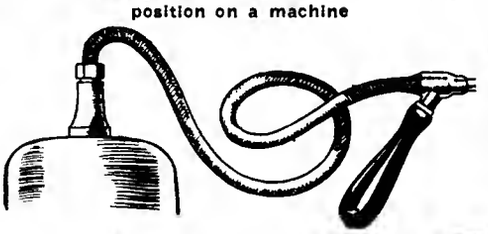
The Universal plate holds the work in almost any position, either in a lathe, planer, milling machine, shaper, drill press, or grinder. A cast iron base is bolted to the machine tool, and carries a double adjustment standard supporting the semi-cylindrical table to which the work is clamped. This standard may be



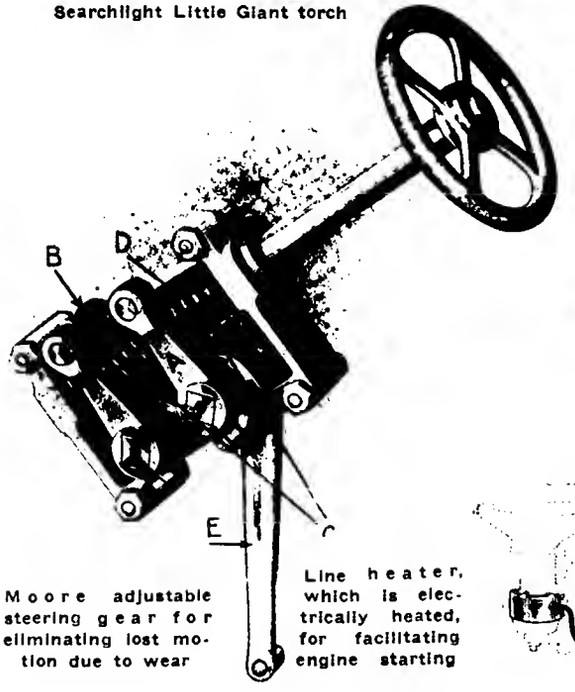
Dean Knife timer for Ford cars



Universal angle plate for holding work in any position on a machine



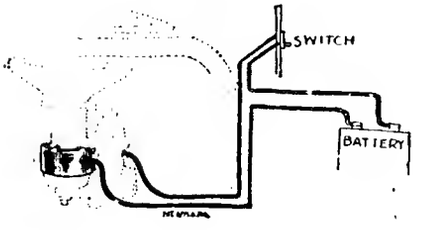
Searchlight Little Giant torch

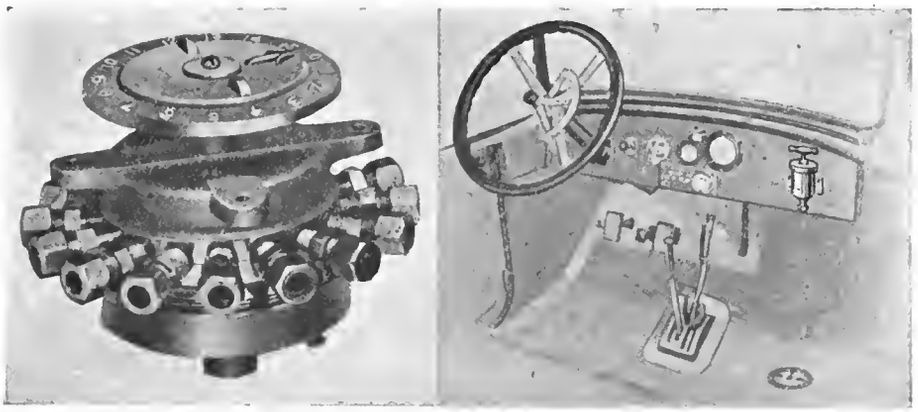


Moore adjustable steering gear for eliminating lost motion due to wear

Line heater, which is electrically heated, for facilitating engine starting

Pennsylvania Bar Circle non-skid tire, showing distinctive non-skid tread





Monitor lubricator. Distributer illustrated at left is mounted under floorboards as shown at right. The device is designed to replace grease cups

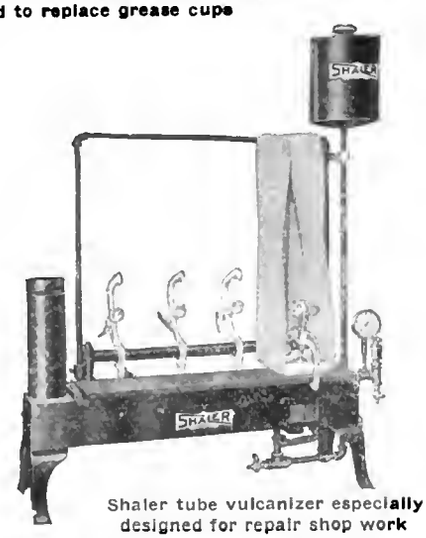
moved through 360 deg. horizontally, and work table may be swung through an angle of 90 deg., the amount each is moved being shown by a scale on the face of the adjusting members. It is said that the work is rigidly held, may be adjusted to any angle while bolted to the table, and is particularly adapted to tool room work. Price, 4 by 6 in., $50; 6 by 8 in., $75; 8 by 10 in., $100.—Boston Scale and Machine Co., 381 Congress Street, Boston.

Monitor Lubricator

Grease cups are eliminated throughout the car, and all grease is supplied by an attachment which is mounted in the driver's compartment. The device consists of a grease gun which is fastened permanently on the cowl and which delivers grease to a distributer sunk in the floorboard. Pipes run from it to the various points on the car which require lubrication. The top of the distributer consists of a dial with numbers placed at points on its circumference, each one corresponding to some pipe running to a point requiring lubrication. If the pointer is turned to number 3, for example, and the handle on the grease gun is screwed down, grease might be delivered to the right front spring bolt. The delivery of the grease to the various points is claimed to be positive, and only occurs as the driver deems it necessary. The pipes running to the springs are carried along the frame side members and those running to the axles branch off from the frame and run along the springs. The pipes are sufficiently flexible so that the relative motion of the different parts of the car will not cause breakage. — Monitor Lubricating Co., 1218 Chestnut Street, Philadelphia, Pa.

Shaler Tube Vulcanizer

This vulcanizer is especially designed for repair shop use, the machine surface of the tube plate which is 4¾ by 24 in. standing 9 in. above the base, adapting it to installation either on the floor or work bench. This vulcanizer, like all Shaler types, embodies the automatic temperature control. The tube clamping device is also new, four clamps being provided, adjustable to any position along the plate, and instantly attachable to a tube. The entire length of the plate may be used for single long repairs or four tubes can be mended as quickly as one. Steam is generated to vulcanizing pressure in 15 min. and is maintained there indefinitely without attention from the operator by means of a thermostatic damper, which regulates the intensity of the flame produced by the gas or the gasoline burner. A steam gage and safety valve are fitted. The vulcanizer sells for $25.—C. A. Shaler Co., Waupun, Wis.



Shaler tube vulcanizer especially designed for repair shop work

Dig-U-Out

This emergency device provides extra traction. A metal paddle is clamped onto each rear tire when the roads are exceptionally bad or the car is stuck, and is said to enable a car to pull out of any mudhole. Price, single-tire size, $10; dual-tire size, $14.—Protex Co., 1790 Broadway, New York City.

Dig-U-Out emergency traction device

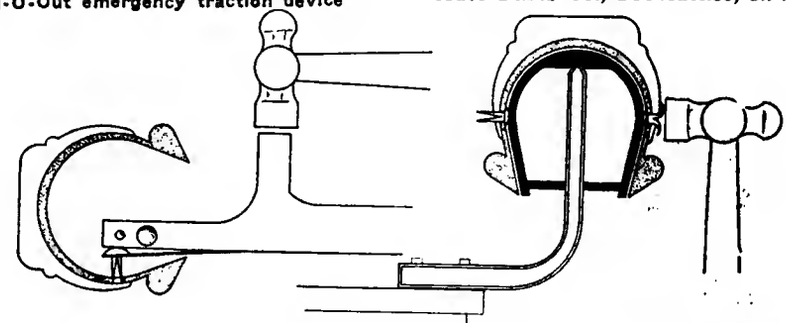
Star Tire Retread Kit

This kit contains the tools necessary to rivet the tread of one old tire over another. It consists of three mandrels, a rivet set, fabric knife, pliers, can of cement, brush and clamp. The bead of one old shoe is removed and its tread is cemented over the tread of another old shoe having a good bead. The mandrels are then employed in driving the rivets from the inside and clinching them securely on the outside of the tread. Price, complete, $8.—Star Auto Supply Co., Spokane, Wash.

Apco Ford Specialties

A set of valve grinding equipment including the Apco valve spring remover which keeps the springs compressed, permitting the use of both hands, a grinding tool that can be easily used on the fourth cylinder and a large box of carborundum grinding abrasive sells for 60 cents.

The company's improved clutch control throws the clutch into neutral when the brake pedal is used. This prevents the engine working against the brake and saves wear on the brake lining. The control is easily attached with a screw driver and wrench in a few minutes, no fitting being required. The manufacturer states that the control is of special value in congested traffic. It sells for 30 cents. —Auto Parts Co., Providence, R. I.



Star kit containing all tools required for riveting the tread of an old tire over another

Industrial Miscellany

Factory

Ajax-Grieb Rubber Co., Trenton, N. J., is building a four-story brick and steel addition to its plant at a cost of about $300,000.

Youngsville Radiator Co., Youngsville, Pa., builder of automobile radiators, will increase its capital stock from $25,000 to $50,000. The company now occupies 8600 sq. ft. of space, but will build probably next spring.

Motor Parts Co., Newcastle, Ind., is building an addition to its plant, 80 by 180 ft.

Reliance Motor & Tool Co., Toronto, Ont., has been formed to make tools and motor appliances. Incorporators are W. B. Sturrup, J. S. Duggan and C. A. St. C. McKay, of Toronto.

Pilot Motor Car Co., Richmond, Ind., has work well under way on its new building, which it expects to occupy in three weeks.

Pull-More Motor Truck Co., New Castle, Pa., has broken ground for the erection of a new plant. The company is capitalized at $800,000 and employs 300.

Boone Tire & Rubber Co. will establish a plant in Sycamore, Ill. It is expected to have tires on the market in February.

G. W. Childers & Co., manufacturers of steel casings for automobile tires, is locating its principal plant in Wichita, Kans.

M. E. Kern has bought land in Allentown, Pa., on which he will erect a plant for the manufacture of motor trucks.

Rogers & Madison Truck Co., Petersburg, Va., is planning the construction of a factory building to cost $15,000.

Westgard Tire & Rubber Co., Warren, Ohio, will shortly begin the erection of the first unit of its new plant, which will be 100 by 240 ft., two stories and basement, and a power plant.

Howell Electric Motors Co., Howell, Mich., has increased its capital to $100,000, and is preparing plans for an addition 40 by 100 ft.

Doehler-Die Casting Co., Brooklyn, has let the contract for a concrete and steel addition to its plant. It will be 50 by 100, seven floors, and will cost about $150,000.

Wright Wrench & Forging Co., Canton, O., has disposed of its entire wrench and small tool business and the name has been changed to American Forge & Machine Co. The plant has been doubled in size and is now devoted exclusively to the manufacture of heavy drawn forgings up to 15 tons in weight and a line of motor car drop forgings. A heat treating plant has been added.

Lycoming Rubber Co., Williamsport, Pa., has started the erection of a large brick addition, 55 by 100 ft.

Marion Metal Products Co., Marion, Ind., has been formed to manufacture automobile accessories. The directors are W. E. Plummer, G. A. H. Shideler, C. A. Williams, G. C. Condo and J. R. Browne.

Dall Motor Parts Co., Vermillion, Ohio, has been formed and will erect a building, 40 by 83 ft., to manufacture pistons and other automobile parts. W. E. Derr is president, and L. A. Dall, general manager.

Cutler-Hammer Mfg. Co., Milwaukee, manufacturing the C-H magnetic gearshift and other electric controlling devices, switches, etc., will start work at once on the erection of a new administration building, laboratory and general industrial building, costing $150,000. Plans have been completed and contracts awarded. The building will be 283 ft. long and 50 ft. wide, six stories and basement, of fireproof construction. It is to be ready about May 1, 1917.

Four Wheel Drive Auto Co., Clintonville, Wis., which has been erecting large additions to its factory all year, is now erecting a solid brick warehouse, 40 by 100 ft. in size, for storing rough castings.

Skilled foundry labor is restricting the desired extension of operations by the Western Malleables Co., Beaver Dam, Wis., which some time ago added a department for the production of castings for the motor car and tractor industry. The company owns three large foundries, two of which are operating at full capacity. One furnace in the third plant was lighted during the last week, but only one or two heats a day can be taken because there are not enough men available to handle the work.

Forschler Motor Truck Manufacturing Co., Inc., New Orleans, made the first display of 1 and 2-ton trucks, built in the plant of the former Forschler Wagon Manufacturing Co., at the National Farm and Live Stock Show here. The company was organized June 6, capitalized at $500,000, and will turn out vehicles steadily. Adolph Dumer, president of the Metropolitan Bank, is president.

Ever-Tight Piston Ring Co., St. Louis, has increased its capital stock to $50,000. R. Koehler is president and treasurer. The company's plant will be enlarged at once.

Yuma Auto & Tractor Co., Yuma, Col., agent for Ford cars and Plowboy, Moline, Bull and International tractors in Yuma County, has built a $14,000 fireproof garage, 60 by 140 ft., two stories, pressed brick.

Auto Radiator & Fender Works, Tacoma, Wash., has purchased machinery for the manufacture of automobile radiators.

Personal

Frank Dawson, for several years manager of the Mogul Truck Co. of St. Louis, has resigned to go to Chicago, where he will be connected with a company that will begin the manufacture of trucks Jan. 1.

H. H. Brooks has been appointed superintendent of agencies for the Madison Motors Co., Anderson, Ind.

W. T. Stalnaker, formerly of the mechanical department of the Pathfinder Co., Indianapolis, has been appointed service manager of this company.

D. B. Ashton, Marion, Ohio, will handle the Cadillac and Chalmers.

R. C. Ridge, former superintendent of the Marathon Tire & Rubber Co., Akron, and at one time connected with the Firestone company, of that city, has succeeded C. F. Piskton as superintendent of the Porter Rubber Co., Salem.

George Muehl has resigned his position as assistant manager of the Cadillac Motor Car Co., Detroit branch, and will associate himself with a concern dealing in investments and bonds.

J. F. Madden has been appointed sales director of the Pacific Coast for the Pennsylvania Rubber Co., and C. F. Kent, of the Rocky Mountain District of the West.

P. G. Sedley has become manager of the direct branch of the Eisemann Magneto Co., Chicago, Ill. He was formerly manager of the New York branch of the Heinze Electric Co., Lowell, Mass. Mr. Sedley will take up his new duties on Jan. 15.

George Tracy has been transferred to the Newark, N. J., office of Clodio & Engs, New York distributer of the Kissel Kar.

R. P. Ford has joined the truck sales organization of the Peerless Motor Car Co., Cleveland. He has been connected with the automobile industry since 1906, at that time with the Overland company.

H. W. Winn is the new sales manager of the Southern Motors Co., Louisville, Ky.

A. E. Ward, formerly sales representative of the Prest-O-Lite Co., New York, has been made division manager.

A. E. Walden has joined the C. T. Silver organization in New York, Chalmers and Dort, where he will have charge of the service and mechanical departments.

F. H. Whitman has been appointed production engineer for the National Motor Vehicle Co., Indianapolis. He was formerly connected with Dodge Brothers.

L. H. de Graaf, Richmond, Va., former manager of the Richmond branch for the Kissel Sales Co., has been made retail sales manager for the Terminal Motor Co., selling Hupmobile and Dort.

Herbert W. Little has been transferred to the Willys-Overland factory, Toledo. Mr. Little was formerly the zone service manager for the company in the New England States. He will be succeeded by F. H. White.

George Cushing has accepted a position with the advertising department of the Hudson Motor Car Co., Detroit. Mr. Cushing was formerly the advertising manager of the Federal Motor Truck Co.

James Coggeshall has been appointed manager of the wholesale department of the R. E. Taylor Co., New York, distributor for Garford trucks in this city, New Jersey and New England.

Dealers

Prest-O-Lite Co., Inc., Milwaukee, has been reorganized. C. F. Mitchell, manager of the Milwaukee branch, 18-20 Martin Street, has been promoted to division manager, with headquarters at Milwaukee. He is succeeded by E. P. Drummond.

Carl M. Green Co., Detroit, has been selected as advertising agent of the Nash Motors Co., Kenosha, Wis.

H. A. L. Motor Sales Co., Milwaukee, has been organized by Charles Gordon to act as distributer of the Hal Twelve in the Wisconsin and upper Michigan territory. Offices have been opened at 424 Wells Building, Milwaukee.

Quaker City Taxi Cab Co., Philadelphia, has placed an order with J. D. Howley, manager of the local White branch, for 100 taxicabs, the largest order placed in this city.

Hearn Tire & Rubber Co., Columbus, Ohio, has been succeeded by the Kelly-Springfield Tire Co., which has established a direct factory branch at the former location, Gay and Fourth Streets.

Chattanooga Saxon Co., Chattanooga, Tenn., recently organized, announces the purchase of the Saxon agency and territorial rights from the Bill Jones Automobile Co. Until salesrooms are leased the new company will retain headquarters with the Bill Jones Co.

All-Year Motor Co., Denver, is the name of a new Kissel distributing agency for Colorado and southern Wyoming. It is located at 1517 Cheyenne Place.

Chandler Motor Co. of Colorado, Denver, Chandler distributer for Colorado and Wyoming, has secured the Stutz distributing agency for the same territory.

Tate-Gillham Motor Co., St. Louis, Dodge agent, has moved to 3107-11 Locust Street.

J. B. Howard Motor Sales Co., St. Louis, will handle the Dixie Flier and the Old Hickory truck in Missouri and Illinois south of Peoria.

Packard Missouri Co., Kansas City, has opened a branch at Wichita, Kan. C. G. Anderson, who formerly sold the Packard in St. Louis and in Kansas City, is in charge of the new branch.

James Barnes, general sales agent for the R. E. Dietz Co., lamp maker, has moved his office from 71 Parkway to 306 and 307 Carter Building, corner Church and State Streets, Rochester, N. Y.

Fisk Rubber Co. has leased a four-story building at 664-66 North Broad Street, Philadelphia.

Goodyear Tire & Rubber Co. will move into a new building in New Orleans, at 818-20 Howard Avenue.

Smith Form-A-Truck Sales Co., Indianapolis, has opened new quarters at 1327 East Washington Street.

Springfield Body Co. has opened a New York service station at 22 West 61st Street. Charles Baasch, formerly located at the factory in Springfield, Mass., is manager of the new service station.

Kokomo Brass Works, Kokomo, is represented by the Prie Sten Sales Co., Chicago.

R. Greenlaw, New Orleans, motor truck dealer, has added the Avery tractor.

Mohawk Rubber Co., Akron, has leased a two-story building in Kansas City at 1928 Grand Avenue.

Michelin Tire Co., Milltown, N. J., has established an agency in Indianapolis.

Mohawk Rubber Co. has established a tire branch in Kansas City at 1928 Grand Avenue. W. J. Smith is in charge.

R. C. Greenlease, president of the Greenlease Motor Co., distributer of the Cadillac in Kansas City territory, has purchased a site 114 by 300 ft., on which a building will be erected for the company in the spring. The site is at Twenty-ninth and McGee Streets.

H. H. Heaps, formerly with the Hiatt-Buick Co. at Kansas City, Mo., has been made local manager of the Reno Buick Co., Hutchinson, Kan. R. R. Rosier has disposed of all his interests in the Hutchinson Buick Co. to the new firm.

Kelly-Springfield Tire Co. has just opened a factory branch in Baltimore, Md. H. H. Grobe, formerly manager of the truck-tire sales at the New York branch, is manager. Carl Spoerer's Sons Co., which formerly handled the Kelly-Springfield line, has taken on the Republic Rubber Co.'s line.

Ross Eight, handled by J. J. McCarthy at Boston, Mass., for the past year, is now represented by the Bishop Motor Car Co.

Connell-McKone Co., Boston, Mass., has opened new salesrooms at Manchester, N. H., where it recently started an Overland branch.

Dodge Brothers opened an agency at Holyoke, Mass., with the P. A. Williams Co., Springfield.

Reo and **Chevrolet** have been placed at Manchester, N. H., with H. C. Lintott.

J. F. Grant has added the Buick to his line at Brockton, Mass.

White Motors Co., New Haven, Conn., is in its new home. It will give the company some 25,000 sq. ft. of floor space. The service department is already in its part of the building. The building is located at 264-266 Crown Street.

M. Bell's Son, Franklin, La., State distributer of the Marmon cars, has opened salesrooms at 536-538 Barronne Street, New Orleans. A. N. Jacobs of Franklin is manager of the new branch.

Goodyear Tire & Rubber Co., New Orleans branch, has moved into a new three-story building at 818-820 Howard Avenue. W. E. Dermondy is manager.

Chase the Winter "Bug-a-boo"

It exists in memory only. It's a thing of the past. The dull-winter-business period of previous years is dead. Let's bury it—then forget it.

Get a new grip on your business. *Believe* as other live dealers *know* that there will be a *big* winter business this year.

More cars will be in use *this winter* than were driven in the summer two years ago. At least 75 per cent of the cars will be in constant service.

This means that there is a *big winter* business for you if you will only go after it.

And don't forget, Stewart Products will sell faster than ever. Each Stewart Product is a real necessity for the car in winter as well as summer.

"It will pay you to see that every car is Stewart equipped."

Hydraulic Steel Co. Refinancing

Plans $10,000,000 Co.—Standard Oil Interests Back of Reorganization

CLEVELAND, OHIO, Nov. 27—The Hydraulic Pressed Steel Co., one of the largest producers of pressed steel wheels, frames and forgings, has a plan under consideration with the Standard Oil Co., which provides for the formation of a $10,000,000 company which will include the Hydraulic company and one other. Under this plan the holders of the Hydraulic common will receive approximately $108 cash for each share plus $162 par in the stock of the new company. By the deal this would mean a withdrawal of part of their investment in cash by sellers of the Hydraulic stock while the balance would remain in the company as now.

The management would undergo virtually no change and the board of directors would include Clevelanders and representatives of the country's leading financial interests. The Hydraulic company would continue to manufacture its present lines, according to the plan, and would enlarge its output.

This company was organized in 1906 and its production has amounted to $7,000,000 yearly.

—

Farr Leaves SKF Bearing Co.

HARTFORD, CONN., Nov. 28—A. V. Farr has become sales manager of the Hess Steel Corp., Baltimore, Md. He was formerly advertising manager of the SKF Ball Bearing Co., this city.

—

Herschell-Spillman Adds New Model

NORTH TONAWANDA, N. Y., Nov. 28—The Herschell-Spillman Co., whose motors now are used in a large number of passenger cars and commercial vehicles, is shortly to bring out a new model. It will be a 3¼ by 5 motor, of L-head design, for commercial vehicle and small car use. The present capacity of the plant is from 15,000 to 20,000 of these motors a year. Details of the new motor are at present being worked out by Designer E. O. Spillman, and it is hoped to have samples ready by Jan. 1.

—

Schoeneck to Make One Chassis

CHICAGO, Nov. 27—The Schoeneck Co., of which J. Alvin is president, will produce one chassis equipped with four body models. These are two, four, six and seven-passenger types. The car is equipped with a 4 by 5½ in. six-cylinder Herschell-Spillman motor, other equipment including a Brown-Lipe four-speed gearset, Brown-Lipe disk clutch and Timken axle. The wheelbase is 139 in. and tires are 34 by 4½.

—

Schaaf with Fisher Tractor Interests

INDIANAPOLIS, Nov. 27—A. R. Schaaf, for many years secretary of the Fiat Automobile Co., Poughkeepsie, N. Y., and previous to that connected with the Pope Mfg. Co., Toledo, Ohio, has united with Carl G. Fisher in the manufacture of a farm tractor and will associate himself with that organization in the capacity of factory manager.

—

Pfeffer to Retire from Chalmers

DETROIT, Nov. 28—C. A. Pfeffer, vice-president and assistant general manager of the Chalmers Motor Co., this city, will retire shortly from that company to enter into business for himself. He will remain, however, as a stockholder and director.

—

Hibbard Is Regal Asst. Sales Mgr.

DETROIT, Nov. 27—V. S. Hibbard has joined the Regal Motor Car Co. as assistant sales manager. Mr. Hibbard was formerly sales and advertising manager of the R. C. H. Corp.

Oct. Truck Exports Smaller

Drop Nearly $2,000,000 in Value—Passenger Cars Gain —Total $9,341,119

		1916			
Mos.	Cars	Value	Trucks	Value	Parts
Oct.	4880	$3,756,768	1144	$3,635,291	$1,949,060
Sept.	3585	2,819,405	1835	5,203,215	2,095,188
		1915			
Oct.	3479	2,749,255	1596	4,307,190	1,819,950

WASHINGTON, D. C., Nov. 27—The feature of the export trade in October was increased exports of passenger cars and parts with a diminution of exports in commercial cars. Figures just announced by the Department of Commerce show that during October last there were 1144 commercial cars, valued at $3,635,291, and 4880 passenger cars, valued at $3,756,768, together with parts to the value of $1,949,060, exported to various foreign countries. For the corresponding month of last year the figures were: Commercial cars, 1596, valued at $4,307,190; passenger cars, 3479, valued at $2,749,255; parts, not including engines and tires, $1,819,950.

During the 10 months of 1916 the figures show that 15,917 commercial cars, valued at $44,006,346, and 51,699 passenger cars, valued at $36,049,497, together with parts, not including engines and tires, to the value of $20,091,793, were shipped abroad. During the same period of last year the commercial car exports numbered 18,865 machines, valued at $52,076,406 and passenger cars to the number of 34,515, valued at $29,543,227. The exports of parts, not including engines and tires, were valued at $12,814,809.

The big buyers in October last were as follows: France, 522 cars, valued at $1,782,088; United Kingdom, 684 cars, valued at $1,687,152; Canada, 1021 cars, valued at $718,962; West Indies and Bermuda, 665 cars, valued at $505,198.

Knickerbocker Co. Reorganized

Larger Output — Capital Is $500,000—To Add Tractors to Truck Line

NEW YORK, Nov. 24—The Knickerbocker Motors, Inc. has been incorporated in this city to take over the Knickerbocker Motor Truck Mfg. Co., which for several years has made trucks in New York City. The new corporation is essentially a reorganization of the old concern on a broader scale and contemplates the production of 500 chassis the first fiscal year.

H. G. Streat, president of the Streat Coal Co. and founder of the Knickerbocker Motor Truck Mfg. Co. is president; A. C. Brady, formerly president of the Brady-Murray Motors Corp., Chandler dealer in New York City is vice-president and sales manager; H. G. Streat, Jr., son of the president, is treasurer; and W. C. Guilder, formerly production manager for the Kelly-Springfield Motor Truck Co., designer of the first Garford trucks and early Macks, and also production man with the Timken-Detroit Axle Co., is production manager.

Mr. Streat, Clarence A. Ludlum, Charles H. Class, W. H. Bonynge and Grove D. Curtis are the directors.

The products will be a 2½-ton truck, a 5½-tonner and a 3-ton tractor. Two hundred of the 2½-tonners, 100 of the 5½-tonners and 200 tractors are expected to make up the first year's production.

The concern has an authorized capital of $500,000, all common, $10 par value per share. In a statement by W. A. Lewis and J. B. Linn, underwriting managers it is stated that $250,000 of this stock will be placed on the market, to be held until it is all paid for, subscribers receiving receipts to be held until it is all subscribed. If, after a reasonable time the stock is not all subscribed, the full amount paid in by subscribers will be returned. It is also stated that none of the capital thus raised will be used for promotion; but will all be devoted to the conduct and expansion of the business.

The concern will occupy the old plant of the Knickerbocker company at 151st Street and River Avenue, Bronx, New York.

—

Race Gillette Tire Sales Manager

EAU CLAIRE, WIS., Nov. 25—C. G. Race, until now general manager of the Chicago branch of the Gillette Safety Tire Co., this city, has assumed the position of general sales manager and a director of the Eau Claire concern. Further, the entrance of eastern capital into the company has caused it to increase its authorized capital from $250,000 to $1,000,000. As soon as possible, the second unit of the new tire and commercial rubber goods plant just completed will be undertaken, and by March 1 or April 1 the capacity will be more than doubled. Within a year it is hoped to increase the output to 1000 tires a day. R. B. Gillette, founder of the concern, continues as general manager.

—

Wilson Adds 1-Ton Model

DETROIT, Nov. 27—Smaller than the 2-ton single chassis upon which the J. C. Wilson Co. of this city has heretofore specialized, but incorporating the same general features of design, a 1-ton model of Wilson truck has just been placed on the market. The new model rounds out the line more than is at first apparent, since with tractors made by shortening the wheelbases of these two models it is possible to embrace practically all load capacities from 1 to 6 tons.

—

Smith Truck-Forming Attachment for All Cars

CHICAGO, Nov. 27—Additional capital brought about through the re-organization of the Smith-Form-A-Truck Co., and the taking over of this concern by the newly formed Smith Motor Truck Corp., is to make possible the extension of this particular truck-forming attachment to cars other than Fords. Already attachments are being made for such cars as Dodge, Maxwell, Buick, Overland and Chevrolet. The new unit for application to other cars will be known as the Universal, although this term does not have its usual meaning since units under this name will not apply to all cars for some time.

Attachments for Maxwell and Chevrolet have a frame of 4-in. channel section, the same as the unit for Fords and they sell at the same price as the Ford attachment or $350. This unit will convert this car into a 1-ton truck, but the larger size, the frame of which will be 5-in. channel section, will be designed for loads of 1500 lb.

Capacity for production of the attachment that has been made for Ford cars for the last 2 years is now 300 a day, and as announced last week, additions to the plant will be built which will practically double the floorspace and thus the company expects to be able within 3 months to take care of any demand that may come for these units either for Fords or other cars. At present the company is making an average of one a day of the Universal attachment, but is unable to keep pace with the demand for this particular unit, dealers in some cities asking for them in carload lots.

The method of attachment for the newer units is the same as for the Ford; that is, the rear axle of the car is used as a jackshaft for chain drive.

Detroit to Be Aviation Center?

Signal Corps, Representing Army and Navy, Visits Detroit and Buffalo

NEW YORK CITY, Nov. 27—The interest of the government in having automobile manufacturers take up the problem of aeroplane manufacture was evidenced last week when the Signal Corps, representing the Army and Navy, visited Detroit, Buffalo, and some other points with the thought of establishing aviation training stations in at least Detroit and Buffalo. The government recognizes that the automobile manufacturers are well qualified to carry out all work of aviation design and manufacture. There is no better manufacturing organization to handle such work and it is for this reason that these two cities are being considered, Detroit because of its leadership as an automobile manufacturing center and Buffalo because of the volume of aeroplane manufacture at present carried on there.

May Buy Joy Field

With this object in view the government is considering the possibility of taking over in Detroit what is known as the Joy Aviation Field, which is the testing ground purchased some time ago by the Packard company. The matter is only under contemplation. Howard Coffin of the Council of National Safety, and also of the Navy Consulting Board, has been making the rounds with the Signal Corps in its investigating work.

—

Stout Is Packard Aircraft Manager

DETROIT, Nov. 24—W. B. Stout has been appointed manager of the aircraft division of the Packard Motor Car Co. Mr. Stout is at present general sales manager and advertising manager of the Scripps-Booth Corp. He will resign his present position on Dec. 2.

—

Brown Becomes Scripps Sales Manager

DETROIT, Nov. 24—W. I. Brown, who has been assistant sales manager of the Scripps-Booth Corp., will become the general sales manager Dec. 1. Mr. Brown joined the Scripps-Booth company after resigning from Dodge Bros.

—

Smith Blair Truck Sales Manager

NEWARK, OHIO, Nov. 24—G. E. Smith has become sales manager of the Blair Motor Truck Co., F. L. Swanberg has resigned as manager. The management of the factory will be in charge of J. P. McCune and F. O. Spaulding.

Two 1917 Studebaker Chassis

Four-Cylinder in Three Body Styles—Six-Cylinder Available in Six

DETROIT, Nov. 28—*Special Telegram*—The program of the Studebaker Corp. for 1917 will include a four-cylinder and six-cylinder chassis. These are known as series 18. Both of these chassis and the bodies are considerably refined and improved in the direction of greater comfort and convenience for the passengers. Fundamentally neither chassis has been altered. Among the important changes are a reversible seat, so that the passenger can face either front or back. Both front seats are adjustable for different leg lengths and on the backs of the front seats there are flexible leather robe straps. The tonneau is roomier because of a new design of auxiliary seats which fold under the rear seat, instead of against the back of the front seat. These new seats are armchairs.

Pistons Are Lighter

In the engine the pistons have been lightened, to some extent reducing vibration, and the oil pump has been re-designed to move a more positive oil feed.

Although the rear axle is quite similar to last year's Timken bearing design, it has been materially strengthened and in the electrical system the characteristics have been altered to give about 12 per cent greater starting torque. There is a new convertible top known as Every-Weather which fits to the touring body, providing a sedan when in place. Better equipment is provided, particularly in the way of Blackmore door curtain openers which permit the side curtains to open with the door; also Yale lock for the ignition switch.

In the four-cylinder model there will be a three-passenger roadster at $930, a seven-passenger touring car at $940 and a three-passenger landau roadster at $1,150.

On the six chassis there will be a three-passenger roadster at $1,170, a seven-passenger touring car at $1,180; a three-passenger landau roadster at $1,350, a seven-passenger touring sedan at $1,700, a four-passenger coupé at $1,750 and a seven-passenger limousine at $2,600.

Charter Oak Six on Market Next Spring

HARTFORD, CONN., Nov. 27—Early spring is the time at which the recently incorporated Eastern Motors, Inc., this city, expects to have the first Charter Oak car on the market.

The Charter Oak is to be an assembled proposition combining a Herschell-Spillman six-cylinder engine, a four-speed Brown-Lipe transmission and Timken axles. It is the desire of the Eastern Motors, Inc., to build the car in Hartford. A canvass of possible sites for a factory have availed little as yet.

Rumor has it that the concern may possibly locate in Waterbury. The sales department announces that dealers have been secured for the first year's output at least. The temporary executive offices and the engineering department are located at 1026 Main Street in the Pilgard building. The major portion of the stock is owned in Waterbury.

Grant Will Move Shortly

DETROIT, Nov. 24—The Grant Motor Corp. of Findlay, Ohio, will move to its new plant in Cleveland within the next two weeks. The company still has 300 cars to finish at Findlay and will start production before Dec. 1 in Cleveland with a schedule for 1,000 cars in December.

General Motors Opens Marquette Plant

DETROIT, Nov. 24—The old Marquette motor plant at Saginaw, Mich., has been opened by the General Motors Corp. to be used as a storage and transfer house this winter. The plant has been opened to facilitate shipment of Buick cars.

E. S. Swift an Overland Director

TOLEDO, OHIO, Nov. 24—E. S. Swift, vice-president of Swift & Co., Chicago, has been elected a director of the Willys-Overland Co.

Autocar Co. Elects Officers

ARDMORE, PA., Nov. 28—E. A. Fitts, formerly secretary and treasurer of the Autocar Co., this city, has been elected vice-president, and F. C. Lewin, formerly assistant secretary and treasurer, has been elected secretary and treasurer. J. C. Taney will take up Mr. Lewin's former duties. The other officers were re-elected, being D. S. Ludlum, president, and L. S. Clarke and W. W. Norton, vice-presidents.

Hoover ¾-Ton Delivery Car

YORK, PA., Nov. 27—A ¾-ton delivery car has been brought out by the Hoover Wagon Co., this city.

The engine is 3¾ by 4½ block cast design, cooled by thermo-syphon circulator through a cellular radiator. Ignition is supplied by a high-tension magneto with hand adjustable spark advance. The clutch is a three-plate design and the gearset has three speeds. Final drive is by shaft and two universals to a worm-driven semi-floating axle. Torque and propulsion being taken by the spring. Both springs are located on the rear wheel drum.

Four Companies To Raise Prices

Velie and McFarlan Cars and Riker and Chase Trucks Increased on Higher Cost

MOLINE, ILL., Nov. 27—The Velie Motors Corp., this city, will advance its prices $50 on the open bodies delivered on and after Jan. 1, 1917. Cars ordered and delivered prior to that date will be at the present prices, which are as follows: Model 28, $1,085 (with detachable sedan top, $1,285); four-passenger roadster, $1,085; two-passenger roadster, $1,065; model 27, $1,550. The closed models are excepted from the advance.

McFarlan Raises Prices $300

CONNERSVILLE, IND., Nov. 24—The McFarlan Motor Co., this city, will raise its prices $300 after Dec. 1. Touring cars and companion models will list at $3,500 and closed work will list from $4,600 to $5,300.

Riker Prices to Be Higher

BRIDGEPORT, CONN., Nov. 24—The Locomobile Co. of America on Dec. 1 will raise the prices of the Riker trucks. The 3-ton truck will sell for $3,600, an increase of $100, and the 4-ton truck will sell for $3,750, also an increase of $100.

Winton Continues Two Sixes

CLEVELAND, OHIO, Nov. 24—The Winton Co., this city, will continue its present models in 1917 without change, Model 33 selling at $2,485 and the 48 at $3,500. The company, however, may make an increase in its prices.

Chase Raises Some Prices

SYRACUSE, N. Y., Nov. 27—On two of the Chase models an increase of $75 in list price has been made. These are the 1-tonner, raised from $1,650 to $1,725, and the 1½-tonner, from $1,950 to $2,025. Other prices remain the same as before.

Start Work on Kelly-Springfield Plant

NEW YORK CITY, Nov. 24—Engineers will start work in the near future on plans for the new plant of the Kelly-Springfield Tire Co. at Cumberland, Md. The plant will cover about 75 acres. Ground will be broken early next spring. The completion of the new plant will mean a minimum increase of 400 per cent of the present capacity of that company.

$50,000,000 Business for Pontiac

Financial Outlook There Bright for 1917—Nine New Car and Parts Cos.

DETROIT, MICH., Nov. 25—A banquet held at Pontiac last Thursday night, promised the city the brightest and most prosperous financial future in its history. There were nine new companies engaged in the manufacture of automobiles and automobile parts represented who promised approximately $50,000,000 worth of business to the city for the coming year.

The Olympian Mfg. Co. employing 300 men with a weekly pay roll of $6,000 estimated $2,000,000 worth of business for 1917. The Oakland-Northway Co., employing between 1000 and 1500 men with a monthly payroll of $65,000 to $100,000, estimates business for the coming year at from $40,000,000 to $50,000,000. The Monroe Motor Co., employing 500 men with a payroll of $9,000 weekly estimates its next year's business at $4,000,000. The American Forging & Socket Co., employing sixty to eighty men, weekly payroll $1,200 to $1,600, estimates $430,000 in 1917. The Michigan Drop Forge Co., employing ninety-seven men, has a weekly payroll of $2,225 and estimates its business for next year at $388,000. The Columbia Truck & Trailer Co., employing fifty men with a weekly payroll of $1,500, makes an estimate of $4,000,000 in 1917. The Markley Handle Co., employing twenty-one men with a weekly payroll of $400, estimates its business for next year at $50,000. The Vanauken Blower Co. will employ from twenty to twenty-five men with a $500 weekly payroll and makes an estimate of $97,500.

Among those who responded to toasts were: R. F. Monroe, president of the Monroe Motor Co.; F. G. Clark of the Columbia Truck & Trailer Co.; R. A. Palmer, president of the Olympian Motors Co., and T. H. McDearmon of the Oakland-Northway Co.

—

Page Buggy Adds to Force

DETROIT, Nov. 24—The Page Bros. Buggy Co., Marshall, Mich., manufacturers of automobile tops, has recently doubled the working force of the organization and is in search of more men. The company is supplying the Briscoe Motor Co. and others with automobile tops.

—

Cole Heads Perfection Tire Co.

CHICAGO, ILL., Nov. 24—C. R. Cole has become president of the new Perfection Tire & Rubber Co. as a result of the recent merger of that company with the Champion Auto Equipment Co., Wabash, Ind., and the Perfection Tire & Motor Co., Niagara Falls, Ont. Arrangements have been made for the transfer of the assets and obligations of each company to the new company, which has taken out a charter under the laws of Delaware. The other officers of the new company are: Vice-president, R. J. Evans; secretary, C. W. Harris and treasurer, E. A. Stickelman. In addition to the officers, the directorate consists of the following: F. E. Humphrey, T. J. Moll, T. W. Cole, and H. M. Scambler.

Outside of the patents, the new company will have tangible assets of nearly $1,000,000 with less than $25,000 of liabilities.

—

Haynes Plans Increased Production

DETROIT, Nov. 24—The Haynes Automobile Co. has made plans for the purchase of machinery for a capacity of 100 cars daily. A new building will be erected with a capacity for three times as many cars as are made at present, and will have 600,000 sq. ft. of floor space. The company has 350,000 sq. ft. at present.

—

New Record for Delco Shipments

DAYTON, OHIO, Nov. 24—All former production records were broken last week in the plant of the Dayton Engineering Laboratories Co., this city. Though no figures were given as to the number of Delco systems shipped during the week, the former record was that ending Oct. 28, when 6836 systems were shipped.

—

Canadian Chevrolet Co. Expands

DETROIT, Nov. 24—Extensions are being made to the present plant of the Chevrolet Motor Co. of Canada, at Oshawa, Ont. The company has been manufacturing cars for a year and disposed of 8000 last year. Three new buildings are in process of erection and will give an added floor space of 277,075 sq. ft.

—

Hilts Enters Advertising Agency

DETROIT, Nov. 28—M. R. Hilts has resigned as advertising manager of the Puritan Machine Co., this city, to enter an advertising agency in Chicago.

—

Vincent Wheel in New Location

DETROIT, MICH., Nov. 24—The Vincent Clear-Room Steering Wheel Co., this city, has moved to 756 Woodward Avenue, the former offices of the Hyatt Roller Bearing Co. This company recently effected a reorganization by which E. H. Vincent became president and general manager; J. A. Martin, vice-president; H. H. Vincent, secretary and treasurer, and G. F. Burger, sales manager.

Detroit Electrics in Quantity

New Model $500 Lower Because of Standardized Design and Greater Production

DETROIT, Nov. 27—An entirely new Detroit electric has been brought out by the Anderson Electric Car Co., this city. The new model, known as 68, represents the initiation of a production policy for Detroit electrics. As a result of a greater increased production schedule the model 68 will sell for $500 less than its predecessor. This cut from $2,275 to $1,775 in the face of greater increased cost of materials represents the saving due to the installation of a large amount of labor-saving machinery and the adoption of a standardized chassis in which the number of options has been minimized so far as color and equipment is concerned. For instance, in upholstery there are three designs to choose from, while in painting there is one standard, whereas last year there was an unlimited field for either upholstery or painting. No sacrifice in material or workmanship has been made in any part in quoting the new figure.

The body is a brougham having a passenger capacity of four and is built on a chassis of 100 in. wheelbase with 56 in. tread. It has the standard Anderson motor with forty-two cells, thirteen-plate battery, giving a speed of 6 to 25 m.p.h. and a mileage of 75 to 100 on a battery charge.

100 Per Cent Business Gain

Officials of the Anderson company estimate at the present rate of increase the company's current year's business in electric passenger cars will exceed last year's by at least 100 per cent. The raw material for building the coming year's product has either been delivered to the plant or is under contract for specified delivery dates. The production of Detroit electric cars increased in 1916 over 1915 by 141 per cent, while the labor increase was not 100 per cent. This ratio is due to the introduction of a large amount of new machinery.

The first 4 months of this fiscal year show an increase of 79 per cent over last year.

The company has just erected in Detroit a new four-story service building of brick which has a capacity of 400 cars with repair and charging facilities and a large show and sales room.

—

Dort Director of Guaranty Securities

DETROIT, Nov. 27—J. D. Dort, president of the Dort Motor Car Co., has been made a director of the Guaranty Securities Corp. of New York.

Parcel Post to S. A. Wrong

U. S. Accessory Makers Making Serious Error by Shipping Goods That Way

BUENOS AIRES, ARGENTINA, Oct. 31—U. S. A. accessory manufacturers are making a serious error by sending accessories by parcel post to automobile dealers in Argentina. While the parcel post service is entirely satisfactory for such trade in the U. S. A. it does not work out satisfactorily here; in fact it is the most unsatisfactory way of sending small accessory parts to this country.

Recently a large dealer in Rosario had a typical experience with parcel post. An anti-glare equipment for headlights was sent from a U. S. A. maker and here is the chain of troubles the Rosario dealer had to solve:

"A few days after the anti-glare devices arrived I received an official card without stamp. I presented this at the post office which is only open from 10 to 12, that is that particular section of it. I was asked to call the next day and fortunately found the right man in. I presented the official card and was politely asked to go four doors away to get twelve centavo stamps on it (a centavo is approximately ½ cent, U. S. A. currency). On my return with this they looked a long time to find cards that had come with the parcels. I was sent with these cards to another place where I had to purchase sixty-nine centavo stamps, costing 35 cents. On my return with these and after waiting half an hour I tried to get the package but instead was sent to the custom house.

Ransoming the Package

"At the custom house the real stamping act work begun and for each parcel I had to put a pesos (44 cents) stamp. I required two of these, or 88 cents. With these duties the cost of the anti-glare device was just five times what it sells for in the U. S. A. In addition I had spent nearly a week getting the parcel post package through the post office and custom house.

"After all this trouble I asked what I had been paying for and the chief of the department advised me that the parcel post of the United States is a one-sided affair, and while they send any parcel away from the U. S. A. at regular rates yet in Argentina they charge duties and customs as they wish. The United States should get real parcel post service as far as Argentina is concerned. For reasons I cannot explain parcel post packages from Europe enter Argentina free. When asking why this is, the only answer you get is that if anything is wrong the U. S. A. is at fault. It is pretty hard to buy U. S. A. accessories here and pay exorbitant duties while European goods come in free. It is a subject which U. S. A. accessory manufacturers should consider.

"Now that U. S. A. cars are selling in good quantities through Argentina it is imperative to have accessories for them. Naturally parcel post is one of the simple ways of handling this work and it should be worth while to get parcel post service for Argentina on the same basis as that from England."

Troubles With Shipments

This is only one of the many difficulties the South American automobile dealer has to put up with in connection with shipments from the U. S. A. Recently a large accessory dealer from Cordoba, a city in the interior of Argentina, was required to make a night's trip by railroad from Cordoba to Buenos Aires because of custom difficulties in connection with U. S. A. shipments. The dealer makes a specialty of U. S. A. accessories, but has constant troubles with shipments. On the occasion in question the New York shipper had not made his shipping documents correspond with packages sent. The shipping document showed five packages or crates but there were only four in the custom house. An examination disclosed the fact that the shipping department had combined two of the crates without making the necessary corrections on the document. This resulted in a cost of nearly $70 U. S. A. gold to the Cordoba dealer.

Recently a Buenos Aires dealer in hardware and automobile accessories cited another glaring example of the treatment Argentine merchants are being given at the hands of U. S. A. makers. The dealer here ordered $400 (U. S. A. gold) worth of certain hardware. It was necessary to pay cash with order in order to be assured of reasonably prompt delivery. This order was placed in August, 1915, practically a year ago. In September, 1916, the shipment had not arrived. It arrived a few weeks ago. The U. S. A. manufacturer had the use of the money for a whole year. During that time numerous excuses for delayed delivery had been made. When the order was placed in 1915 there was a great shortage of this kind of hardware in Buenos Aires and the dealer would have had a good ready market. Now conditions have changed. Other supplies have arrived and the market is lower. It is almost impossible in the face of such treatment to see any possibility of U. S. A. firms holding Argentine trade after the present war unless it is that European countries are not financially able to come back and give the market service which they gave before the opening of the war in July, 1914.

Shippers Must Remove Freight

Given 10 Days or Goods Will Be Removed and Stored at Their Risk

NEW YORK, Nov. 28—The freight car shortages has become so serious as a result of the big tieup of cars being used on tracks other than their own, that immediate steps have been taken by the railroads to relieve this condition. All of the railroads of the country have been notified to return to their home lines as soon as possible all cars not their own, especially those used for perishable freight. All shippers and receivers have been notified that freight left on cars for 10 days will be summarily removed by the railroads and the shipment stored at the shipper's or consignee's risk.

Freightage has become so heavy on the smaller railroad lines, that they have been forced to borrow cars from the larger lines, thus curtailing their use on larger lines where they are badly needed at the present time. For instance, one line running out of Detroit bought 9000 cars last year. Less than one-third of these are now in use on its tracks.

With the exception of Fords, which are shipped in parts to assembly plants, all automobiles are being shipped in special cars, either with end doors or very wide side doors. When these cars are diverted to other traffic, the rest of the box cars become useless. Some of the automobile factories have been taking long chances by shipping their products in flat cars over which they constructed temporary tops and in coal cars covered with tarpaulins.

Car Makers Unable to Ship

DETROIT, Nov. 25—More than $4,000,000 worth of automobiles are awaiting freight cars to carry them to their destinations. The shortage has become so severe that manufacturers are seeking storage space so that they can manufacture far enough ahead to care for future business.

Goodrich Accessory Assn. Changes Name

PHILADELPHIA, Nov. 27—The Goodrich Accessory Association of Philadelphia, manufacturer of the Goodrich lock and switch for Fords, license brackets, truss rods, ignition assemblies, and brake shoes for Fords, has changed its name to the Goodrich-Lenhart Mfg. Co., with offices in the Widener Building as heretofore.

The officers of the company remain the same, Ivan Goodrich is acting president and manager of sales, and Mr. Lenhart will continue in active charge of the factory in Hamburg, Pa.

S. A. E. Testing System Proved

Specifications for Acceleration and Economy Tried Out Successfully

NEW YORK, Nov. 21—Yesterday and to-day the research division of the S. A. E. standards committee tried out their recommended standard form for economy and acceleration testing, using the Sheepshead Bay speedway for the trial. It was desired to ascertain if the committee's recommendations were entirely practical, which proved to be the case. Cars for the test were lent by the Marmon company and the Packard company and members of the New York staffs of these firms assisted the members of the committee.

For the acceleration tests records were made on rolls of paper, marks being made as the car reached successive distances equally spaced. In one system there were switches set on the track 100 ft. apart, these being set by a device attached to the front axle, and in this case the recording drum with the paper was stationary. In the other the track switches were replaced by a commutator attached to the front wheel of the car, which made contact once during each turn of the wheel, the recording drum being carried on the car.

In comparing the two methods it would appear that the stationary apparatus is more convenient for a series of tests on different cars, while that mounted in the car itself is a little more flexible for use on the one car. The record of the former is more compact and easier to use for plotting, because there are a smaller number of indications of distance, and these are in even figures. With the latter, acceleration runs are not limited in length, and can be made at any convenient place. There was some discussion as to the accuracy of measuring distance by the front wheel but it was found that two measurements, one at high speed and the other at low speed, checked accurately within the limits of personal error. The slight apparent difference was that the wheel made two more revolutions at high speed than at low speed over the same distance. There is still some question as to the accuracy of a chronometer carried on a car moving at high speed. A series of apparently perfect records was obtained by both methods, in a number of instances records being made by both devices on the same car during the same run.

Each of the cars was given a series of runs for fuel economy, one covering 4 miles at speeds of 6.9, 11.9, 21.5, 27.5, 40, 53.5, 63 m.p.h., and the other being given a similar series of runs at speeds of 9, 19.5, 29.5, 44, 57 and 63 m.p.h. As this was in no sense a regular test of the cars, they were run part of the time with tops down instead of up as called for in the tentative recommendation of the division. Also as the time devoted to the fuel-economy runs was limited, the lengths of different runs were cut down from the specific distance of 10 miles at each of the various speeds except the lowest, which is to be of sufficient length to consume at least 2 lb. of fuel, making complete circuits of the course.

The method used for measuring the fuel is to have two small tanks mounted on the windshield. One of the tanks is arranged for easy detachment so that it can be weighed before and after each run. Both are connected to the carbureter after the regular gasoline pipe is disconnected. The shut-off cocks from the two tanks are interconnected so that the same motion shuts one cock and opens the other.

The tank containing the unweighed fuel is used for manipulating the car and driving before each run at the same speed at which the run is to be made, in order to get the car to the temperature prevailing during the run. As the starting line is crossed the change is made from the unweighed tank to the weighed one, and vice versa at the finish line.

—

New Madison Four-Passenger Roadster

ANDERSON, IND., Nov. 27—The Madison Motors Corp. is placing on the market a new four-passenger roadster on its 120-in. chassis. It is equipped with a 3⅛ by 5 in. Rutenbur engine, and lists at $1,150. The finish is mouse-gray, with red wheels and black fenders.

—

Remodel Aeroplane Factory

DETROIT, Nov. 25—The Williams Aeroplane factory at Fenton, Mich., has been remodeled and made ready for new machinery.

—

Ontario Registrations

WALKERVILLE, ONT., Nov. 24—The province of Ontario leads the other Canadian provinces with 36,300 registrations. Saskatchewan is next with 11,966; British Columbia, third with 9100. There are about 120,000 cars in the whole of Canada, of which 100,363 are Fords.

Toronto leads with 8815 cars as compared with 7367 in 1915. Montreal is second with 3917; Vancouver, third with 3688; and Winnipeg fourth with 3688.

—

254,000 Ohio 1917 Registrations

COLUMBUS, OHIO, Nov. 25—So far 254,000 registrations for 1917 for automobiles have been issued in Ohio. That number includes gasoline and electric car owners as well as dealers and manufacturers.

S. A. E. Sections Are Active

Truck Division of Standards Committee Meets—Detroit Banquet Dec. 15

NEW YORK, Nov. 28—A meeting of the truck standards division of the Society of Automobile Engineers was held in Detroit yesterday, for the consideration of military truck specifications. General progress in the consideration of the subject was made. H. D. Church of the Packard company presided, and General Manager Coker Clarkson attended.

At the next meeting of the Indiana Section, S. A. E., Dec. 15, the subject for consideration will be carbureters and manifolds.

The Cleveland Section S. A. E. at its meeting Dec. 15 will have a paper by J. B. Replogle on how car manufacturers can co-operate with manufacturers of electrical apparatus, such as starting, lighting and ignition. Mr. Replogle is research engineer of the Remy Electric Co.

The Mid-West Section will hold its December meeting on Friday the eighth at Chicago, when Prof. Roach of Armour Institute will outline a new method of test for gasoline engines.

At the meeting of the Metropolitan Section S. A. E. New York, Dec. 21, Elmer Sperry, inventor of the gyroscope and authority on aviation engineering, will speak on the military aspect of aviation possibilities in America.

The Detroit Section, S. A. E., has decided that its annual banquet to the automobile industry will be held at 7 o'clock on Friday evening, Dec. 15, at the Ponchartrain Hotel. This will be the second dinner of the kind by this section, the one a year ago marking the start of the movement.

—

Belgian Automobile Engineers in Detroit

DETROIT, Nov. 28—P. E. Kellecom and J. R. Perrier, engineers of the Fabrique National des Armes de Guerre of Belgium, are in this city investigating the automobile production. They state that the European countries plan to enter immediate quantity production at the end of the war.

—

Cadillac Builds New Sales Structure

DETROIT, Nov. 27—The Cadillac Motor Car Co. will erect a seven-story structure on the site of several temporary buildings, and will use it exclusively for retail sales and service. The building will contain 154,000 sq. ft. of floor space and will have a special feature of a reception room for the service department that will measure 65 by 116 ft., with a domed ceiling 29 ft. high.

Want Higher Fees for Trucks

Commissions Appointed by N. Y. and N. J. Seek Basis Covering Wear on Roads

NEW YORK, Nov. 27—Commissions have been appointed in this State and in New Jersey to determine an equitable basis for increasing the motor truck registration fees. This action is due to the depreciation of the roads in these States, a large measure of which, it is claimed, is caused by the increasing use of motor trucks. The work of the New York commission applies only to the State roads, and, since only about one-fifth of the trucks in the State are driven over these roads, the problem of arriving at a just determination as to how trucks shall pay in proportion to their use of these highways is very difficult. The task of the New Jersey commission is no easier, due to the practical impossibility of increasing the fees of the vehicles responsible for the wear on the roads without discriminatory taxation.

Of National Importance

Any action taken in New York and New Jersey in increasing registration fees for motor trucks will have a wide influence on the procedure in other States throughout the country, so the matter is of national importance.

The New York State Commission, composed of the State engineer, the commissioner of public works and the highway engineer held its first public hearing at Albany Nov. 21. This commission has not yet promulgated any new proposed schedule, so that the first hearing before it resulted in the giving of suggestion. Among the most important of these was the fact that roads should be classed as governmental or State institutions, benefiting alike those who use them as well as those maintaining plants in the area served or those who own real estate in the same territory.

It was pointed out that any law passed basing fees upon the extent of use and wear and tear of roads should include all forms of vehicles, including horse wagons, as well as automobiles and motor trucks. If motor trucks are taxed and not the other types, such a provision would be unconstitutional because of its discriminatory nature.

The impossibility of living up to the word of the New York State law which specifically provides that the new schedule of fees be based upon the extent of use and amount of wear and tear, was brought out by the fact that any such determination along scientific lines would require a tremendous amount of experimentation of various kinds of vehicles operating over various classes of roads at various times of the year.

It was pointed out that upon principle all vehicles should be charged a certain fee to cover registration for identification only and that any additional tax to help pay for the cost of construction and maintenance of the roads should be placed upon all vehicles.

The New Jersey State Commission, which is formed of the engineers of the various counties, acting under the supervision of the State Commissioner of Motor Vehicles is seeking to preserve the present roads until such time as new roads can be built to carry the vastly increased amount of traffic now passing through the State. This Commission, like the one in New York, has its powers limited to the taxation of the motor truck alone and it cannot decide upon any similar tax for horse vehicles.

—

Geronimo Plant for Enid, Okla.

ENID, OKLA., Nov. 25—The Geronimo Motor Car Co. has been organized to manufacture automobiles in this city in a three-story plant. It will produce a six-cylinder car with a Continental motor. The directorate consists of mostly local bankers, and the capital is $500,000. Shands & Funnel are the fiscal agents for the company.

W. C. Allen is president, G. E. Darland is secretary and treasurer and Walter Krouse is vice-president. F. B. Buzzard is a director.

—

Overland Opens N. Y. Salesroom

NEW YORK, Nov. 28—The Willys-Overland Co. to-day opened its new retail sales and display rooms on Broadway and Fiftieth Street. This building is three stories and has a frontage on Broadway of 100 ft.

—

Local Shows

NEW ORLEANS, Nov. 27—The success of the automobile displays at the National Farm and Live Stock Show here has caused much talk among dealers for a concerted effort toward making this exhibition the occasion of an automobile show. The eight dealers who have displays there are telling of sales made and of many prospects obtained. The reason for the limited number of displays was that the managers of the show proposed a tent exhibit, but later consented to place the automobiles in the Manufacturers' Hall. The dealers hope by beginning in time to arrange for suitable quarters next year.

—

Worcester Show a Success

WORCESTER, MASS., Nov. 25—The second annual show of the Worcester Automobile Dealers Assn. ended here to-night and it proved to be a bigger success than the men anticipated.

U. S. Wheel Corp. Is Organized

New Concern Will Manufacture Baker Pressed Steel Wheel—Production Starts Jan. 1

CHICAGO, Nov. 28—The U. S. Wheel Corp. is a new organization formed for the purpose of manufacturing the Baker pressed steel wheel for automobiles, motor trucks, tractors, etc. This concern is an outcome of the Baker Wheel & Rim Co., of this city, a $5,000 corporation organized for the development of the Baker wheel. The U. S. Wheel Corp., which has absorbed the Baker Wheel & Rim Co., will have a large capitalization. Factory location has not yet been decided upon and at the start production will be by having the most of the work done by pressed steel specialists. Production will be started soon after Jan. 1.

Spokes Under Tension

The Baker pressed steel wheel is a flat-spoke type with spokes arranged bicycle-wheel fashion and held under tension. The wheel is stamped from an original circular piece of steel. It is first converted into a plate-shaped stamping resembling a large brake drum which would be the diameter of the wheel. By a further stamping process the spokes are formed. Alternate spokes attach to opposite ends of the hubs, giving two circles of spokes. The wheel is of approximately the same weight as an artillery wood wheel for motor cars. At present two of the large automobile makers are testing the wheel and others are arranging to test it.

The U. S. Wheel Corp. will have for its president, Chas. G. Hawley, a Chicago man representing financial interests. Jos. A. Anglada, consulting engineer of New York City, will be vice-president. For 3 years Mr. Anglada was chairman of the Metropolitan Section S. A. E. Erle K. Baker, inventor of the wheel, will be secretary. Mr. Baker is best known as the inventor of the Baker split rim, which is now used exclusively by the General Motors. Mr. Anglada will move to Chicago to devote his entire work to the organization.

—

Reo Makes Additions to Factory

LANSING, MICH., Nov. 27—The Reo Motor Car Co. is adding two large buildings to its plant. The larger will be 76 by 528, and will be used as a machine shop, and the smaller will be 95 by 224 and will be occupied for heat-treating purposes. The company is also completing a garage and a clubhouse for its employees.

Studebaker Holds Conference

225 Officials Attend South Bend and Detroit Meeting —Interesting Addresses

SOUTH BEND, IND., Nov. 27—More than 225 officials, branch managers, blockmen and dealers connected with the Studebaker sales department, were entertained Wednesday at the annual conference. The program which started in South Bend was concluded Thursday and Friday at the Detroit factory, followed by private conferences with branch managers and blockmen on Saturday. The yearly conference is a sort of debutante party for the new model car, which is brought out about this time.

Four Addresses

Four addresses were delivered at the meeting Wednesday morning in the administration building. The welcome was delivered by F. S. Fish, chairman of the board, who was followed by President A. R. Erskine, giving a resume of the year's work. J. M. Studebaker followed Mr. Erskine, with a talk on "Sixty-four Years of Business Administration." L. J. Ollier spoke at length on the sales policy for 1917. He stated that the corporation did a larger business last year than ever before and that they expected to exceed all previous sales records in 1917.

Speeches at Detroit

Addresses at Detroit were made by R. T. Hodgkins, general sales manager, C. C. Hanch, treasurer, H. T. Myers, commercial car manager and G. L. Willman, assistant sales manager and advertising manager.

L. Markle, the Chicago Studebaker representative, to-day, told of the Studebaker systematic service plan of caring for the car after it is sold, C. N. Weaver, of San Francisco discussed "Exclusive Representation," and E. R. Benson, Portland, Me. presented the dealer's view of Studebaker methods.

The convention closed to-day, with a banquet at the Detroit Athletic Club. L. J. Ollier, vice-president, presided as toast-master.

Special Train for Overland Convention

ST. LOUIS, Nov. 27.—T. L. Hausmann of the Overland Automobile Co. of St. Louis has completed arrangements for a special train to leave here the night of Dec. 10 to take 150 persons to Toledo for the annual Overland convention. The train will be of fifteen sleepers and the delegation will include the local sales force and nearby dealers.

Electric Auto-Lite Service Meeting

TOLEDO, OHIO, Nov. 27—The Electric Auto-Lite Co., this city, will hold a meeting for its service representatives at the factory Dec. 4 and 5, at which it is expected that more than seventy-five will be in attendance.

Bennett Perfecting Distribution Plan

DETROIT, Nov. 24—O. G. Bennett, who resigned from the presidency of the General Export Co., is developing a new automobile distribution plan.

Moon Ships to Porto Rico

ST. LOUIS, MO., Nov. 27—The Moon Motor Car Co. has made a shipment of twenty-five cars to Santiago A. Panzardi of San Juan, Porto Rico, which has taken fifty-five cars from this company since May. The company has agencies in Cuba and formerly sold French and other European cars.

Decker Top Increases Capital

DETROIT, Nov. 24—The Decker Auto Top Co. has increased its capital from $15,000 to $50,000.

Gary Truck Capital Doubled

SOUTH BEND, IND., Nov. 27—The Gary Motor Truck Co., Gary, Ind., has increased its capital stock from $25,000 to $50,000.

Materials Market Steady

Copper, Steel and Lead Slightly Higher—Rubber and Oils Little Changed

NEW YORK, Nov. 27—Prices on automobile materials last week were exceedingly steady, despite the scarcity of these products and the large demand for them. Copper, which has been uppermost in the skyward activities of the metals, has risen 2 cents more a pound to 35 cents. Beams and channels, after quite a steady period, have taken a turn upward, rising to $3.17 per 100 lb., a net gain of 20 cents for the week. Lead prices, always fluctuating, reached $7.30 per 100 lb. on Thursday, holding at that price through to Saturday.

Rubber and the oils have been unusually steady, with few price changes. Shipments of rubber have been coming in regularly from Ceylon. Para rubber seems to have steadied down to normal prices after a period of unsteadiness on account of conditions on the Amazon River.

Standard Parts Stock Issue

CLEVELAND, OHIO, Nov. 25—The Maynard H. Murch Co., investment broker,, is offering a new issue of 7 per cent cumulative tax free preferred stock of the Standard Parts Co., the consolidation of the Perfection Spring Co. and the Standard Welding Co. Par is $100 a share and the dividend periods are March, June, September and December. Of the authorized capital of $10,000,000 preferred, $5,000,000 is to be issued and of the authorized issue of $25,000,000 common only $8,000,000 is to be issued at this time.

White Wants Tax Reduction

CLEVELAND, Nov. 24—County Auditor Zangerle added $5,000,000 to the White company's statement, claiming this to be good will. The company asks for a reduction of valuation amounting to $13,071,000, which the auditor has refused to make.

Metz Makes Welfare Improvements

WALTHAM, MASS., Nov. 24—The Metz Co., this city, has formulated plans for the social benefit of its employees. A clubhouse, athletic field and the freedom to a tract of 147 acres of land are included under the new welfare policy. There is also in contemplation a gymnasium, a separate baseball field, and ½-mile track, which will probably be built in the spring. An adjoining building to the executive and sales force

offices, is now being converted into an engineers' club.

Production at the plant has been increased 40 per cent, and now the capacity is more than 100 cars a day.

—

Bonus for Westinghouse Employees

PITTSBURGH, PA., Nov. 24—Employees of the Westinghouse Electric & Mfg. Co., this city, have been granted an extension of their present bonus system which is to include salaried and office employees on hourly rates, by which they will receive a bonus of 8 per cent of their salary each month, providing their total excusable time absent and late during the month does not exceed 6 hr. incurred on not over three occasions.

An additional 4 per cent will be given each month to employees who have not lost any time from work during the month through absence or tardiness.

—

Automobile Lock Co. Incorporates

GRAND RAPIDS, MICH., Nov. 24—The S. & S. Auto Lock Co. has been incorporated for $20,000. Incorporators are E. W. Slausson, W. B. Brown and A. M. Freeland.

—

Disbrow Motors Co. Organized

CLEVELAND, Nov. 24—The Disbrow Motors Co. has been organized with a capitalization of $25,000. Incorporators are Louis Disbrow, W. D. Callinan, M. Becker, M. L. Fisher and A. B. Crowell.

Automobile Issues Fluctuate

—

Lower Than Last Week—General Motors and Chevrolet Lead Decline

NEW YORK CITY, Nov. 27—Automobile and accessory issues on Saturday closed lower though stronger than on the previous Saturday. There has been a lot of covering in the motor shares during the last few days. Their position had grown strong during the early part of the week as a result of too much enthusiasm on the short side. Motor issues, it seems, are usually in fair demand when other industrials are depressed, and vice versa.

Chalmers and General Motors were the features last week. Chalmers rose 4 points on its common and General Motors dropped 90 points after a similar gain in the previous week. Chalmers held strong despite the publicity given the stock on account of the short selling of its underwriting syndicate. Threats have been made that the handling of the stock would be brought to the attention of the governors of the stock exchange, but this did not affect the issue one way or the other.

The automobile and accessory issues have been on a down market for some time, but it is expected that as soon as the short sellers have their run, prices in general will rise to and above their old marks. Last week Chevrolet dropped 4 points to 172; Peerless dropped 2 points. A few gains were made, however, led by Chalmers, Chandler, Miller, Packard, Regal and Overland. Chalmers rose 4 points on its common; Chandler rose 4 points; Miller Rubber rose 5 points; Packard preferred rose 7 points; Regal, 5 points and Overland 5-8 points on its common and 3⅛ on its preferred.

—

Barley Increases Wages

STREATOR, ILL., Nov. 27—The Barley Mfg. Co., Streator, Ill., maker of the Roamer and the Halladay, announced an increase in wages, or rather the operation of the plant on an 8-hr. basis with 10-hr. pay. In addition, there will be a bonus for the senior employees, etc.

—

Dividends Declared

Stutz Motor Car Co. of America, $1.25-100 per share, payable Jan. 2, 1917, to stock of Dec. 15. Mitchell Motors Co., $1.50 per share to stock of record of Nov. 10, payable Nov. 24.

Morgan & Wright, coupon due Dec. 1 upon 5 per cent gold debentures is payable upon presentation at the Industrial Trust Co., Providence, R. I., or the Chase National Bank, New York.

Texas Co., $2.50 per share on outstanding capital stock, payable Dec. 31 to stock of record Nov. 29.

C. M. Hall Lamp Co., quarterly of 2 per cent.

Packard Motor Car Co., quarterly of 1¾ per cent, payable Dec. 15.

$14,000,000 Dealer Merger

Aaron De Roy Co. Combines with Studebaker Sales Co. of Ohio—Contract Enlarged

DETROIT, Nov. 27—The Aaron De Roy Motor Car Co., distributer of Studebaker cars for Pittsburgh and western Pennsylvania, has merged with the Studebaker Sales Co. of Ohio. The Studebaker Sales Co. was incorporated in September and combined the Blevins Auto Sales Co. of Toledo and the A. R. Davis Motor Co. of Cleveland, so that the new merger includes three of the largest Studebaker distributers. The original contract between the Studebaker Corp. and the Studebaker Sales Co. called for $12,000,000 worth of cars. With the new merger the contract has been changed to $14,000,000, and is the largest single contract made in the history of the industry.

—

Baker Takes Atlantic and Horner

BOSTON, Nov. 25—Day Baker, one of the pioneers of the electric field in New England, who resigned recently as an executive of the General Vehicle Co. at New York, has taken on the Atlantic electric and the Horner gasoline trucks for New England.

—

Leavitt Will Handle Columbia

DETROIT, Nov. 25—J. W. Leavitt will handle the Columbia car for the Pacific coast and is making his preliminary plans for a large campaign.

—

Westinghouse Makes A.B.C. Starter Contract

DETROIT, Nov. 25—The Westinghouse Electric Co. has closed a contract for $250,000 worth of electrical supplies with the A.B.C. Starter Co.

—

Auto Specialties Gets Overland Contract

DETROIT, Nov. 24—The Willys-Overland Co. has contracted with the Auto Specialties Co., St. Joseph, Mich., for 300,000 Bair automobile top holders.

—

Kline in New York

NEW YORK, Nov. 27—The Kline Car is now handled in this city by the W. S. Roberts Motor Corp., 1838 Broadway, at Sixtieth Street.

—

Hassler Motor Co. Formed

INDIANAPOLIS, Nov. 27—The Hassler Motor Co., this city, has been incorporated with a capitalization of $200,000, the incorporation papers stating that the company will manufacture automobiles. R. H. Hassler, head of Robert H. Hassler, Inc., manufacturer of automobile parts, who heads the new company, declined to make any announcement of the company's plans, stating that the plans would be announced in the near future. The incorporators, in addition to Mr. Hassler, are E. D. Fouts and D. G. Ong.

—

Gillam Increases Capital to $800,000

DETROIT, Nov. 28—The Gillam Mfg. Co. has voted to increase its capital stock from $350,000 to $800,000. An issue of $225,000 7 per cent cumulative preferred stock was authorized and has already been subscribed for by present stockholders and others. The company will erect a building for malleable iron manufacture and one for semi-steel work to meet the increasing demand for its products.

—

Wright Adapter Now Western

SEATTLE, WASH., Nov. 27—An agreement has been reached by the Wright Truck Attachment Co. and the Truck Attachment Co., both manufacturing Ford truck adapters under the name Wright, under which the former concern becomes the Western Truck Attachment Co. and its product the Western attachment.

—

Acme Truck Maker to Add

CADILLAC, MICH., Nov. 27—The Cadillac Auto Truck Co., this city, maker of the Acme 1 and 2 ton trucks, will soon add to its factory a new concrete, steel and brick building 96 by 176 ft. The new 3½-ton model is well under way.

—

Universal to Organize Subsidiaries

DETROIT, Nov. 27—The Universal Valveless Four Cycle Motor Co. will move from Grand Rapids to Muskegon, establishing a plant there, with C. E. Johnson president, and will organize subsidiary companies to manufacture its motor. The parent company will have a capitalization of $250,000.

—

New Era Increases Factory

DETROIT, Nov. 24—The New Era Spring & Specialty Co. has increased its productive facilities at Grand Rapids by the purchase of the Ruskin Biscuit plant, which is to be remodeled immediately. The company will maintain its main salesrooms at Detroit.

—

Trucks Carry U. S. Munitions

EL PASO, TEX., Nov. 27—Motor trucks transported the trainload of shrapnel and cannon shells recently received here to Colonia Dublan, the advanced base. There were twenty-seven box cars of ammunition, containing 67,500 shells, packed four to a case.

Kemco Starter Under Hood

Type of Mounting on Ford Crankshaft in Front of Radiator Abandoned

NEW YORK, Nov. 28—The Kemco Electric Mfg. Co., Cleveland, has changed its starting motor for Ford cars so that it will be located under the hood instead of on the crankshaft in front of the radiator, as heretofore. The construction of the motor has undergone no decisive change, although it is somewhat smaller and lighter. It will be installed at the right of the engine and bolted firmly to a casting which takes the place of the front plate on the Ford engine, this casting also being employed as a bracket for the generator. The drive will be by sprockets and roller chain direct to the crankshaft. The fan-type generator will remain unchanged with the exception of its connection with the starting motor, the drive being direct to the crankshaft instead of through the jackshaft assembly.

—

Chevrolet 6000 Cars Behind Orders

DETROIT, Nov. 27—The Chevrolet Motor Co. will close November 6000 cars behind on deliveries on the month's business alone. The scheduled output for December is 10,000 cars. The company reports an export business that will probably amount to 10,000 cars for 1916.

—

Taylor Timken Advertising Manager

DETROIT, Nov. 28—W. H. Taylor has been appointed advertising manager of the Timken Roller Bearing Co., this city. Mr. Taylor was formerly with the Campbell Ewald Co. advertising agency in this city.

—

Chain of Disco Branches

DETROIT, Nov. 28—The Disco Starter Co. shortly will establish a chain of branches in the larger cities by way of facilitating the administration of service to owners. The first branches will be located in New York and Chicago.

—

New Champion Delivery Chassis

CHICAGO, Nov. 27—To manufacture ½- and ¾-ton delivery chassis the Champion Motors Co. has been formed by Cleveland interests in Fulton, Ill. The vehicles will have electric starting and lighting, bumpers, side curtains and other detail refinements. They will sell for from $750 to $775.

The plans of the company were first made public last Saturday, when ten of the new chassis were paraded down the

main streets of Fulton to arouse public enthusiasm.

W. L. Widlar, N. R. Wildman and William Greif head the concern, which has a capital of $5,000,000. Mr. Widlar is interested in several accessory, lumber, real estate and steamship companies, and is president of the Champion company. Mr. Wildman, vice-president, is a financier of large interests, and Mr. Greif, secretary and treasurer, is heavily interested in a number of Cleveland manufacturing concerns. H. D. W. Mackaye is vice-president in charge of production and designer of the chassis. He has been employed by the Mora, Jenkins, Croxton-Keeton, Metzger, King and Keeton companies.

—

N. A. C. C.'s New Dealers' Arrangement for National Shows

NEW YORK, Nov. 27—The dealer arrangements for the national shows in New York and Chicago have been considerably simplified. Manufacturers will supply lists of dealers, and these lists will be checked and so blended that the name of a dealer cannot appear more than once. This means that if a dealer handles several lines of cars his name will appear but once instead of several times, as in the past. To each of these dealers will be sent three single admissions for his personal use. Dealers in important cities will receive three additional tickets, also intended for their personal use. In addition to these tickets, which will be sent direct to the dealers, each exhibiting member of the N. A. C. C. will receive a limited number of blank tickets to be distributed by the dealer to his representatives.

—

Three More Accessory Exhibitors

NEW YORK, Nov. 28—The Motor and Accessory Manufacturers have allotted space to three more accessory manufacturers for the New York and Chicago national automobile shows. This makes the total 343. They are: The Syracuse Malleable Iron Works, Syracuse, N. Y., maker of axles and castings; the Universal Motor Products Co., Indianapolis, winter tops for Fords, at both shows, and the Ericsson Mfg. Co., Buffalo, maker of the Berling magneto, at New York only.

—

New Era Buys Accelerator

DETROIT, Nov. 27—The New Era Spring & Specialty Co. has purchased the Ford foot accelerator formerly manufactured by H. E. Petrie of Battle Creek. About $8,000 was involved in the transaction.

—

Specialty Mfg. Co. Organized

DETROIT, Nov. 24—The Specialty Mfg. Co. has been organized at Minerva, Ohio, to make automobile accessories.

Drivers To Build Racing Cars

De Palma, Rickenbacher and Chevrolet Will Manufacture Machines in Detroit

DETROIT, Nov. 27—De Palma, Rickenbacher and Chevrolet are going to manufacture racing cars for their own use in the 1917 speedway campaign. Rickenbacher, who is entered in Los Angeles for the 150-mile Ascot race, will come to Detroit to build a team of racing cars to be owned by W. Weightman, III, of Kenova, W. Va. Chevrolet will work over the three Frontenac cars built jointly by himself and Joseph Boyer, Jr., this year. De Palma will devote himself to the De Palma Mfg. Co., which is to build special speedsters for those who want cars of that type.

—

Two Killed at Uniontown Speedway Practice

UNIONTOWN, PA., Nov. 27—C. M. Heist of Sharpsburg, Pa., and F. E. Bush of Pittsburgh, his mechanician, were killed to-day while traveling 60 m.p.h. on the local automobile speedway in preparation for qualification tests for the race on Thanksgiving Day. The front axle of the car broke.

—

Swiss Magneto Moves to Monroe

MONROE, MICH., Nov. 25—The Swiss Magneto Co., manufacturer of Swiss high-tension magnetos, has moved from Chicago to this city, having bought out the Elkhart Mfg. Co., and now occupies its factory. The new facilities will enable the production of Swiss magnetos to be considerably increased. No change in personnel will be made. The manufacture of Elkhart magnetos, which were the product of the Elkhart company, will be discontinued, it is understood.

—

Issue Gasoline Cards in France

PARIS, FRANCE, Nov. 23—Gasoline tickets and a ban on the use of private automobiles, it is stated, is part of a scheme in this country, for regulating the consumption of food and other supplies. If necessary, the government will forbid the running of any automobiles except public or semi-public machines.

—

104 Cars Burned in St. Louis

ST. LOUIS, Nov. 28—One hundred and four Overland cars were destroyed here yesterday in a fire in a wing of the warehouse of the Cedar Street Warehouse and Storage House. The machines were the property of the Willys-Overland Co. and were insured through the Toledo office. All were intended for Southwestern distribution. The local distributer says that the loss will not cause immediate inconvenience. Eight hundred additional cars of various makes in the main storage house were saved by closing of fire doors.

—

White Detroit Battery Sales Mgr.

DETROIT, Nov. 28—C. E. White has become sales manager of the Detroit Battery Co., this city. He was formerly connected with the General Electric Co.

—

King Trailer Co. Formed

ANN ARBOR, MICH., Nov. 28—The King Trailer Co., this city, has been organized to make trailers and has purchased outright the Ann Arbor Buggy Co. L. C. Long is vice-president and city sales manager of the Chicago branch of the Federal Motor Truck Co. He was formerly New England sales manager for this company.

—

Victor Motor in Jenkintown

WILMINGTON, DEL., Nov. 27—The Victor Motor Co., which recently purchased land at Claymont, Del., for a plant, has decided to locate at Jenkintown, Pa.

—

Manly Truck in New Plant

CHICAGO, Nov. 27—A new factory in Waukegan, Ill., a short distance north of here along the lake shore, has been secured by the Manly Motor Truck Co., which recently put the Manly truck on the market. Tht new plant will be occupied about Dec. 1.

—

Marvel Accessories Capital Increased

CLEVELAND, Nov. 27—The Marvel Accessories Mfg. Co. has increased its capitalization to $100,000, and a new factory building, which will greatly increase output, is now under construction. When completed more than 45,000 sq. ft. of floorspace will be available.

—

Logan Leaves Logan-Fischer Co.

CLEVELAND, Nov. 24—C. M. Logan, president of the Logan-Fischer Motor Co., Chalmers distributors, is severing his connection with that firm.

—

Hupmobile Tour Reaches Santa Fé

DETROIT, Nov. 27—The Hupmobile capital-to-capital party reached Santa Fé, the thirty-fourth capital in its journey, on Nov. 23. The car is now on its way to Phoenix, Ariz.

—

Stern-wear Tubes on Market Dec. 1

ST. LOUIS, Nov. 27—The Efficiency Oil Corp., of this city, announces that Stern-wear inner tubes, guaranteed to wear 20,000 miles, will be placed on the market from the new factory here Dec. 1.

Bed Rock

THE way in which automobile engineers this year have shown an inclination to get to the real bottom of subjects is very encouraging. There are many things in connection with automobile engineering that have been haphazard and rule of thumb, and they are mostly things that have been good enough in the past but are not good enough now, other parts of the chassis being improved so greatly. Such an example is the paper on retardation printed on another page, for it deals with primary forces and touches not at all on mechanical detail. Another constant subject of discussion during the year has been crankshaft balance, mainly a theoretical subject, the theory being forced upon us by the obvious imperfection of older designs.

There are many other things; lubrication is one, carburetion another and spring action a third, which may be mentioned as matters which require much more scientific treatment, and it would be easy to extend the list. The great thing, however, is not so much what has been done and is doing now, but the spirit of the thing. These discussions are lifting automobile engineering up to a higher plane; they mean that the automobile engineer of the future will need as good a scientific training as any other.

In its infancy the automobile industry was looked down upon by other branches of engineering because it had no theoretical basis; and in very truth it was once all a cut and try proposition. This is no longer so, and the cut and try methods of design and manufacture are dying, surely if not yet, very rapidly.

The automobile has really created a new section of engineering much broader than the road vehicle field. It has created the engineering of light structures, the engineering of weight saving. From the motor car chassis the aeroplane has grown, the high-speed boat has come into being and even railway engineering has felt the influence. This influence is but at its beginning. In the future we shall see much more machinery economical in use because light in weight, and all of it should go to the credit of automobile engineering. Let the good work go on.

Generator Reliability

THE only attention now needed by the electrical equipment of an automobile is the regular examination of the battery and occasional oiling of the generator and motor bearings. Adjustments of any kind are hardly ever provided by generator manufacturers, and they all state with emphasis that the less the owner knows of the existence of the commutator and brushes the better.

A generator and a starting motor should have an expert examination every 20,000 miles or so, or if they give trouble, but nearly every trouble that can occur happens outside the generator, which is about the most reliable part of the whole equipment.

Manufacturers list their troubles with generators as due to three things, over lubrication, under lubrication and "tinkering." Other troubles are all traceable to some accidental fault in manufacture and are correspondingly extremely rare. The reason for this is that the modern electric generator is extremely simple. It is far simpler than a magneto, for example. It did not take the public long to realize that any ignition trouble within a magneto was so rare that it need hardly be considered, and they would tackle spark plugs and wiring many times before commencing to investigate the internals of the magneto. Slowly, the same thing is becoming true of the electrical equipment; the generator is being suspected last of all.

Needs Little Attention

Like a magneto a generator is designed to run without attention, and there is no attention that can be given it which will help it to run properly beyond frequent, gentle lubrication. Its brushes require attention far less often than even the breaker points of a magneto, and when they do need touching it is usually a case of renewal rather than of adjustment. Never touch a generator until every detail of the battery and the wiring has been tested, not once, but several times, and thoroughly at that. This will be found the best policy at all times.

Commutator sanding and the fitting of new brushes are jobs that have to be done at rare intervals and they are not difficult, but they should never be attempted by anyone who has not been shown how by some man with experience in this work, otherwise the last state of the commutator may easily be much worse than the first.

Electric Systems Simpler

Better Manufacturing Feature of Starting and Lighting Equipment Progress in Year—Fewer Types Electrically and Mechanically — Two-Unit Gaining Steadily — More Generators with Ignition Combined—General Reduction in Weight

By A. Ludlow Clayden

THERE has been no really large change in the design of lighting, starting and ignition apparatus during the year of 1916. Every trend seen last year is seen again at present. The starting motor itself is almost eliminated from this discussion because it is so extremely simple that changes in its electrical makeup are unthinkable. The generator is becoming a better manufacturing proposition as the different big producers tool up for more and more each, of a decreasing number of models, for the innumerable patterns and designs each "special" in some way that the leaders of the industry were being forced to make two years ago, have been cut down and down again till unreasonable modifications are a minimum. The time is not far off when the generator business will be as standardized as carbureter manufacture. This is the case already in some plants, where the owners have had the courage to say to the automobile industry, "Gentlemen, here are our models of generator, we would like to have you choose one, but if none will suit you then please take your business to some other plant." Other plants not quite so courageous have gone a part of the way and persuaded some of their customers to give up needless petty individualities.

Concentration on Types

There is another thing, too, that has had an effect in improving the factory conditions, and this is that the electrical firms have been able to pick the types on which to concentrate. Some of the largest makers very wisely have been making machines of several different electrical systems. These they have sold in thousands and they have their records in service. In this way the most reliable out of two or three systems is quickly discovered, and a firm can concentrate on one system without any fear that they may not have made the best choice. The mere matter of size of generator had to be settled by time and experience, and we can see now that many machines being made two years ago were larger and heavier than they needed to have been. We have arrived at the light-weight generator by a series of successive easy stage reductions in dimensions. The substitution of press work and stamped parts for castings and forgings has enabled pounds of weight to be saved, but it has taken time to obtain and install the necessary presses, so here again a tendency observed last year is seen intensified at the present time.

Two-Unit Systems Almost Universal

It has become an accepted fact now that there are limits of rotative speed beyond which it is uneconomical to drive an armature, so this practically confines the single unit dynamotor with a constant gear connection with the crankshaft, to fairly slow speed engines. In cases where the engine runs upward of 2000 r.p.m. it is rare to find anything except two unit systems, excepting those few single units which have one connection to the crankshaft while being driven and another of lower ratio when they are operating as the starting motor.

For starting motor drives the Bendix pinion is still the almost universal equipment and it is unlikely that this eminently efficient and simple device will be displaced for a long time to come. Magnetic shifts are used on a few cars and mechanical shifts have not disappeared altogether, but there are very few of these remaining.

A matter which is still very much in the air is that of the attachment of the generator and the starting motor to the crankcase. At first almost all generators were designed to fit on a platform after the fashion of the magneto. Next, came round body generators which were clipped in cradles cast on the side of the crankcase and, finally, we now have the flange type of generator or motor, which has a large flange with three or four bolt holes on one end of the frame, attaching to a machined surface on the back of the crankcase front end, in the case of the generator, and to a facing on the crankcase rear arm in the case of the motor.

This flange mounting is every bit as secure as the platform or cradle mountings, especially with the present-day low weight of electrical units, and it is cheaper for the automobile manufacturer, because on a crankcase there are already several surfaces which have to be machined into planes at right angles to the axis of the crankshaft and it is little trouble to machine the necessary extra two faces for the generator and motor. The armatures of these two machines must be parallel to the crankshaft, and with a platform mounting some precautions in fitting have to be taken to insure the parallelism, thereby making the crankcase machining a little more expensive.

Flange Mounting Not Always Possible

A trouble, which is retarding the adoption of flange mountings more generally, is that it is not always possible to adapt this style to existing engines without alterations in the design of the crankcase. A committee of the Society of Automobile Engineers is investigating the situation, and has been doing so far nearly a year, and it has discovered a strong tendency amongst engine builders to make their new models suitable for flange mountings. This being so the S. A. E. expects that it will be able to standardize three flanges of different sizes, and that these standard ends for generators and motors will come steadily into use; though it may take some years for this to happen in cases where engine design has first to be changed.

One big advantage of the flange mounting is that it permits adjustment of the centers in the front end. If the flange has one round hole and two slotted holes it can be swung a little on one of the bolts, so allowing adjustment of the degree of mesh of the front end gears, or even effecting adjustment of the chain where a chain drive is employed for the generator. The starting motor does not need this adjustment, and may therefore have a standard flange somewhat different from that for the generator. The trend toward the use of the flange has begun and one of the largest suppliers is putting on all possible pressure to have it adopted by every one of its customers, but it will need another year yet before the work now being done by the electrical firms will show its effect to the full as they are pushing for flange mountings on the 1918 cars rather than for 1917 business, which is practically all closed.

Unit Ignition Increasing

The trend toward unit assemblies of generators with ignition distributers is very marked this year. Not only does this eliminate one of the drives from the engine, but with a normal sort of generator location it usually brings the distributer into a position somewhere nearly midway of the cylinders, so that the high-tension leads to the spark plugs can be short and direct. There is another small advantage, in that the timing can usually be made very exact, because the pitch of the fine teeth of the bevel or spiral gear drive for the vertical shaft will differ from that of the front end gear, thus offering a chance for a sort of differential setting.

The manufacturers of generators do not appear to have any preference with respect to the location of the ignition distributer. The demand for combining it with the generator appears to have come from the automobile manufacturer and it depends upon him whether this will be the most common type in the future. One tendency with respect to ignition units is worth noting. Two years ago a number of generators were being put out with the ignition breaker and distributer mounted on the end and appearing from the outside almost exactly the same as a magneto distributer. These types are still being made, but they are not being used to anything like the same extent as are the generators combined with a cylindrical distributer on a vertical shaft.

There are two reasons which may explain this situation. The first is that the provision of a vertical shaft on the end of a generator will allow a number of different kinds of distributers to be fitted, so a manufacturer need not purchase the generator and the ignition device from the same firm, even if he uses them in unit combination. The other is that the cylindrical distributer on the vertical shaft is usually less liable to be rendered inaccessible by manifolds or other parts on an engine.

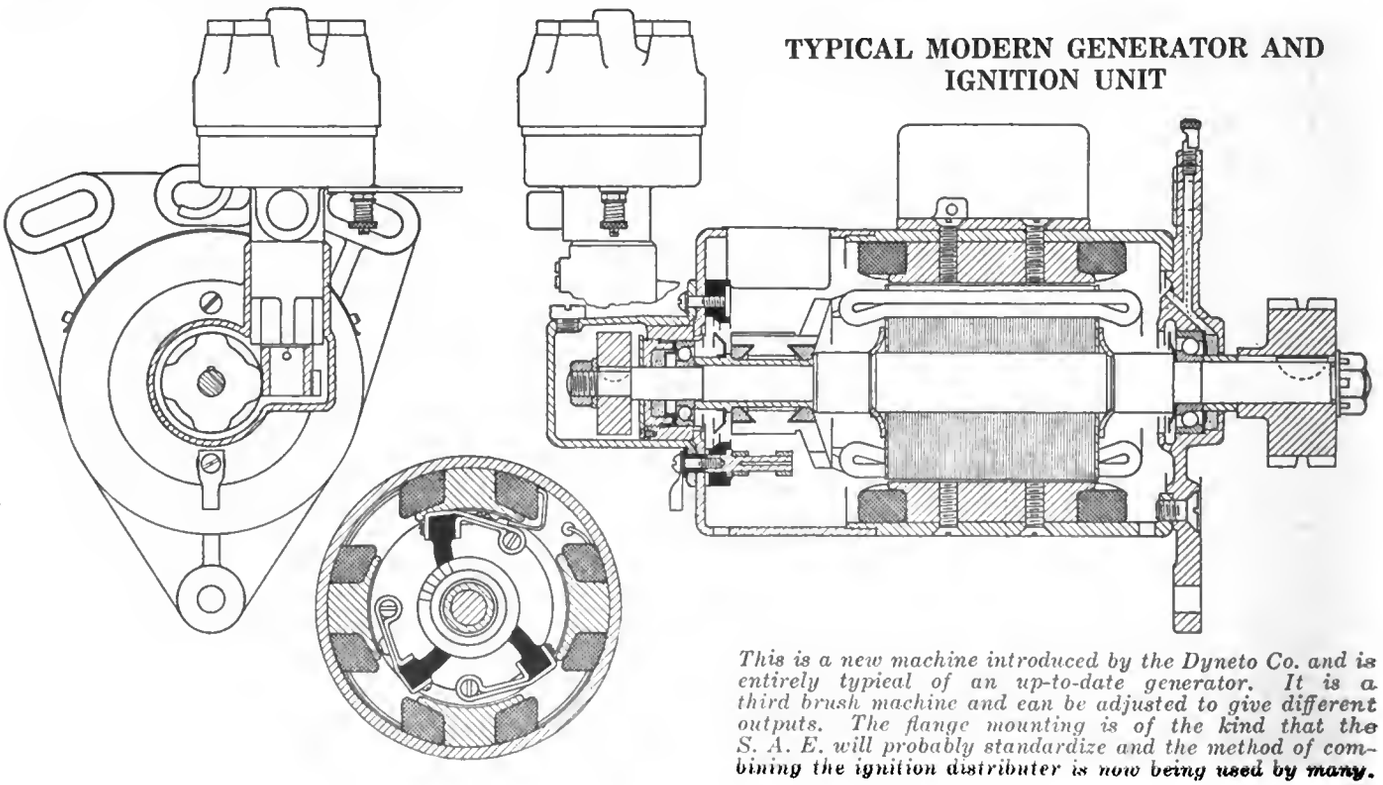
There is another point which is sometimes of importance in determining the choice of a unit generator and igniter. With the magneto type of distributer and contact breaker it is not usually so easy to carry the armature shaft out at both ends of the generator. When the vertical distributer is used it is quite easy to extend the armature shaft so that a water pump or some other accessory can be driven tandem with the generator. With a flange mounting for the generator and an armature shaft carried right through, a drive for a tire pump can be arranged very conveniently and the pump will not interfere with the accessibility of the distributer.

Fewer Regulating Systems

For holding the voltage steady throughout a very wide range of armature speed a large number of different schemes have been tried. Three years ago there was very little indication as to what would be the ultimate choice of manufacturers. Even a year ago it would have been hard to forecast the situation to-day, but it is now possible to state quite definitely that the third brush system of regulation is far the most popular and that the vibrator controller for either voltage direct or for current is second favorite.

It also appears now that we shall almost certainly see several systems of regulation continuing in use for many years. For very many purposes it is hardly possible to improve upon the third brush system. For cars having a big lamp load, a rather lighter machine can be built with a vibrator control, while the bucking coil and some other system of control are often preferred in special cases.

The action of the different controlling systems has been explained several times in THE AUTOMOBILE, but the two



TYPICAL MODERN GENERATOR AND IGNITION UNIT

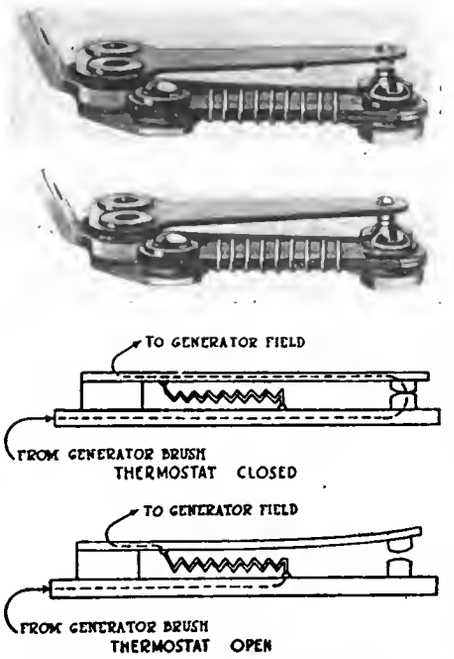
This is a new machine introduced by the Dyneto Co. and is entirely typical of an up-to-date generator. It is a third brush machine and can be adjusted to give different outputs. The flange mounting is of the kind that the S. A. E. will probably standardize and the method of combining the ignition distributer is now being used by many.

principal controls may be outlined briefly once again. There are two main brushes on the generator from which the current is taken and this current has two paths. One is the outside path to the battery, etc., the other is the internal path round the field magnets. Now, if we assume that there is 6 volts difference of potential between the main brushes we could regard one brush as being plus three and the other brush as minus three. If we apply a third brush midway between these two its potential would be zero. If, therefore, we take a wire from the third brush, wrap it around the poles of the field magnet and take it back to either of the two main brushes there will be a difference of 3 volts between the two ends of this secondary field magnet winding. This means that a current will flow through this second winding as well as through the main winding.

As the speed of the armature varies the magnetic lines of force are distorted. At very low speed they go straight from pole to pole and as the speed rises they are dragged around by the armature so that they take up an angular position. The effect of this is to vary the potential at the point on the commutator where the third brush makes contact, so that the current flowing from the third brush to whichever of the main brushes it may be connected varies with the speed of the machine. It is possible so to place the third brush that the current from it will assist the excitation of the field magnets at low speeds and oppose it at high speeds.

The action may be compared to that of a fan placed in a flue from a stove. When the stove is burning freely we can set a fan to blow up the flue, thereby increasing the draft and encouraging the fire. When the fire is burning freely so that the natural draft up the flue is very strong, we could decrease the rapidity of the draft by reversing the direction of the fan and blowing *down* the flue instead of *up* it.

It is obvious that, with this third brush system, the exact nature of the current produced from any one machine will depend upon the position of the third brush relative to the other two. If we want the generator to start charging at a very low speed we can set the third brush so that the current from it will assist the magnetization of the fields very strongly. If we want to reach the peak of the output of the generator at a higher speed we can move the brush so as to reduce or even entirely remove the assisting feature, letting it act only in opposition at high speeds. Thus the third brush machine has a possibility for adjustment. Nearly all third brush machines are so made that the manufacturer can adjust it, but very few indeed have an adjustment which is intended to be touched outside the factory. The reason for this is that the adjustment must be operated intelligently. It is a useless thing to anyone who does not understand its function. It used to be thought that the difference in the average lamp load between summer and winter would make an adjustment imperative, but this idea has lost ground steadily and has few supporters to-day. The reason is two-fold; first, batteries will withstand a greater degree of overcharging than they used to do, and secondly, generators are commonly so constructed that they produce the maximum charging current at fairly low speed and considerably less current at high speed. This means that the reduction in speed which accompanies night driving actually increases current output. Furthermore, with some of the vibrator controls, the output of the generator depends only upon the condition of the battery and, if the battery is full, the generator will deliver very little current, scarcely more than enough just to keep the battery in proper condition.

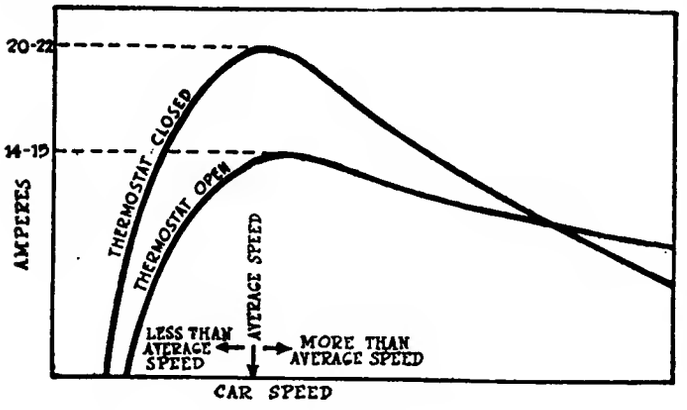


Photograph and diagram of connections for Remy automatic output regulating thermostat

The Remy company, however, considers that some sort of differentiation is required for the sake of the battery, and it has recently developed a very interesting device for varying the charging rate between summer and winter. If the generator is made so that it will carry the winter lamp load it is bound to do a certain amount of battery overcharging in the summer and, although this may not do the battery any real injury it is bound to evaporate the electrolyte a little quicker than it would otherwise do.

The Remy idea is very simple and it consists of an automatic device controlled by temperature which switches a resistance into the field windings as soon as the temperature of the generator rises above a predetermined point, usually about 150 deg. The device consists of a pair of contacts normally kept together, one of them being mounted on a compound strip of two dissimilar metals. When temperature increases above 150 deg. this strip bends, so breaking the contacts and thereby throwing in the additional resistance coil.

The thermostat is mounted inside the generator, where it will normally be at about the same temperature as that prevailing throughout the coils and body of the generator. It is proposed by the Remy company to proportion the additional resistance so that the effect of throwing it in is to reduce the current about 30 per cent. An automatic device



Effect of Remy thermostatic output control

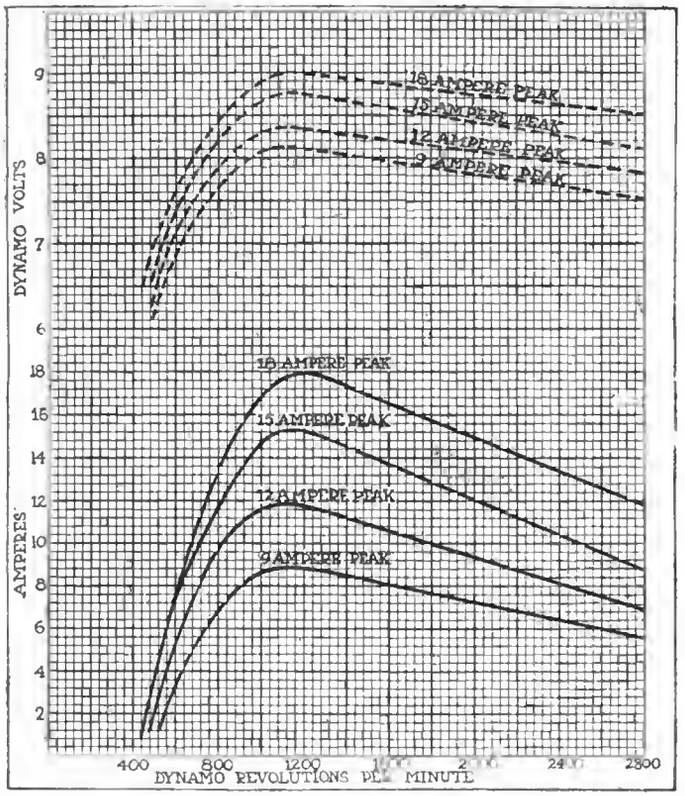
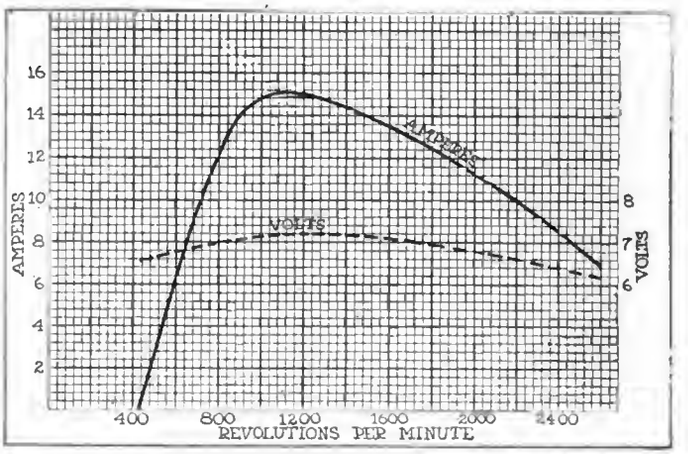
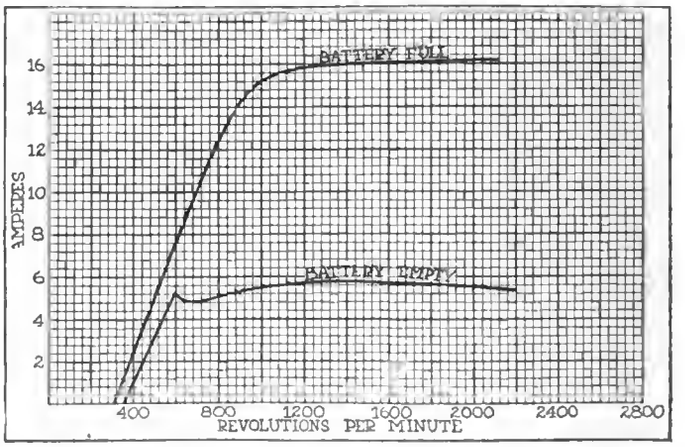
Characteristic Curves From Different Controls On Various Generators



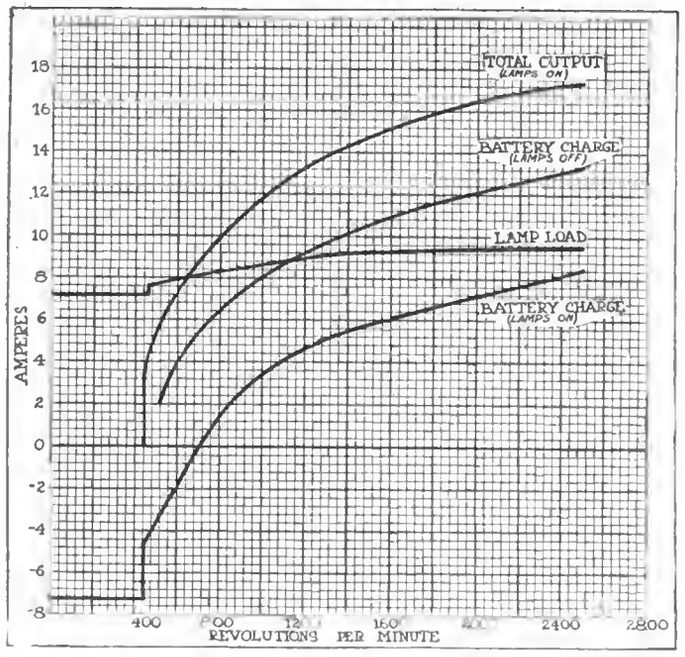
Voltage and ampere curves obtained from the same generator with third brush regulation obtained by altering the adjustment of the third brush. These give an excellent idea of the adaptability of this kind of regulation to various conditions, a very desirable feature



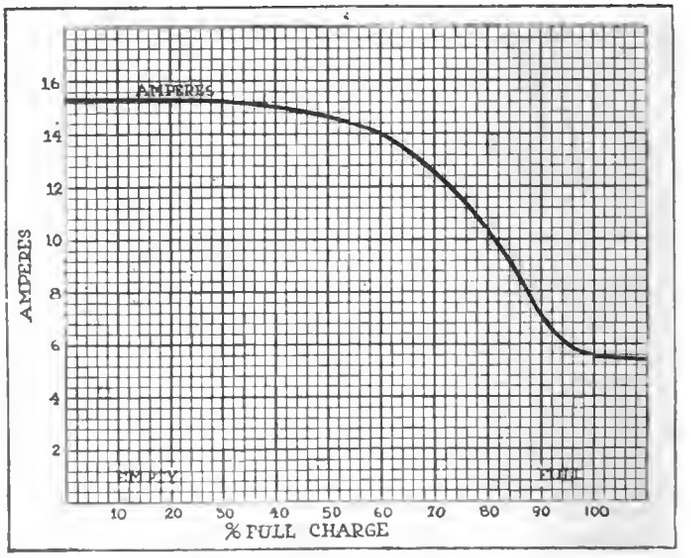
Characteristic curves from third brush generator plotted to a different scale



Shows how the state of charge of the battery affects the output from a generator with voltage regulation by vibrator



Bucking coil regulation curves showing characteristics, which, as may easily be seen by comparing them with the curves in the cuts appearing above, differ greatly from those of the third brush machine



Another way of showing the effect of the state of the battery on a voltage regulated generator. The curve is the output measured at successive intervals of time as the generator brings the battery from full discharge to full charge

of this nature should have the advantage over anything requiring manual operation.

Several generator makers give directions in their instruction books for hand adjustment of the third brush and recommend its use, so it is quite probable that automatic or hand settings will return to favor in course of time.

Vibrator Like a Throttle

Vibrator control operates quite differently from the third brush system. In its simplest form there is an ordinary shunt coil passing from one main brush to the other and no subsidiary winding on the pole pieces. The shunt winding is connected permanently to one brush and its connection to the second brush is controlled by the vibrator. This vibrator is a spring reed furnished with contacts and with a small electro-magnet. The coil of this magnet is placed somewhere in the circuit so that if the current in it increases above a certain point the reed is attracted and the contacts either made or broken. With the reed in one position there is direct connection of the second brush to the end of the shunt winding, which means that as much current as possible will be flowing around the magnet poles. If this current becomes too strong, the reed of the vibrator moves and the change in the contacts thus caused switches a resistance coil into the shunt circuit. The effect of this is instantly to reduce the amount of magnetization, which in turn reduces the current. As soon as the current drops the reed of the vibrator is released and flies up, thus cutting out the resistance and returning the state of affairs to what they were immediately beforehand. This action is performed with great rapidity and, returning to our stove analogy, it is as though there was a valve in the flue which automatically closed as soon as the draft passed a certain degree of vigor. The instant it shuts the draft ceases and the valve automatically reopens only to shut again as the draft increases once more.

The vibrator control was developed previous to the days of the automobile, being used for other electrical work, and it was its great reliability in this service which suggested the idea that it would be satisfactory for automobiles. It has proved wonderfully reliable and has the advantage that it can be assembled as a unit separate from the generator itself. The vibrating reed, the resistance coil and the little electro-magnet are commonly all mounted in a sealed case which is attached either to the body of the generator or to some other convenient point on the car, although mounting on the generator is the most usual method. In the rare event of anything going wrong, the whole control unit can be replaced as easily as changing a spark plug. Comparing the two systems, the third brush is the simpler and the cheaper to make. It has no parts which can possibly fail or give trouble excepting the brush itself. The two drawbacks are that the characteristic output curve is not quite so close to the ideal as can be obtained with vibrator regulation, and the fact that there are three brushes instead of two is bound to make a slight difference in the rapidity of commutator wear. These two drawbacks, however, are extremely small and can be largely offset by a slight increase in size.

Little to Choose Between Systems

The vibrator controls enable the generator to be somewhat smaller and lighter and usually they will bring a discharged battery back to the fully charged state most rapidly. The drawback, if indeed it can be called one, is the presence of a moving part and contacts which are made and broken constantly, but since the life of the vibrator is apparently very much greater than that of the brushes and other parts of the generator this is a very small point. Thus, in weighing up between the two systems, when you consider the type of output curve and the weight and the cost it will often be found that there is very little to choose.

A point which has been very much discussed is the car speed at which the generator should commence to charge. This, however, is of small importance by itself. It cannot be considered alone any more than we can consider the diameter of a valve without any knowledge as to its lift and timing. The essential thing is to have such a generator and to drive it at such a speed that we can be sure of an output equivalent to the full lamp and ignition load at an average night-driving road speed. The practice of various manufacturers differs a good deal, but almost all of them find it necessary to provide this amount of current at a speed of 15 m.p.h. Some of them consider 12 m.p.h. is better. In any case it is between 12 and 15 m.p.h. that something approaching the full output of the generator should be reached. How much below 12 m.p.h. the cut-in should take place depends upon the characteristics of the generator. That is to say, it depends upon how rapidly it comes up to full output.

May Raise Generator Speed

The great majority of generators are now geared to run one and one-half times crankshaft speed. Whether this is going to be conventional practice for many years is debatable. More than one manufacturer of electrical apparatus considers that an increase in armature speed would be desirable because it would permit the generator to be smaller and lighter. The limitations of speed are almost entirely mechanical. With an engine capable of revolving 3000 r.p.m. we must be certain that the armature commutator, etc., will withstand prolonged running at 4500 r.p.m. if we are going to us a 1½ to 1 ratio. Using a 2 to 1 ratio would mean that the armature would need to be safe at 6000 r.p.m. Manufacturers have had to discover methods of construction which enabled the armature to be manufactured conveniently and which also provided strength to resist the considerable centrifugal forces at these very high speeds. When the construction of an armature, consisting of bundles of wires wound round a peculiarly shaped piece of iron, is considered, the difficulty of resisting the disintegrating forces becomes apparent.

Self-Lubricating Bearing Popular

There is very little trouble with bearings, the loads are so light that these seem to be able to stand any number of revolutions. Ball bearings are used very extensively in mounting armatures, but there is a noticeable tendency towards the use of plain bearings and a most successful type has been a compound metal and graphite bushing. It is necessary with plain bearings to be sure of an adequate supply of oil, and this is usually arranged for by a form of lubricator in which sufficient oil for a month or two of running is carried in a little cup or reservoir and transferred to the bearing itself by a wick. The wick will always supply the same amount of oil per revolution, thus insuring an adequate supply and preventing an over supply. The electric manufacturers' service stations report that two of the commonest troubles are bearing trouble, caused by absence of oil, and commutator trouble, caused by too much oil. The average owner of an automobile either over-oils or under-oils it. Hence generator makers are trying, with good success, to devise forms of lubricators, like the wick lubricators, which make over-oiling impossible and carry so much oil that an adequate supply is guaranteed even if fresh oil is added only very occasionally. Several manufacturers have continued to use ball bearings because of their ability to run when quite dry, but the compound bushing containing a little graphite can also be run dry for a reasonable time without much damage resulting so that the present tendency is certainly toward plain bearings. This seems rather curious in these days when ball and roller bearings are being used more and more extensively, but there are two reasons which make the plain bearings preferable. One is that it is incapable of making any sound, and the other is that the clear-

ance between the armature and the pole pieces can be made rather smaller with plain bearings, which increases the electrical efficiency of the generator. However, we are getting small bearings of a greater and greater accuracy every year, so it will be very difficult to forecast what may be the eventual outcome.

Single Unit's Limited Field

The situation with respect to single-unit and two-unit systems is much the same as it was last year. That is to say, the trend toward the two-unit system is continued. The single unit which has but one driving connection to the crankshaft is giving excellent service and is still being used extensively on cars where the maximum of engine speed is not very great and where the cranking torque required is comparatively low. To give enough cranking torque a single unit in permanent connection with the crankshaft through a chain or gear has to be made larger than it would need to be did it operate as a generator only. It also has to run at a higher speed than would be the case were it only a generator. This is because the size and speed determine the cranking torque which the instrument can exert on the crankshaft.

Obviously, if we have a 3 to 1 gear ratio between the armature and the crankshaft we must have a much larger electrical machine than if we have a 20 to 1 ratio which is easily obtainable through the flywheel engagement.

This difficulty has been overcome in one or two cases by arranging a special form of drive so that the armature is driven at one speed when the machine is operating as a generator and at a much higher speed when acting as a motor. The best known example of this is, of course, the Delco system in which the armature is driven by the crankshaft from one end through an overrunning clutch and can be made to drive the flywheel from the other end, during which cranking period the clutch is in operation and the main drive is doing nothing, but electrically, this is practically the same thing as a two-unit system with the two units combined in one external casing. Possibly it is the great opportunities offered for patenting single-unit machines of this type and the impossibility of patenting two-unit outfits as such, which has encouraged the development of the two-unit system rather than of the "two speed" single unit. Undoubtedly, also, the two-unit system has been favored by automobile engineers because the generator is small and the motor so very small that it can be packed away in very little space.

As with almost every other new part of an automobile the design of the electrical equipment a few years ago was influenced largely by the demand for outfits which could be attached to engines originally designed to receive them. While this did not affect the electrical part very much, it did affect the mechanical detail profoundly, and it is really only now, at the commencement of the 1917 season, that it is possible to say the effects of this original influence have altogether vanished. Even now, however, very many generators and motors are being made to special designs because of the limitations imposed by the producers of old crankcase patterns. For instance, the inboard type of starting motor in which the Bendix pinion moves forward to engage the flywheel is simpler than the outboard pattern in which the pinion moves in the reverse direction, because in the former case it is only necessary to have the two bearings in the motor frame, whereas in the outboard type an additional casting with a third bearing the far side of the pinion is essential. It so happens, however, that the inboard type is difficult to apply to a good many stock engines with bell housing to the flywheel. Similarly with regard to the mounting of the generator, the geared centers in the front end fall very differently in different engines and this makes it hard to avoid the occasional use of special generator frames.

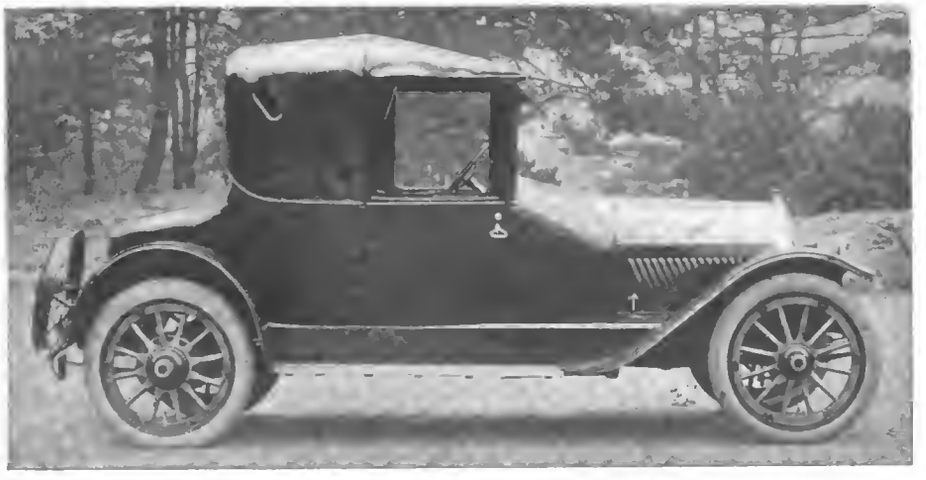
Time, however, will take care of things like this and we are within sight of the day when almost any stock electric generator and motor will fit almost any stock engine, a condition which is eminently desirable.

The application of either generator or motor to the side of the transmission case at one time appeared promising, as it frees the engine of a bulky part, but there is no indication whatever that this idea is likely to be considered except in a very few isolated cases. Probably on the engine is the best place for the generator, as it is most accessible there and well protected.

Steady, Sane Progress

Summing up, therefore, it appears that the electrical equipment record for 1916 is one of sane, steady progress without any prominent high spots. Changes have been mainly of the "settling down" kind; the elimination of peculiar or odd designs and a general bettering of manufacture. More real development work has been done with battery ignition where there have been a good many changes and a good many new things, and these will be dealt with in the next issue of THE AUTOMOBILE.

New Cabriolet on Oldsmobile Eight Chassis



New Oldsmobile four-passenger cabriolet mounted on the eight-cylinder chassis. It sells for $1,775

LONG low lines, flowing curves and German silver radiator with silver finish on lamps, hub caps and door handles are individual touches of the new cabriolet body mounted on the Oldsmobile eight chassis built by the Olds Motor Works, Lansing, Mich. The collapsible top has no exterior braces and can be handled from the inside by one man. Doors are substantial with large rattle-proof adjustable windows. The driver's seat is 15 in. in advance of the main seat which accommodates two passengers. A folding seat pivots under the cowl. The car sells for $1,775 f.o.b. Lansing. The compartment behind the driver's seat is of ample dimensions and can be used for parcels, gloves and other things of that sort.

Denmark — A Good Car Market

American Cars Are Rapidly Establishing Excellent Reputations for Economy and Durability—Field Should Be Further Developed —Industrial Conditions Similar to Those in the United States

DENMARK to-day presents one of the most rapidly growing markets for American-built automobiles and motor trucks, according to Knud A. Mammen, New York manager of Mammen & Drescher, dealers in American cars in Copenhagen. Mr. Mammen states that there are over 30,000 cars in use in Denmark at the present time, as compared with less than 2000 in 1912. The great bulk of these are passenger cars, there being comparatively few commercial vehicles, although there are some 200 taxicabs, which are not fitted with rubber tires, due to the high prices now prevailing for these in the Scandinavian countries.

Industrial conditions in Denmark at the present time are very similar to those in the United States, certain commodities having risen rapidly in price in consequence of the demands of the warring countries. Naturally a large number of people have profited by these developments, with the result that a new wealthy class has been created, the members of which have been dubbed by the general public "goulash barons." These people have been and still are large buyers of automobiles. In addition, farmers have profited by the high prices now paid for their products to such an extent that the majority of them have bought cars. Moreover, the Danish people have only recently awakened to the possibilities of the American car, and the normal demand has been growing at a rapid rate. An example of the interest displayed by the people of Copenhagen in United States of America cars was mentioned by Mr. Mammen, who said that two months ago he drove a new four-passenger American-built machine through the streets of the city one morning and that afternoon over twenty prospective car buyers came into the company's salesrooms with the cash in their pockets to pay for a machine on immediate delivery, but, of course, it was impossible to furnish what they wished at that time. Most of these people subsequently became owners of cars of that make in either the model they had admired or in some other style which appealed to them on making a further investigation. About three months ago similar conditions prevailed, every automobile dealer in Copenhagen having sold out his entire stock, and people were coming into the salesrooms every day with rolls of money to pay for cars which were not available on any terms.

Difficulty of securing shipping accommodations due to war conditions has been one of the greatest handicaps with which the exporters of American automobiles have had to contend. Mammen & Drescher, who handle Chandler, Pathfinder, Haynes, Elcar, and Singer cars, Chase and Duplex trucks, and Knox tractors, in addition to Fisk and other American tires, found that it cost them between $500 and $600 each for the larger cars when these were shipped crated, not including crating and carting and freight from the factory. By arranging with the factory to ship them the chassis knocked down and without bodies the firm effected a saving of 80 per cent. on the freight of each car. Upon the arrival of the chassis in Copenhagen they are taken to the company's shops and fitted with bodies of the European type and more in keeping with the desires of many of the purchasers than the standard American-built bodies appear to be. An interesting development of the present era of nouveux riches in that country is that the so-called "goulash barons" desire the bodies of their cars to be something out of the ordinary, and, as their tastes have not been very highly developed in this regard, the results are frequently grotesque. Sometimes they content themselves with a few flourishes of external ornamentation and perhaps a strikingly vivid coloring, and in other cases they order unusual and impractical body shapes. In the matter of interior arrangement of seats, color, and type of curtains, window operation, etc., they often demand the impossible, but are finally content to accept some approximation of their ideal, if the body builders cannot persuade them to accept a more

KNUD A. MAMMEN

EDITOR'S NOTE:—Our manufacturers of cars, trucks and accessories have frequently been informed that now is the time to develop and establish a world market for their products which will endure after the close of hostilities in Europe and many of them have taken advantage of the opportunities now offered for export trade. This article, based on data furnished by Knud A. Mammen, New York manager of the Copenhagen firm of Mammen & Drescher, and A. H. Anderson, chief engineer of the same concern, gives an inkling of the propitious conditions to be found in Denmark.

A. H. ANDERSON

MAP OF DENMARK, SHOWING SOME OF THE MAIN AUTOMOBILE ROADS

Touring is very good in Denmark, although the distances are of course small as compared with those in the United States. Roads are excellent, macadam and bituminous-surfaced highways preponderating. Those indicated by the black lines on the map are only a few of the more important thoroughfares connecting some of the leading cities of the country, but there are a great many more roads which have all the advantages offered by these and at the same time possess even greater scenic attractions. This is especially the case in the northern part of Jutland where some of the finest touring imaginable is to be found. Connections between the various islands of Denmark and also with the peninsula of Jutland are by ferries and the water trips lend a great deal of variety as well as giving some glimpses of very fine coast scenery. These conditions, coupled with the increasing prosperity of the country and the leaning evinced by the people of Denmark toward American cars, make that country a rich field for the American manufacturer

conventional but less conspicuous design for their machines.

An idea of the difficulties to be overcome in shipping cars from the United States to Denmark under present conditions may be gained by reviewing the necessary routine and red tape through which exporters are obliged to go before the cars are allowed to leave New York harbor. The Merchants' Guild in Copenhagen gives a declaration for orders which have to be viséed by the British Consul and by the Automobile and Cycle Merchants' Association, which is somewhat similar to the National Automobile Chamber of Commerce in this country. The matter then goes to the Scandinavian-American steamship line, which is the only one carrying American automobiles direct to Denmark. The steamship company cables to the agents in New York who handle its shipping from this country. These agents then notify the exporter what accommodations can be obtained for shipping the cars, giving ship, date, etc. It is then necessary for the exporter to write to the British Embassy at Washington, giving complete details of the order and describing all matter to be shipped thereunder, and also giving the names and addresses of consigner, consignee, etc. Upon receipt of an assurance for the goods and a permit from the British Embassy the cars can then be placed on the dock, after which shipment is a mere matter of routine with the steamship company.

Shipping Improved

For about two years after the beginning of the European war automobiles could be shipped to Denmark only on freight boats, and frequently it was impossible to secure space on any of these for long periods at a time, due to the enormous quantities of war munitions which were being sent abroad for the use of the belligerent nations. Now the situation is greatly improved, not only because the exports of munitions have greatly decreased in volume, but also because passenger boats are now available as carriers of automobiles and motor trucks.

Tires Hard to Get

The restrictions enforced by Great Britain upon the shipment of rubber, including tires, to European countries naturally constitute another handicap on the exporter of cars from the United States to Denmark, because it is not only impossible to ship machines fitted with tires, but it is also exceedingly difficult to secure tires with which to equip them when they have arrived in Denmark. All tires must pass through London, and the strictest sort of supervision is exercised in England and also in Denmark to prevent the tires, or, in fact, rubber, in any form, from reaching Germany. For some time after the outbreak of hostilities unscrupulous persons took any means of securing tires, which they could sell in Germany at very high prices. When they were unable to obtain a sufficient quantity by buying in the open market or through private channels they stole them from cars and shipped them to Germany. To check these practices a system was developed by which no one could buy a new tire without

turning in the old one on the deal.

The importance of the first impression made by an American-built car on the market in Denmark is evident from the experience of Mammen & Drescher, as cited by Mr. Mammen, with the first machine the firm imported from this country. This car, a Chandler six, took part in a big reliability run held soon after its arrival in 1914, and made an enviable showing under particularly adverse conditions of weather, road, etc. As a result a demand immediately sprang up for these cars, and that particular machine has been sold three times, the owner each time turning it in for a new car. Similar experiences with the other American cars the company handles have confirmed them in their belief that it pays to demonstrate the good qualities of the machine for the benefit of the Danish public, which has never had very much experience with American automobiles until the last two or three years.

Showrooms of Mammen & Drescher in Copenhagen, Denmark. These are situated in the business district near the station through which the prosperous citizens make their daily trips between home and office. Note the American-built cars at the curb ready to give demonstrations, for which they are usually in great demand

There are too many automobile dealers in Copenhagen, Mr. Mammen says, who know practically nothing about the cars they sell. These dealers cannot give satisfactory service to the people who purchase their cars, and the natural result is that the machines they represent acquire a reputation as unsatisfactory in various ways. The same situation does not exist with regard to tires and accessories, as the dealers are more familiar with these and seem to handle the service matters in regard to them more satisfactorily than for the cars.

No Automobile Row

There is no automobile row in Copenhagen, which is the largest city, the capital, and the most extensive automobile market of any part of Denmark. The various salesrooms, garages, service stations, shops, etc., of the dealers in automobiles and accessories are spread over the business, and part of the residential, section of the city, and apparently only a few dealers have been thoughtful enough to secure locations advantageous from the viewpoint of passing traffic, etc. The salesroom of Mammen & Drescher, which is illustrated on this page, is fortunately situated, Mr. Mammen points out, being so placed in the business section of the city that practically all the prosperous citizens who are legitimate prospects as car buyers must pass it on their way to and from the station on their daily journeys between their offices and their homes in the suburbs or outlying residential districts.

American cars are now most popular of all in Denmark and bid fair to continue so after the close of the war, owing to their low price, durability, simplicity, and ease of upkeep. The possibilities of this country as a field for the United States of America car manufacturer are very great at the present time, and, if properly developed, the trade of our automobile industry with Denmark should grow to very large proportions in the future. When it is realized that the twenty islands and the peninsula of Jutland, which constitute Denmark proper, have a population of approximately 3,000,000, that the city of Copenhagen alone has over half a million people, and that there are about a dozen other cities with populations ranging from 10,000 to 70,000, it is readily seen that here is a field which our makers should not neglect. Then, too, the influence of good reputations established by American-built cars, trucks, and accessories in Denmark will have a very considerable effect in facilitating the development of our business relations with the insular possessions of that country.

American cars have had little competition to meet in Denmark during the last two or three years. Shortly after the outbreak of the war a number of persons, perceiving the increased demand for automobiles in the country, went to Germany and bought up all the French, English, Italian, and other cars they could secure and sold them at a big profit in Denmark. There is a car called the Scania-Vabis which has been sold in large numbers in Copenhagen and other Danish cities since the outbreak of the war. This car is made in Denmark from parts imported from Sweden. It is a rather heavy car and the output is necessarily small, so it does not offer very serious competition to dealers in American cars.

Money Easy to Get

Industrial conditions in Denmark at present are very similar to those in this country. The banks are in excellent condition and money is easy to get, so that dealers have no difficulty in securing financial backing. Thus cars can be sold on the time-payment plan if desired, though there is at present very little call for this arrangement in that country. As Denmark is primarily an agricultural center, the high prices for farm products which the war has caused are responsible for the widespread prosperity to be found among the Danish farmers, who, Mr. Mammen says, are buying cars fast, Fords predominating. No fat or butter is allowed to go out of the country except to England but the large fishing industry of Denmark has profited enormously from the war as it furnishes fish not only to England, but also to France and Germany. There are practically no cattle to be seen browsing in the fields, as an enormous number have been killed and the meat sent to Germany and those remaining are carefully guarded as beef sells for about $1 per pound. Other farm products have increased in price to a marked degree during the past 2 years; milk is 4 per cent higher than at the outbreak of the war and wool 100 per cent higher; butter costs 60 cents per pound, and all meats are far more expensive. Naturally the high price of wool and other cloth-making materials has had a great effect on the price of clothes, which are considerably more costly in every par-

ticular than was the case in that country 2 years ago.

One phase of the situation which must not be overlooked by the American manufacturer is that the farmers, attracted by the high prices paid, have sold practically all their horses for war purposes and these men are almost all logical prospects for the sale of American-built farm tractors and motor trucks.

All Plants Rushed

In the manufacturing field all the aeroplane, war munitions, and textile factories in Denmark are doing an enormous business and the stocks of these companies have soared to remarkable heights. Ammunition supplies and machine tools for factory equipment are produced for Russia in tremendous quantities besides a large output to other countries. The stock of one concern manufacturing these goods sold at $45 a share in 1914 and it is now quoted at over $530. The securities of shipping concerns have also had a rapid rise, the $100 par stock of one company being quoted at over $1,700.

Business morals have declined in Denmark in company with those in other European countries not involved in the great war. People realize that existing conditions are only temporary and many of them have made up their minds to make their fortunes quickly and without particular regard as to the means employed.

A Fine Touring Field

Denmark presents an unusually attractive field for touring and the roads are very smooth and well kept, being largely of macadam or bituminous surface. There is at present a law in effect which prohibits the use of all side roads by cars of over 2000 lb. This has no effect on the smaller cars and only restricts the larger ones to the main highways, which is a hardship only in so far as missing delectable bits of scenery in out-of-the-way places are concerned. It is very probable that this law will be repealed before long.

Roads Are Excellent

Of course all the islands as well as Jutland are covered with a network of good roads but some of the more important ones are indicated in the map on page 926. The country inland is rather flat but along the coasts there are magnificent stretches of rocks and cliffs, the latter being of white chalk in some instances as at Klint in the island of Möen. There are numerous beautiful boat trips between the islands, and in passing through the inland sections of beech woodlands and little lakes overhung by trees present a continuous variety to the neatly fenced fields and cozy cottages. In Northern Jutland there are some particularly lovely bits of scenery in the neighborhood of the chain of lakes running from Aalborg, a city of some 40,000 inhabitants, to the western coast.

Prospects in the Cities

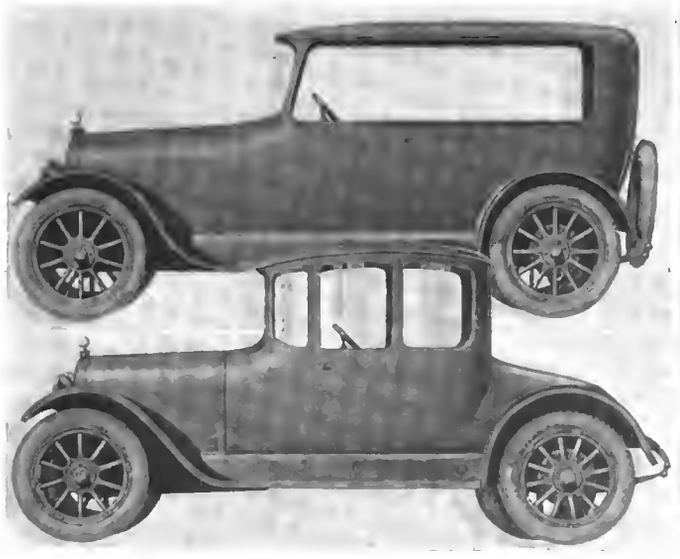
Some of the leading cities of Denmark which offer possibilities to the American car manufacturer are the following, as indicated by their approximate population:

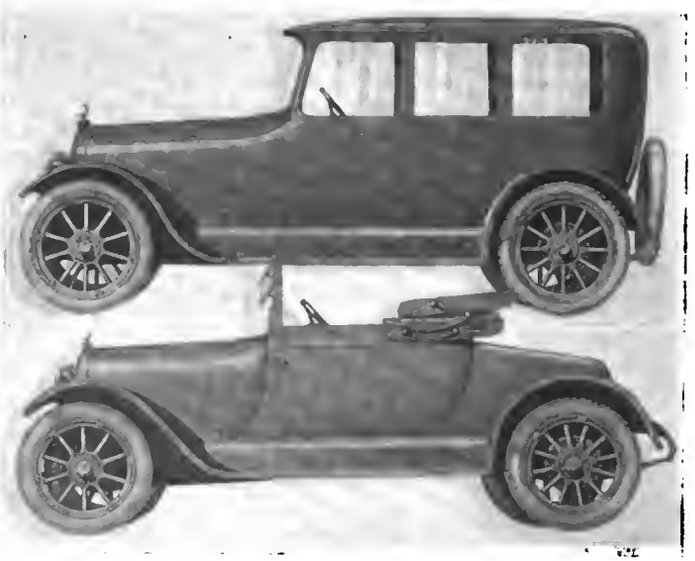
Copenhagen	500,000	Randers	24,000
Aarhaus	70,000	Vejle	15,000
Odense	45,000	Elsinore	14,000
Aalborg	40,000	Fredericia	13,000
Horsens	25,000	Svendborg	12,000

To Assemble a Car

Mammen & Drescher are preparing to assemble a car in Denmark under their own name from standard units bought in the United States. This car was designed by A. H. Anderson, chief engineer of the firm, who is now in Denmark arranging for the handling of the first 500 chassis, parts for which will be shipped to the company's shops in Copenhagen as soon as the necessary preliminaries have been attended to.

Smooth Lines in Moon Closed Models





SUPPLEMENTING the report of the new closed models brought out by the Moon Motor Car Co., St. Louis, Mo., which appeared in a recent issue of THE AUTOMOBILE the above illustrations give an idea of the smooth lines and neat finish of these cars. That at the upper left is the seven-passenger sedan mounted on the 6-66 chassis and selling for $2,250; Below it is the four-passenger coupé on the same chassis and listing at $2,150; at the upper right is a view of the sedan as a closed car, the windows and pillars being folded out of sight in the other view. Below at the right is the cabriolet design which, like the coupé, seats four, and which sells for $1,850 on the 6-43 chassis and for $2,150 on the 6-66. The interior appointments of these bodies are in keeping with their exteriors.

Many Factors in Brake Design

Tire Adhesion, Road and Wind Resistance and the Personal Equation—Brakes on Two Wheels Are Enough

By John Younger

EDITOR'S NOTE:—Paper read by John Younger, chief engineer of the truck department of Pierce-Arrow Motor Car Corp., before the Pennsylvania section of the Society of Automobile Engineers Nov. 22.

DURING the past 2 or 3 years emphasis has been laid on the accelerative ability of cars. Designers have vied with each other in getting the last fractional inch per second, per second into their performance curves. Advertising managers have not been slow in accelerating the peaks a little further and finding that the public liked it.

Get away, Pick up, Dash, Verve—I have myself called it Elan—are all familiar terms for the engineer's word acceleration. There is as yet no term of endearment for retardation. Its significance has not gripped the people's imagination, and yet of the two it is of more vital importance. The automobile death rate increases in inverse proportion to the efficiency of the retardation curve.

In fast rail traffic, with many stops, the possible retardation curve is first studied. Running a continuous stream of cars through New York subways, with an infinitesimal headway at rush hours, has caused their engineers to know almost to a fraction of a foot just where the brakes must be applied to stop at the required point at a station.

Similarly in street car work: The profit that can be derived from a set of rails in a busy district is as much a question of retardation as of acceleration. The automobile moving rapidly in and out of city traffic places, perforce, great dependence on its brakes, and actually good braking contributes greatly to the feeling of liveliness. A car with good acceleration, but sluggish retardation, does not feel as lively as one with both good.

Co-efficient of adhesion of average rubber tire, with good macadam, asphalt, concrete or brick road, 0.5.

Maximum retardation car should be capable of 10 ft. per sec. per sec.

Usual retardation for slow down or stop, 6 ft. per sec. per sec.

With pedal push a man can exert in properly designed seat, 300 lb.

With lever pull a man can exert on brake lever upward of 100 lb.

Efficiency of average brake linkage allowing for usual weak system of lubrication, about 75 per cent.

Radiation that should be provided for long hills, about 200 B.t.u. per minute per ton weight of car.

Retardation can be studied under two heads:

A—Retardation relative to the road.

B—Retardation relative to the forces acting on the car.

The primary object of the former is to slow down and actually stop the car.

The object of the second is to maintain the vehicle at a steady, safe speed, notwithstanding the forces, such as effect of gravity on a hill, that are tending toward acceleration. Both actions have special characteristics which will be taken up separately.

Tire Adhesion Figures

Obviously, the first consideration is the boundary between the car and the road—the co-efficient of adhesion or friction of the tire. This varies greatly; the shape of the tire, the nature of its tread, whether it be solid or pneumatic; the compound of rubber used, play their share in varying this; and the very fact that the road surface ranges from cement or vitrified brick to greasy mud makes us realize how impossible it is to give figures which mean anything. Curiously, pneumatic tires have a co-efficient differing from that of solid tires, the writer having found it sometimes higher, sometimes less.

George Watson, before the English I. A. E., January, 1916, gives 0.4 as the maximum adhesion of solid rubber tires on good macadam. Other authorities state that 0.6 is the figure for pneumatic tires. The writer has found an adhesion of 0.6 for solid rubber tires on cement and vitrified brick roads, and only 0.5 under similar conditions for pneumatics. The measurement of tire adhesion is, however, inextricably mixed up with that of road resistance, the number of factors entering in being exceedingly large. A convenient and accurate standard to assume is 0.5, and this is concurred in by several authorities.

I have been careful to use the term adhesion in the foregoing as specially applicable to the case where the tire does not slip relatively to the road. When the tire slips the proper term is friction. There being no relative motion between the surface of the tire and the road (the road moving back at the same speed as the tangential velocity of the car), it is obvious that the case is analogous to the body at rest on an inclined plane. The co-efficient of stiction or adhesion is greater than that of friction. Incidentally, this partly explains why a car stops more rapidly when the wheels are kept moving than when they are locked.

Road Resistance

Nature has been very good on the whole. Smooth asphalt, concrete, brick, good macadam, which offer little resistance to the passage of the car, have fortunately a good co-efficient of adhesion when dry, thus offering fair compensation. As is well known, road resistance ranges from 5 lb. to over 300 pounds per ton. It is a factor which must be considered in the study of retardation.

Wind Resistance

This may very conveniently be taken as $0.002\ Av^2$ in pounds, where A is projected frontal area in square feet, usually about twenty-five square feet. Again, this is a variable depending on wind velocity and direction. Strictly speaking, it should always be considered, but its effect is small and may

be left out in comparison with the other important items.

Possible Retardation

Given brakes on all wheels, and neglecting road resistances, we would have a retarding force of 0.5 W.

Whence from the inertia formula $F = \frac{W a}{g}$

we have the retardation $= 0.5\ g$

or 16.1 feet per sec. per sec.

The average car has, however, the brakes on the rear wheels only. Its weight is distributed equally on front and rear wheels as a rule.

The retarding force is then $\frac{0.5\ W}{2}$ and thence

the retardation is $0.25\ g$

or about 8 feet per sec. per sec.

With this latter we have that

	Stopping time.	Stopping distance.
A car going 60 miles per hour....	11 Secs.	484 Ft.
A car going 30 miles per hour....	5½ Secs.	121 Ft.
A car going 15 miles per hour....	2¾ Secs.	30¼ Ft.
A car going 5 miles per hour....	.625 Secs.	4½ Ft.

The presence of road resistance, wind resistances, and chassis losses will bring this figure of 8 feet per sec. per sec. up very closely to 10 feet per sec. per sec. deceleration, so that a car traveling at 30 miles per hour will stop in 4.4 seconds and cover about 97 feet.

Comfort in Brakes

Everyone has experienced the peculiar feeling of being shot forward in the seat when brakes are suddenly and strongly applied in railway train or street car. The eyes have not prepared the body to brace up against the action, whereas in an automobile the eyes are usually on the alert and the body is well prepared for violent retardation.

Yet, in railroad service the best stop is that recorded in March, 1914, when a Pennsylvania train experimenting with a new type Westinghouse brake stopped in 1000 feet from a speed of 60 miles per hour. This took 22¾ seconds and was a retardation of only 3.87 feet per sec. per sec.

Experience has shown that an acceleration or deceleration of 6 feet per sec. per sec. is about all that can be borne in comfort by passengers. There are naturally many who cannot even bear this, and many who can bear much more. It is interesting to note en passant the terrific velocities that man can stand, but the very small changes in it.

Extreme change, such as stoppage against a stone wall, will catapult passengers out of their seats with great violence. Six feet per sec. per sec. is on the verge of discomfort; it is, I think, reasonable to believe that 10 feet per sec. per sec. is the maximum that should be cared for. This, by the way, is equivalent to an applied horizontal pressure on the passenger of about one-third his weight. So with the chassis. The inertia effects on the body fastenings, engine and transmission fastenings are usually based on the acceleration at low speed, and this is very rarely more than 10 feet per sec. per sec., the equivalent of a 30 per cent. grade.

Four-Wheel Brakes

It is thus seen that for the average vehicle there is little to gain in putting brakes on more than the two rear wheels. It is true that they could be so adjusted that the braking friction were only half what it might be, but this is exceedingly difficult to determine and keep in adjustment, and there is real danger in excessive retardation being produced under the normal circumstances of driving over dry roads. Railroad conditions are not analogous, as a co-efficient of adhesion of 0.2 is about all that can be reckoned on against our 0.5 to 0.6 on rubber-shod automobiles.

Two-wheel brakes, provided they function properly and are used intelligently, will give all the retardation that it is safe to use. This is not, of course, the only reason why all-wheel brakes have not been adopted generally, but it is one of them.

Truck Brake Considerations

The foregoing remarks have dealt mostly with a car whose weight is distributed equally fore and aft. The passenger load is usually a small percentage of the gross weight, and there is an obvious limit to the human capacity of the space. The truck is often twice as heavy when loaded, and overloading to the extent of double the rated amount may occasionally be met with, though this evil is, I think, getting less.

There are still a few trucks whose load is more or less balanced between front and rear wheels, but they are in the minority. The load is most usually carried 75 per cent. and upward on the rear axle, and it is this the designer must pay attention to. The weight of a truck is in no proportion to its load. A two-ton truck with body may weigh 6000 pounds, or 1.5 times its load, whereas a five-ton truck with body may weigh 10,000 pounds, or equal to its load.

Each truck, therefore, must be considered individually, and the final braking effort on the circumference of the rear wheels be made equal to at least 0.5 times the loaded weight at the rear wheels. Assuming the speed of the truck at fifteen miles per hour, this will stop the truck in about thirty feet, without causing the load to pile up behind the driver's seat. This should be short enough for any board of councilmen, and should preclude the necessity for providing safety guards or fenders.

The Personal Equation

The human element in producing retardation is very great. Brakes must be skillfully applied, so that under varying road conditions the pressure is just enough to not lock the wheels, otherwise a dangerous skid might result. Women are driving cars in increasing numbers. They are unable to exert the same pressure on pedal or lever that a man can. Designers must awaken to this problem. If a light pressure is given, brakes must be adjusted more often, unless some mechanical or electrical means be supplied for assisting the human strength. As stated, this must be very delicately arranged to give perfect gradation of pressure, but the problem should not be impossible of solution.

Continuous Braking

The question of absorption of energy has been ignored in the foregoing, inasmuch as the time interval is short, and the material surrounding the brakes well capable of taking up the heat developed. On a long hill, where brakes are applied continuously, the problems that arise are different. Here there is no question of inertia effects, or of skidding, or of stopping space available; the great question is one of absorption of energy and hence radiation of heat.

At the top of a hill a car possesses both kinetic and potential energy. If at the bottom the car's speed is unchanged, then the brakes, plus the road resistance, have absorbed the potential energy. The weight of the car plays an enormous part in this, the absorption of energy being in direct proportion to it. Whilst the truck lacks the speed of the touring car, it makes up for it by weight in hill descents, and the retardation problem is the more difficult.

A Specific Hill

There are many hills 10 per cent. grade and one-half mile long. A five-ton truck, gross weight 20,000 pounds, has a gravitational component down hill approximately 2000 pounds. Assuming a road resistance of fifty pounds per 2000 pounds, or 500 pounds gross, we have a net force tending to accelerate the truck down hill of 1500 pounds.

If a safe speed of ten miles per hour is maintained the

time of descent is three min. The energy absorbed by the brakes is 1500 x 2640 ft. lb.

Or at rate of 1,320,000 ft. lb. per min.

Or 40 H. P.

Or 1700 B.t.u.'s per minute.

Take now the fact that approximately fifty pounds of metal with a specific heat of 0.12 absorb this, we have enough heat generated in three minutes (neglecting radiation) to raise the temperature of the mass from 60 deg. Fahr. to 900 deg. Fahr.

In a practical corroboration it was found there was one square foot of radiating surface from which the balancing temperature was calculated to be about 760 deg. Fahr.; the surface at the foot of the hill was certainly nearly that, being a black heat.

There are hills much worse than this in length and grade, the only salvation being the use of the engine, alternating with hand and foot brake. For the great majority of touring automobile work the normal brake is satisfactory, but for hilly and mountainous districts there is still much to be done. European designers have been well aware of this, some of the Italian designers whose testing grounds were the Swiss Alps have even gone the length of water cooling their brakes, both by drip and by waterjacket.

Auxiliary Brakes.

Only one truck, and that one of Swiss design, has attempted to solve this problem, and that by means of a device which shifts the camshaft longitudinally, converting the engine into what is really a two-cycle air compressor, the carburetor being shut off and fresh air admitted through a manifold port.

From time to time brakes working on a hydraulic principle have been devised, but always there has been the problem of cooling the liquid and insuring the tightness of pipes and joints.

It is the writer's impression that as the country roads get opened up more, and trucks are used in outlying districts, a demand will arise for a third brake for hilly districts. This will enable the vehicle to coast down a long incline at a predetermined safe speed, with no wear and tear on the engine or undue heating of the brakes.

Discussion of the Paper

At the meeting the chair was taken by B. B. Bachmann, and although the attendance was not very large it was obvious that every member present was very keenly interested in the paper. The discussion was opened by A. Ludlow Clayden, engineering editor of THE AUTOMOBILE, who took up the subject of brake materials, asking whether Mr. Younger had any data with respect to their relative qualities. He pointed out that the usual kind of brake lining is a fairly good heat insulator which means that most of the heat generated in the brake has to be dissipated by the drum since the brake band or shoe is to some extent insulated by the lining. He said that metal brake surfaces were still the most extensively used in Europe and that all kinds of materials had been tried. Cast iron is the most usual but phosphor bronze has been used, and one brake for which great claims were made had the shoes faced with alternate sections of different materials. Trials were made with half the brake surface cast iron in sections about 2 in. by 2 in. and the other half phosphor bronze, white metal, aluminum, and, finally, compressed asbestos fabric.

The last time the speaker had any information from Europe regarding this brake the cast iron and fabric segments were proving very satisfactory, it being stated that the bonding material in the fabric seemed to spread a little over the iron, preventing rust. Also, it was said that the brake operated without the scrape usually associated with a plain iron brake.

Another point which is not often appreciated is the great theoretical advantage of diagonal braking. This consists of having brakes on all four wheels, so connected that one control operates the right front wheel and the left rear wheel simultaneously, the other control operating the other pair. The object of this layout is that as soon as either the front or rear wheel ceases to revolve it loses its power to direct the line of motion of the car. If both back wheels or both front wheels are locked the car is unsteerable, but with diagonal linkage it is possible to lock one pair and still have one wheel on each axle rolling freely and therefore available for steering.

The disadvantages are purely mechanical, the link system becomes very complicated and the brake is costly.

L. Goldmerstein, editorial staff, *A. S. M. E. Journal*, supported Mr. Younger's contention that it would be essential to have two sorts of brakes, one intended for rapid stopping and the other for the descent of long grades. He described a possible form of brake with which he has been experimenting wherein power is absorbed by a reciprocating piston which draws oil into a cylinder and then expels it through a small valve, the lift of which is controllable. This raises the temperature of the oil and the heat can be dissipated by any convenient means. One way he suggested was to extract the heat by making the oil do work such as the driving of a fan.

Regarding the conductivity of linings, this undoubtedly was very poor but the most remarkable fact was that the conductivity decreased as the intensity increased. The soft linings were much better conductors than the hard ones. This doubtless was due to the action of the air which would be contained in considerable quantities between the meshes of the softer fabrics.

Truck Brake Requirements

E. R. Whitney, chief engineer, Commercial Truck Co. of America, said that in designing brakes for trucks it was essential to make them so that a considerable effort was required to apply them. At one time he said his company had fitted a brake of exceptional power and discovered very quickly that truck drivers were using it so viciously that severe damage was being done to the mechanism generally

In his reply Mr. Younger said that he agreed entirely with the last speaker and that he had discovered a brewery truck driver, whose services he had enlisted for the purpose of experiment, was able to exert a pedal pressure of 400 lb. Regarding brake materials, it was undoubtedly a fact that the usual linings were good insulators and this he thought accounted for the rapid wear on brake drums with cars used in mountainous districts. He pointed out that with an internal and an external brake on the same drum all the radiation from the drum is limited to its inner edge and said that he had known a case where the drum had got so hot that it had parted all around the edge, the ring separating from the disk. Cases where the spokes of a wood wheel had been blistered were also not uncommon. Up to the present he had not been able to find any material better than cast iron for facing the shoe of the propeller shaft brake on a truck.

Drum Surface a Factor

One important thing which seldom received any consideration, was the nature of the surface of the brake drum. Evenness of wear he said was affected profoundly by the nature of the surface when the drum was new. If the brake drum is merely turned it is left covered with minute but very sharp points and these exert an unnecessary cutting action on the shoes or band. If the surface of the drum is ground to a fine polish the surfaces will last longer.

Concerning Mr. Goldmerstein's remarks about the conductivity of fabric, this explained something which he had noticed and which had puzzled him. This was that the softer linings appeared to suffer less from prolonged heating, as in the descent of a mountain, than did the heavily compressed fabric, although the latter was much more durable in ordinary stopping service where long grades were not encountered. After prolonged heating, the compressed fabric appeared liable to disintegrate in some way.

Alcohol—The Fuel of the Future

Enormous Demand for Gasoline Makes Alcohol and Benzine Potential Developments for Automobile Engine Fuel—Utilization of Wood Waste Offers Vast Supply

By Bernard N. Glick, M. Sc.

EDITOR'S NOTE:—As previously pointed out by Mr. Glick in his article on the manufacture of gasoline from casing-head gas, the increasing demand for gasoline for automobile fuel renders the development of other fuels imperative. In this article the author reveals many interesting possibilities in the production of alcohol and benzine suitable for fuel purposes, dwelling especially on the enormous supply of wood waste as a source of alcohol.

WITH approximately 3,000,000 motor vehicles doing duty in the United States, from 1,000,000,000 to 1,200,000,000 gal. of gasoline have to be provided annually to keep them running. There are unmistakable signs that the production of this enormous volume of gasoline will become increasingly difficult and as a consequence there is in the minds of many automobile engine students the vague thought that gasoline, while the fuel of to-day, may have to give way to some other product to-morrow. In this connection it is comforting to know that there is a substance already well known, which can take the place of gasoline and run these automobiles just as efficiently, and perhaps more so.

The substance that thus stands out predominantly as the fuel of the future is alcohol. This product has long since passed the stage where its suitability was questionable, the only thing retarding its adoption being its high price, due to the raw materials now used and the limited use to which it is put at present. With a growing demand, such as will arise when the price of gasoline becomes abnormally high, we anticipate a search for cheaper methods of production and for raw materials which will give it in sufficient amounts to meet the enormous demand that will exist for a suitable fuel for internal combustion engines.

The question of the suitability of alcohol as a source of power in internal combustion engines has been sufficiently established by long series of tests conducted by various groups of experimenters. The United States Bureau of Mines has done magnificent work in this direction and many of the following figures comparing gasoline and denatured alcohol are taken from the results of their painstaking efforts to help solve the fuel problem of the future. Although the calorific power of alcohol is little more than one-half that of gasoline —about 11,160 and 20,900 B.t.u. per lb. respectively—its greater efficiency—alcohol 28 per cent; gasoline 16 per cent—compensates for this. This higher efficiency of alcohol is due to various causes, chief among which are the following:

Less Air Required

1—The volume of air required for complete combustion of alcohol is only about one-third that required by gasoline, and thus much less energy goes away in the exhaust. Moreover, this smaller dilution with air enables a more perfect mixture to be formed with consequent more perfect combustion.

2—The alcohol-air mixture can be safely subjected to pressures of 200 lb. per square inch without spontaneous ignition, whereas the safety limit for gasoline is 80.

3—All mixtures of alcohol and air containing from 4 to 13.6 per cent of alcohol are explosive, whereas the explosive range for gasoline is from 2 to 5 per cent, necessitating much more careful carbureter adjustment.

4—The combustion products of alcohol are smokeless, almost odorless, and do not clog up the cylinders and valves.

Gasoline for Starting

The only serious difficulty encountered would be the starting of the engine in cold weather and this could be provided for by carrying a small auxiliary gasoline tank to be used in starting.

Raw Materials Abundant

The possible raw materials for alcohol production are unlimited, for anything containing starch, cellulose or sugar can be utilized. In the case of starch we are limited at present to established crops, and the cost of the raw material from such substances as potatoes, maize and rice includes raising the crop, harvesting it, transportation to the distillery and the final conversion there to alcohol. As a consequence the cost of the raw material is too great, varying as it does from 12 to 25 cents per gallon of finished alcohol.

With cellulose and sugar we are able to make use of by-products of other industries where all the above charges are rightly charged to the main industry, and so with the cellulose waste of the lumber industry, finished alcohol can be produced under present conditions at from 13 to 19 cents per gallon, and from the sacchariferous waste of the sugar industry at approximately 15 cents a gallon.

Around the forests, the fields and sawmills of this country there are millions of tons of waste material now allowed to rot or burn, to get rid of what is in many cases considered a nuisance. Various forms of vegetation, which with the aid of the chemist could be rendered valuable sources of fuel supply, are allowed to die, having served no useful purpose during their existence.

Wastes from paper mills, comprising millions of gallons of liquor containing sufficient fermentable matter to be worthy of exploitation, are allowed to pour into the rivers, impairing their beauty and constituting a menace to the fish in them.

Crops of all sorts, corn, maize, oats, barley, potatoes, rice and many others could be increased and exploited to produce alcohol as a fuel, while the sugar industry could furnish thousands of tons of refuse material eminently suitable for its further production.

Lumber Waste a Vast Supply

Of all the above possible sources, the most interesting, owing to the low cost of raw material, is the waste from the lumber industry, particularly that in the form of sawdust or small chips. This material in the vicinity of sawmills or woodworking plants is often an item of loss owing to its

production in excess of their own power requirements, its value never rising above 50 cents per ton, even when used as a source of power. The disposal of this superfluous waste from figures gathered by the Forest Products Laboratory at Madison, Wis., costs from 30 to 66 cents per cord of 1800 lb., the total annual loss from this cause amounting to about $6,000,000 annually, in addition to the value of the wood so burned. This represents an annual wastage of approximately 15,000,000 cords of wood and constitutes only about 50 to 60 per cent of the total waste material produced in this form. Thus we see that there is produced annually in the United States waste material amounting in volume to about 30,000,000 cords, or around 27,000,000 tons, which is now burned as the easiest method of getting rid of it.

Wood Alcohol Useless as Fuel

From experiments which have been carefully conducted by various experimenters, a ton of dry sawdust has been found to yield with proper treatment around 20 to 25 gal. of 95 per cent alcohol (ethyl or grain alcohol, not wood alcohol, for this latter is useless for fuel purposes owing to the formation of products of combustion which would wreck the cylinders) and we could have therefore an estimated production from this source alone of around 500,000,000 gal. annually. If we add to this the amount of wood wasted in the form of stumps and branches sufficiently thick to be barked, which on a conservative basis is equal in amount to the sawdust and chips produced, we would get from this "waste" wood a volume of alcohol almost sufficient to supply with fuel even the stupendous number of automobiles at present in use.

Process Now Used

The process now used for the production of ethyl alcohol from wood consists first of all in hydrolyzing the hogged and shredded waste with dilute sulphuric acid at a steam pressure of about 60 lbs. for a short time. This is done in rotary digestors, made of steel boiler plate with an acid proof lining to insure a thorough mixing of the wood and acid. In this operation a portion of the wood is converted into a mixture of sugars, some of which are fermentable. The digested mass is then transferred to a diffusion battery where the sugar and other soluble material is extracted. The acid extract is neutralized with lime or limestone. and a heavy sludge of calcium sulphate is formed, leaving a neutral sacchariferous liquor on standing. The clear solution is drained off and fermented with yeast, and the alcohol produced separated by fractional distillation and rectified in the ordinary way.

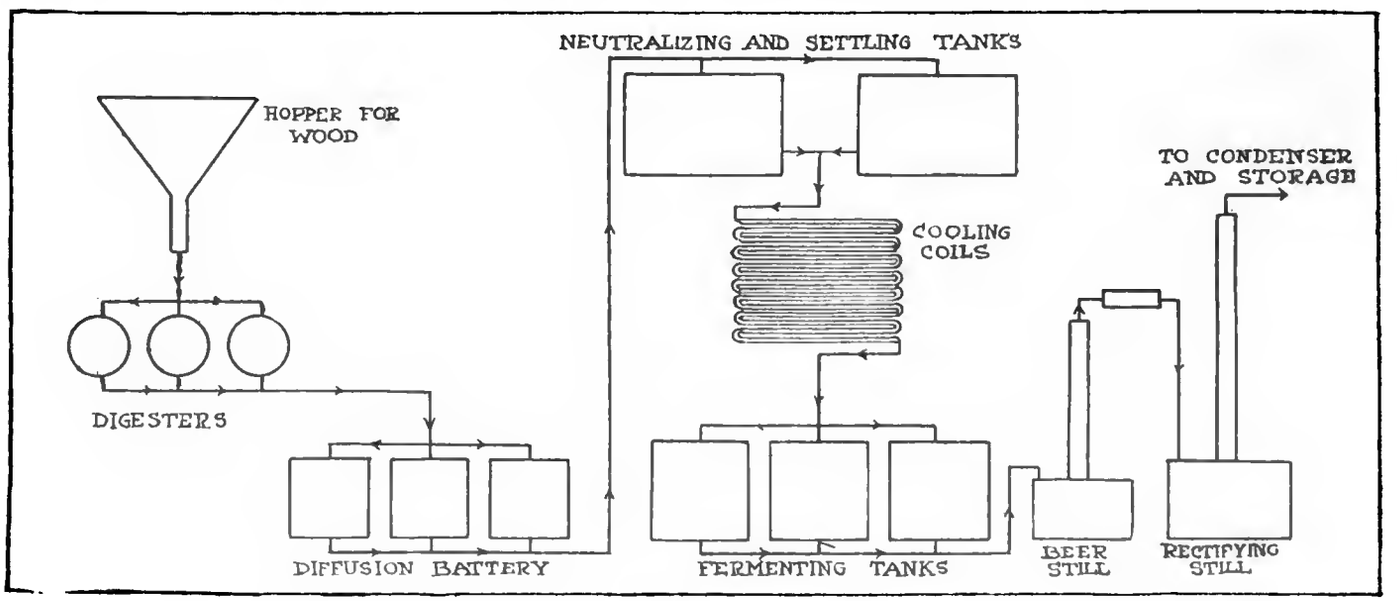
History of Early Work

The first known attempts to produce sugar from vegetable matter were those of Braconnot in 1819, and since that time many have worked, experimental plants have been built and operated, all to meet with failure owing to lack of scientific and engineering knowledge. In 1898 Simonsen published the results of his investigations using very dilute sulphuric acid as the hydrolyzing agent and claimed to have got an amount of alcohol equivalent to 6 per cent of the weight of dry wood used. A small plant was built in Christiania to try out his process but failed owing to the extreme dilution of the acid used, thus making the handling of the large volume of liquor produced uneconomical.

Some time later Classen developed a process in which sulphur dioxide was used as the hydrolyzing agent. This process is interesting for it marked the beginning of the development of this industry in America, for the American rights of the Classen patent were acquired by a Chicago concern in 1903, which, after experimenting, erected a plant at Hattiesburg, Miss., costing about $250,000 to operate on longleaf pine sawdust.

Process Successful if Correctly Used

This plant was a failure for a number of mechanical and technical reasons. Ewen & Tomlinson, who were associated with the Classen enterprise, then struck out on their own and after experimenting with sulphur dioxide in different forms as a hydrolyzing agent, finally abandoned it and went back to dilute sulphuric acid. They erected a plant at Georgetown, S. C., which was later acquired by the DuPont Powder Co. who operated it intermittently until the sawmill in connection with the plant was burned in 1913. While a new mill was being erected they devoted a considerable amount of time and money to research on the problems involved and the result is evidenced by the fact that they are now producing over 2,000,000 gal. per annum of absolute alcohol at a nice profit. Other plants have been built in the west by men without knowledge of the requirements of the process and without adequate technical supervision, and have met their inevitable fate. In fact, as long as the development of this process, which requires the highest type of engineering and chemical skill, is left in the hands of men



Diagrammatic layout of a plant for the manufacture of alcohol suitable for automobile fuel from wood waste

of the stock promoting type, the various attempts made will be failures.

Cost of Production

The Forest Products Department, Madison, Wis., has got up as the result of its experiments, an estimate of the cost of production which is given below. The estimate assumes a yield of only 20 gal. of alcohol per ton dry waste, costing 40 cents per cord of 1800 lb. and a location where the supply of waste is uniform and constant for a period of 20 years, with good water facilities and a fairly close supply of sulphuric acid and lime. In such a place, a plant properly designed and constructed, of 2500 to 3000 gal. daily capacity, will yield alcohol of 95 per cent purity at a cost of 13.7 to 19.5 cents per gallon. These figures certainly seem to justify their serious consideration by lumbermen and capitalists, for there certainly seems to be all the necessary factors for successful exploitation here. Some impetus is required though, to get things started and, as stated above, that impetus will surely come when gasoline sticks too long at an inordinately high figure.

The tests and results referred to were for engines designed for the use of gasoline as a fuel, the use of alcohol not having been considered. Were this done, however, and engines capable of taking advantage of the various factors favoring alcohol used, particularly taking into account the greater efficiencies possible, using an engine capable of working at compressions up to 200 lb., it is very likely that after as much time and study had been devoted to perfecting such engines as has been hitherto devoted to those using gasoline, a comparison even more favorable to alcohol might be the result.

Numerous other tests have been performed using mixtures of alcohol with other substances, the most important being benzine. It has been found that such mixtures are superior to either alcohol or benzine used separately, the most effective mixture being that formed by mixing one part of alcohol with one part of benzine. As evidence of this two series of tests may be quoted.

Germans Use Alcohol

In Germany since the war began a considerable shortage of gasoline has developed and substitutes had to be devised. Alcohol is fairly plentiful there, being made from potatoes, while benzine is recovered in a very thorough manner from their by-product coke ovens. It was natural then that they should turn to these for a gasoline substitute. From a series of tests with a Mercedes car of the 1914 touring model having an ordinary carbureter, the following results were obtained.

Fuel	Speed per Hr. (Miles)	Distance Covered on 1 Pint Fuel (Miles)
Gasoline	44	3.60
Benzine	42	3.79
1 pt. benzine 1 pt. alcohol	42	4.66
1 pt. benzine 2 pt. alcohol	41	4.47
1 pt. benzine 3 pt. alcohol	39	4.34
1 pt. benzine 4 pt. alcohol	38	4.10
1 pt. benzine 5 pt. alcohol	36	3.72

Difficulty was encountered in starting the car on the above mixtures and this was overcome by carrying a small auxiliary tank containing gasoline for use in starting. The mixture of alcohol and benzine in equal proportion was found to be decidedly superior to gasoline, and calculated at before-the-war prices, was more economical, too.

W. T. Ormandy ran a series of similar tests on a four-cylinder Maudesty engine (90 by 130 mm. with compression space about 25 per cent of total cylinder volume) and expressed his results as follows:

Fuel Used	Power Gasoline = 100	Volume of Fuel Used Gasoline = 100
Benzine	98.25	84.5
1 benzine 1 methyl sp	99.0	96.3
1 benzine 2 methyl sp	92.0	108.9
1 benzine 3 methyl sp	91.5	124.5

Sp. gr. gasoline 0.710. Sp. gr. meth. sp. 0.815. Benzine used 90 per cent. Sp gr. 0.885. Engine run at 1000 and 2000 r.p.m.

These tests are typical of a number of others and show that mixtures of alcohol and benzine make eminently suitable fuels for even engines built to use gasoline, and that were it possible to produce sufficient benzine the most favorable mixture would be that containing equal amounts of the two.

Possibilities of Benzine

Benzine has long been known as a possible automobile fuel and it is ready to step into the breach as far as possible. The chief factors militating against its use alone are first of all, the unfortunate fact that it solidifies at 5.4 deg. Cent., or 41.7 deg. Fahr. and would thus be useless in cold weather and, secondly, that the maximum possible production at present is about 100,000,000 gal. annually or less than 10 per cent of the amount of gasoline now used. This is not because more could not be produced, for the raw material, coal, is here in abundance, but is due to the fact that only a small percentage of the coal burned annually is burnt in such a way as to allow of the recovery of the benzine from it. If the coal consuming public could be educated to the use of coke for heat and power production, thus allowing of the burning of coal at central stations, as is now being suggested in England, with the recovery of all the by-products, coal gas, benzine, toluene, carbolic acid, naphthaline, creosote anthracene, etc., that now go up in smoke, there could be produced sufficient gas to materially reduce its present price to consumers, benzine enough to use in conjunction with alcohol to replace gasoline and still enough left over, along with the other products, to put the budding American dye industry on a firm independent footing.

Before the war benzine was selling in the neighborhood of 17 cents per gal. and would therefore reduce if anything the price of alcohol with which it were blended. The raw materials for both these, wood and coal, exist here in abundance, both could be obtained as by-products of some other industry, and both at present are produced in insignificant amounts, owing to the lack of initiation and enterprise that are necessary for their production in worth while amounts. If properly developed to their fullest possible extent they would effectively lay the ghost of the failing gasoline supply.

Piston Progress Illustrated

The advance in piston design made in the past five years is brought out strikingly in the two pistons illustrated above. That at the left was used in the six-cylinder Oldsmobile Limited for 1911 and 1912. It was of cast iron and weighed 6 lb., 14 oz. That at the right is the 9 oz. aluminum piston used in the new eight-cylinder Oldsmobile.

Constant Pressure Cycle Truly Efficient

Criticisms of Suggestions Founded Upon Unsound Basis—A Reply to J. L. Napier

By Arthur B. Browne and Herbert Chase

THE criticism written by James Langmuir Napier entitled "The Truth about the Constant Pressure Cycle," which appeared in the August, 1916, issue of *The Automobile Engineer*, and was reprinted in THE AUTOMOBILE, attempts to promulgate so many half truths and contains such wholly unwarranted attacks upon statements made in papers read before the (American) Society of Automobile Engineers and the (British) Institution of Mechanical Engineers, that we cannot permit it to go unchallenged.

Holding up to ridicule what he terms a "quasi-scientific" statement made by Mr. R. M. Neilson,* a former associate of Mr. Dugald Clerk and a member of the Institution of Mechanical Engineers, and charging "neglect of elementary principles" in our paper entitled "Possibilities of the Constant Pressure Cycle," Mr. Napier proceeds to ignore every detail and refinement of the proposed constant pressure cycle save those which, by wholly impracticable comparisons, could be made to subserve his own arguments. He then closes with a diatribe against a "burner" which by actual operation, under conditions more exacting than those of its application to a reciprocating engine, is daily proving the superficiality of his judgment. In order that the truth may prevail we offer the folowing:

*The reference cited was taken from a paper entitled "A Scientific Investigation Into the Possibilities of the Gas Turbines" which was presented in October, 1904, before the Institution of Mechanical Engineers, of which Mr. Neilson was then an associate member. Among those who discussed Mr. Neilson's paper were Mr. Dugald Clerk, Prof. F. W. Burstall, Mr. James Atkinson, Col. R. E. B. Crompton, C.B. These gentlemen would hardly have allowed Mr. Neilson's figures on the constant pressure cycle to go unchallenged if they were not well founded in fact.

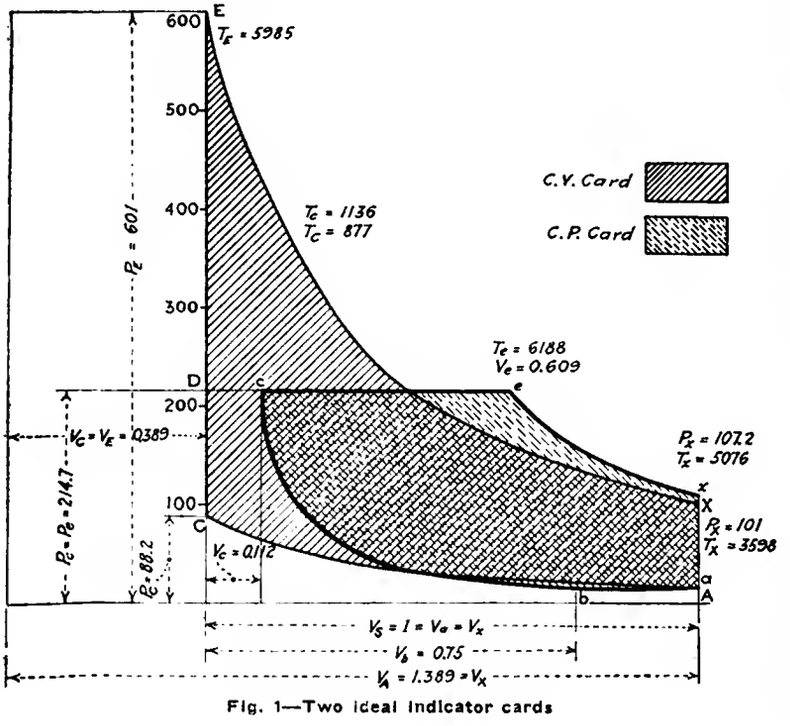


Fig. 1—Two ideal indicator cards

Engines operating upon the constant volume cycle have practical limitations of compression pressure, owing to preignition difficulties and high maximum pressures which do not occur in engines of the proposed constant pressure type.

In the proposed constant pressure cycle the thermal efficiency increases as the load decreases, a most important condition not found in the constant volume cycle.

The proposed cycle renders practicable the utilization of exhaust heat by which means its ideal efficiency is rendered higher than that of any cycle now in use, a fact entirely overlooked by our critic.

The proposed constant pressure cycle is so well adapted to a two stroke cycle that its power output may be made greater for a given bore and stroke than that of the constant volume cycle whether the latter operate on a two or four stroke cycle.

Engines operating upon the proposed cycle are readily adaptable to the use of the heaviest and cheapest liquid fuels which are wholly unavailable in constant volume engines.

The proposed cycle provides means for proportioning the negative work to the work of the cycle. This permits of its use under widely variable loads and enables use of a variable cut-off without throttling.

The proposed cycle also permits of manual modification of two dimensions of the P V diagram. It is thus more flexible than the constant volume cycle.

These conclusions are best proved to practical engineers by comparing the cycles in engines of equal bore and stroke. With petroleum fuels so largely used in modern constant volume oil engines, a compression pressure much is excess of 75 lb. gage is seldom used because of the danger of preignition. Hence an absolute pressure of 6 atmospheres (88.2 lb.) is taken for the purpose of comparison as representing a rather high average. As opposed to this a compression pressure of 200 lb. gage is taken as being a very conservative value for an engine of the constant pressure type, since no serious structural consideration can be advanced against maximum pressures so far below those inherent in the constant volume type. To compare, as does our critic, engines using equal compression pressures is as impracticable as is the comparison of a Diesel engine with one of the constant volume type, using Diesel compression pressures. The constant volume oil engine is necessarily a low compression type while the constant pressure engine is essentially a relatively high compression type.

The two ideal cards shown in Fig. 1 are drawn to scale using strokes of equal length, the compression pressures mentioned above, and starting compression from one quarter stroke in the case of the constant pressure card. That the unloading valve specifically described in our paper provided means for automatically starting the compression at any point of stroke desired, was a point conveniently overlooked by Mr. Napier. The table given herewith shows the varying work areas and efficiencies obtained in other ideal cards with different compression pressures and with compression starting from different points of stroke.

From this table it is at once evident that the ideal efficiency of the constant pressure cycle increases rapidly as the load decreases. In the constant volume cycle the *ideal* efficiency remains constant at all loads but in practice it is a well-known fact that the *actual* efficiency decreases very rapidly as the load decreases. At light load the actual efficiency may fall below-one-tenth that at full load.

As to the question of efficiency, the figures given prove conclusively that in this particular the proposed constant pressure cycle under the conditions outlined has a decided advantage over the constant volume cycle when the saving resulting from the perfectly feasible use of a portion of the exhaust heat* is taken into consideration. Entirely practicable means for such utilization were clearly shown in the description and diagram of the proposed engine. Since the saving in heat thus obtainable will render the ideal efficiency from 25 to 80 per cent higher *than it would otherwise be*, how utterly worthless are the conclusions reached by our critic when he deliberately disregards this saving and then uses this faulty premise as a basis for redicule! In fact if substantially the same arguments advanced by our critic had been carried to a logical conclusion he would have proved that the efficiency of the Diesel engine is less than that of the constant volume type of engine, whereas we know from long experience that the reverse is true.

The table and cards given herewith show that the net work areas are somewhat less for the constant pressure than for the constant volume cycle. The difference is however almost nil if a somewhat higher compression pressure be taken than that assumed in the constant pressure card shown. This higher pressure *cannot be* used in practice in the *constant volume* cycle without involving difficulties (such as pre-ignition and exceedingly high explosion pressures) not encountered in the constant pressure type.

Furthermore the constant pressure engine lends itself readily to a two stroke cycle. Its power output *per stroke* in this type is substantially the same as in the four stroke type. Hence when running two cycle the power output of a constant pressure engine is greater than that of a constant volume engine of equal bore and stroke, whether the constant volume engine run two cycle or four cycle.

It is a well-known fact that the two stroke constant volume or Clerk type of engine has a power output *per stroke* which is little more than half that per stroke in the four stroke type. This is due in part to difficulties in scavenging without loss of fuel. On the other hand, in the two stroke constant pressure type, running as it does with practically zero clearance, the scavenging may be made nearly perfect, and this without any loss of fuel, since the latter is not added until the beginning of the working stroke. On this basis our contentions that the power per unit of weight of a constant pressure engine may be made greater than that of a constant volume engine of equal bore and stroke, and that for this and other reasons the engine is better suited for automobile propulsion

(*Continued on page* 948)

*Mr. Neilson, in obtaining the figure of 84 per cent ideal efficiency quoted in our paper, contemplated saving a large proportion of the heat in the exhaust gasss.

Table I—Comparative Data for Two Automobile-Engine Cycles

Item No.	CONSTANT-VOLUME CYCLE		PROPOSED CONSTANT-PRESSURE CYCLE							
	Symbol	Num. Value	Symbol	NUMERICAL VALUE

EXPLANATION OF SYMBOLS USED IN TABLE I

The results given in this table are purely theoretical and apply only to ideal cards. The C. P. cycle figurss given in Fig. 1 refer, as will be readily seen, to the calculations made for the third column of figures shown under the heading "Proposed Constant Pressurs Cycls." All pressures in the table ars given in pounds absolute and the temperaturs in absolute degrees Fahrenheit. The comparison between the two cycles is for engines of equal displacement with a stroke of 1 ft. and a piston area of 144 sq. in. Exhaust is assumed to take place at the end of the stroke. Certain assumptions have been made in calculating these results. These ars explained in the following paragraphs, the figures given at the left referring to the corresponding number under the heading "Item No." in Tabis I.

1. Both the pressures are assumed; $P'a$ is the initial pressure for the C. V. cycle and Pb is the pressure at the start of compression for the C. P. cycle.

2. Stroke volume is assumed as unity for both cycles. It will be noted that in the C. P. cycle this volume (Va) includes Vc, the volume of the point where delivery to the receiver begins, there being no clearance in the cylinder.

3. The volume $V'a$ is the total cylinder volume and equals also the exhaust volume for the C. V. cycle.

4. Compression and expansion are assumed to be adiabatic. In the C. P. card the unloading valve remains open from a to b, so that the compression (above atmosphere) starts at b. Also $Pc = Ps$ are the pressures at the end of compression and at cut-off respectivsly.

6. For the C. V. cycle $V'c$ is the volume at both the end of compression and the start of expansion. For the latter $V'c = V'e = V' \div [1 - (P'c \div P'e)]^{0.71} = Ve$. The volume at the end of compression (Vc) equals $Vb\,(Pb \div Pc)^{0.71}$.

7. The constant R for the C. V. cycle is $P'a\,V'a \div T'a$. For the C. P. cycle $R = Pb\,Vb \div Tp$.

8. $T'c$ and Tc are the temperatures resulting from adiabatic compression. $T'c = P'c\,V'c \div R$ and $Tc = Pc\,Vc \div R$.

9. Heat added in C. V. cycle is assumed to be that resulting from complete combustion of a quantity of fuel having a weight equal to one-fiftsenth the weight of air present. Calorific value of fuel is assumed to be 18,000 B.t.u. per lb. In the proposed C. P. cycls a portion of the heat added is recovsred from the exhaust gases. (See note 18.) H and h ars expressed in British thermal units. $H = 18{,}000$ wt. area $\div 15$ and $h = 1200\,Mb$.

10. Wsight of gas hsatsd in C. V. cycle includes products of combustion rsmaining in clearance space, the specific weight of which is *assumed* for convenience to equal the specific weight of air, approx. 0.076 lb. per cu. ft. at 60 deg. F. and 14.7 lb. abs. pressure. In the C. P. cycle gas heated is all air in a cylinder with zero clearance-volume. The volums of gas heated is controllsd at will by varying point of cut-off. $M'a$ and Mb ars the pounds of gas and air respectively heated. $M'a = 0.076\ V'a$. $Mb = 0.076\ Vb$.

11. For convenience in figuring, $T'e$, Te and he (see note 19) ars determined on the *assumptions* (a) that the specific heat of ths products of combustion is the same as the specific heat of air, and (b) that the specific heat remains constant throughout the temperature range. The specific heat of air at constant volume is taksn as $Kv = 0.1689$ and at constant pressure $Kp = 0.2375$. Ths temperature of expansion ($T'e$) equals $T'c + (H \div M'a\,Kv)$. The temperature of cut-off (Te) equals $Tc + (h \div Mb\,Kp)$.

12. Whils $P'e$ is high in the ideal card, its actual value in practice is known to bs much lower than 600 lb. Pc, the maximum pressure attained in the C. P. card, can be controlled at will by simply varying ths prsssure on the unloading-valve spring. The explosion pressure is $P'e = R\,T'e \div V'e$.

13. The volume at cut-off (Ve) in the C. P. cycle equals $Te\,R \div Pc$.

14. $P'e$ and Pe will both be much lower in practice than the theoretical value noted. Ths pressurs of exhaust in ths C. V. cycle ($P'e$) equals $P'c\ (V'c \div V'e)^{1.4}$. For the constant pressure cycle $Pe = Pc\ (Ve \div Ve)^{1.4}$.

15. The theorstical values of $T'z$ and $T'e$ (as well as $T'e$ and Te) are also much higher than in practical engines. The temperatures of exhaust for C. V. and C. P. cycles are respectivsly $P'z\,V'z \div R$ and $Pe\,Ve \div R$.

16. Ths gross area is the total area undsr upper lines of respective cards. The gross arsa of the C. V. cycle is $2.5\ (P'e\,V'e - P'z\,V'z)$. For ths C. P. cycle it is $Pc\,Ve + 2.5\ (Pc\,Vc - Pz\,Vz)$.

17. Negative work is the work of compression in C. V. card and work of compression and dellvery in C. P. card. Ths negative area for the C. V. cycle is $2.5\ (P'c\,V'c - P'a\,V'a)$ and for the C. P. cycle is $Pc\,Vc + 2.5\ (Pc\,Vc - Pb\,Vb) + Pb\ (Va - Vb)$.

18. In the third C. P. card the net work is close to its maximum value when $Vb = 0.75$, hence little is gained, with 214.7 lb. compression pressure, by starting to compress sarlier and by cutting-off later. The net work area for ths C. V. cycle is $W'g - W'c$ and for the C. P. cycls $Wg - Wc$.

19. Piston area = 144 sq. in. One B.t.u. = 778 ft. lb. hz is detsrmined by assuming that the exhaust gases will heat the air supplied to a temperature midway between Tc and Te. The heat recovered from the exhaust (hz) in the C. P. card equals $0.5\ (Te - Tc)\ Mb\ Kp$.

20. Thermal efficiency is the ratio of net work dons to *net* heat added by fuel. The C. V. thermal efficiency is $144\ W'n \div 778\ H$. For the C. P. cycle e equals $144\ Wn \div 778\ (h - hz)$.

21. Ths mean effective pressures equal $W'n \div V'e$ for the C. V. cycle and $Wn \div Ve$ for the C. P. cycle.

The Automobile and Truck Industry In Switzerland

War Has Exerted Marked Effect on the Country—Occupations of People Greatly Changed—Many Plants Have Turned to Motor Vehicle Construction—Sales Opportunities

By E. A. Langdon

ALTHOUGH not involved in the world war, Switzerland, like many other neutral countries in Europe, has been doubly busy since August, 1914. The effects of the war are very clearly visible on life in Switzerland, which is surrounded on all sides by belligerents; and, while officially this Helvetian republic is identically in the same situation as during the first six months of 1914, as a matter of fact the past two and one-half years have witnessed striking changes in the life, occupation and methods of work and business of the people of Switzerland.

To begin: There has been considerable change in the occupation of the people. Before the war a great division of the nation was kept busy attending to the many tourists who visited the country. These people were reduced to idleness almost immediately by the outbreak of the war. Then there were a great many industries, such as lace making, which from the first day of the war on found it difficult both to dispose of the products and to obtain new raw materials for carrying on the work. Thus, thousands of people were forced to look for a different mode of occupation.

Practically No Car Imports

As for importing automobiles into Switzerland, this trade is at present practically nil, because there are sufficient facilities for making all the machines the country requires. Moreover, any merchant wishing to import automobiles would find this a very difficult matter, and practically impossible, for he would be required to furnish a more than ironbound guarantee that the vehicle would in no way be made serviceable, directly or indirectly, to the Central Powers. This is, at the present involved state of Swiss industries, almost an impossibility, because the bulk of Swiss industries are occupied with war contracts of some kind or other, and, all denials to the contrary notwithstanding, the relations between manufacturers supplying the Allies and those working for the Teutons are extremely amicable; hence, the country being anything but divided along lines of the two sides in the war, it would be very difficult to promise that a machine would never be used by someone tied up with the opposite belligerent.

However, while, as just stated, there is practically no importation of automobiles into Switzerland, it is safe to prophesy a considerable trade of this nature for the post-bellum period. The reasons are:

Modernization Going On

Switzerland is being modernized by the war more than it was during the twenty-five years preceding it; industry will be much enhanced; modern ideas will enter the minds of the people, who up to a short time ago were still, in some ways at least, rather conservative. Such a development cannot help creating an increased demand for automobiles. The machines required will have to be well adapted to the peculiar local conditions of this alpine country; the cars will have to be built with low center of gravity, good hill-climbing ability, and a view to the greatest possible fuel economy; they will have to be medium-priced, light, and strong; they will have to be covered by a reliable maker's guarantee; the purchaser will require the presence, within a few hundred miles, of a supply station of reserve parts; the machines will be expected to have complete equipment; they will be easier to sell if they are fitted with large-size tires; they will, considering the standard of quality, have to compare well with French and German makes, which are well known in Switzerland, and which, even if a little dearer, will be given preference in many instances—other things being equal; in short, American automobile makers working for Swiss business will have to win the confidence of the shrewd population of that country.

A Cosmopolitan Center

It would seem, perhaps, that the results of such endeavors could never be proportionate to the efforts, because of the small size and population of the country. This is, however, a very narrow view to take of the situation. In normal times Switzerland is a meeting ground of all Europe, at least at certain times of the year; and an automobile displayed and doing good work in Switzerland serves to advertise one's products to Danes, Poles, Russians, and inhabitants of the Balkan territories. There is nothing which counts as much in European eyes as "the proof of the pudding," and the work of a machine which stands up well under the strenuous requirements of Swiss touring is bound to impress a prospective buyer of automobiles.

In one respect Swiss business is much easier than in other continental countries. Due to the intense contact with foreigners, the number of Swiss who have a command of English is surprisingly large, and it is hardly necessary for a salesman to speak the native language of the particular section of Switzerland he visits.

A Good Light Car Market

It is also possible that after the war there may be a pretty good market for light automobiles, specially suitable for doing occasional dairy work, which can be jacked up and connected to a separator or such implements. As to plowing machines, hoes, etc., the industries requiring such machines are so small that it would hardly pay to carry on a sales campaign for the introduction of such machinery.

All in all, there is no doubt that Switzerland, too, will be a much more important market after the war than before.

The Call for Cars

Speaking of the call for automobiles: The demand from belligerent countries requires no further elucidation. All belligerent nations are anxious to get into their possession as much automobile equipment as possible. Money is no object. The requirements in Switzerland are also created directly by the war. The first circumstance calling for

automobiles is that the supply of freight cars on Swiss railroads is none too ample to transfer the much-increased output of the nation's industries. Motor trucks are needed. Furthermore, there is also an increase of passenger traffic, and while it is almost impossible to obtain statistics at present, when the figures will once be given out they will in all likelihood exceed the foreigners' traffic of peace times. Everyone knows what these remarks refer to. Switzerland has not only become, during these months of war, a highly industrial and efficient manufacturing country, but it has rendered splendid service as an enormous hospital for wounded prisoners who are either sent there to stay or pass through the country to be exchanged as invalids. These men number by the myriads, and naturally require very large transportation facilities.

Troop Transport Requirements

But there is another circumstance which adds to the demand for automobiles. While at peace, Switzerland is at present really on a war footing; many thousands of citizens are continually on border duty. This service includes a very large number of military posts on the alpine peaks on every side of the country, and as the men on duty are there only for short periods the transport of these troops, as well as the supply of food, necessitates the use of numerous motor vehicles.

Thus, in spite of the paralyzing of some industries, the whole population of Switzerland is kept busy, and the automobile is not the least factor responsible for this agreeable state of affairs.

Mention has been made of the difficulty of obtaining raw materials, because each belligerent supplies Switzerland with some materials, but insists that this must be used in no way advantageous to the enemy.

The Allies make the supply of cotton, rubber, etc., dependent on this condition.

The Central Powers take much the same stand with regard to the coal, steel, and oil they supply to the Swiss.

Vehicles of the Truck Type

Time and again the Federal Government has received notes on this subject from both sides; but it would seem—and this opinion has been voiced unofficially by a number of people who are in well-informed places and with whom the writer had interviews—that these notes are sent out by the belligerent governments with the chief intention toward home consumption, while every government in Europe is very glad that Switzerland is neutral and in all probability will remain so until the end of the war.

The machines, as already indicated, are principally built along truck lines, even where they are used for transportation of wounded or invalid prisoners, and where motor vehicles of this type are used they are, as a rule, built on the sightseeing style, which allows for a great number of passengers on one machine. However, there are also special bodies, such as large ambulance wagons, permitting the transport of eight, ten, or twelve men on stretchers. All these trucks are covered and equipped with doors or gatework.

Many Passenger Cars

In spite of the large number of trucks, however, there are a great many passenger vehicles proper being built and used. These machines vary in design and construction, depending on the purpose for which they are destined. Automobiles constructed for field work are as a rule constructed as lightly as is possible for the work they will have to do, and are distinguished by simplicity of design and ample ground clearance, seeing that they will have to do a great deal of work on very poor roadways.

It is a different matter with Swiss trucks. They are built along lines somewhat similar to those existing before the war and are heavy and solid in construction. The reason may be that Swiss engineers have not as yet been benefited by and drawn conclusions from the frontal experiences; but one of the reasons, no doubt, is that the powers purchasing these trucks realize the careful selection of material and labor used in constructing these trucks and order them with a view to specially hard work, such as transporting heavy ordnance, etc. Among the factories specially well adapted for such manufacture are a number of locomotive plants of international repute, although in their case it is not a matter of a factory having changed its complete character, for, of course, there is still a great market for railroad engines in all countries surrounding Switzerland. It would seem, however, that the making of automobiles, especially at the present, is more profitable, offering a fine incentive to all such plants which possess modern machine tool equipment.

Little Munitions Produced

One reason why automobile making has become such a big industry in Switzerland since the beginning of the war is the fact that the Swiss turn out very little munitions, properly speaking. Certain industries, such as watchmaking, which has lost a good deal of its export trade on account of the rise in transportation rates throughout the world, has taken up the making of munition accessories and parts, but none of these is assembled in Switzerland itself; they are sent to the countries of the Entente or Dual Alliance, as the case may be, where they are put together, or fitted together with products of the countries which purchase them. Therefore, the practice of fitting up any old blacksmith shop as a munition factory, as has been done in some countries, does not hold good in Switzerland.

Difficulty in Securing Materials

As mentioned above, there is always a certain difficulty about getting the materials for making automobiles, although this holds true of all kinds of materials, whether they are produced in Switzerland or imported from outside. Hence, the prices of automobiles are very much higher than before the war and seem to be continually on the rise; and, to make matters worse, the sources of materials imported by the Swiss for the purpose of manufacture and export are continually being restricted so as to raise the price of the articles sold to the enemy of the country which happens to sell to Switzerland. The prices of tires and of gasoline are in no way behind those of automobiles, and, if possible, rise more rapidly.

People Want Peace

These facts explain that, while every man in Switzerland is employed and making splendid money, compared with the ante-bellum days, there is not one in the republic who does not hope for the earliest possible close of the war. The Swiss seem to have their doubts as to whether their war-born prosperity will survive the war; but even so, they consider that the general expense of living among a crowd of fighting peoples is far in excess of the benefits. When you ask a Swiss business man for figures he shrugs his shoulders and tells you how many hundred per cent. the national debt per head has increased during the war, due to the need of preparedness all along the border.

Roads Greatly Improved

One of the blessings of the war is a general improvement of Swiss roads. There are now much more motorable roads than before the war. Not that Switzerland was poor in good roads before the war; but there were not enough in proportion to the attractions that country offers to motoring tourists. Furthermore, there were before the war a great number of roads shut to automobile traffic. The war has, in this respect as in so many others, been a great educator to the people in dispelling some old-fashioned prejudices; and in all likeli-

The FORVM

Horsepower Curves for Tractors

By B. W. Moses

THE necessity for an accurate and simple rating for tractors is a subject that is attracting considerable attention at present. When the term 20 hp. is used it may mean almost anything, one manufacturer takes it to mean the actual power at the draw bar, another to mean the number of horses the tractor will actually displace, another the brake horsepower of the motor, while another may even take the A. L. A. M. rating.

In the computation of power the two quantities that must be measured each time are the pull at the draw bar and the speed of the tractor (not of the engine). These two quantities can easily be obtained, the first by some kind of spring scale and the latter by the expedient of laying off distance stakes.

Knowing then that mechanical horsepower is the result obtained by dividing the product of pull in pounds and the distance traveled in feet per second by 550 it is very easy to obtain:

Hp. = 2.666 × pull in thousands of pounds × M.P.H.

And as an approximate rule it might be taken that the horsepower is equal to five times the pull in tons, times the speed in miles per hour.

In the accompanying diagram the draw bar pull in thousands of pounds is laid off horizontally and the mechanical horsepower is laid off vertically, while the radial lines are speed lines. To obtain the horsepower follow the line vertically that corresponds to the draw bar pull until it intersects the proper speed line, then the horsepower is on the horizontal line passing through that point. For example: What is the horsepower of a tractor pulling 5000 lb. and traveling at the rate of 3 m.p.h.? Answer: 40. Follow the lines *A*—*B*.

On the extreme left of the chart the equivalent horse pull is laid off. This horse pull is based on an animal that will exert a pull of 185 lb. while traveling at the rate of 2¼ m.p.h., and is equal to 1.08 mechanical horsepower. If for example it is desired to know what the equivalent horse pull for the above case is, simply extend the line *B* to the left, obtaining a little over 36 horses.

Another feature of the diagram is that of converting feet per hour to miles per hour or vice versa. On the extreme right the speed is laid off in thousands of feet per hour. And through the center of the diagram running vertically is a heavy line. This line might be called the speed line. The speed in feet per hour can be converted into miles per hour by simply finding the radial line passing through the point of intersection of the line expressing the thousands of feet per hour and the speed line. If in the above example the speed had been given as 15,840 ft. per hour instead of 3 m.p.h., the line *C* converts the distance into miles per hour and the problem is the same as before.

The diagram can be used for any power machine at any speed. If however the speed or the power is too great to be found on the diagram, it should be divided by some factor that will bring it down onto the chart and the result is to be multiplied back by the same factor, thus giving the correct power or speed required.

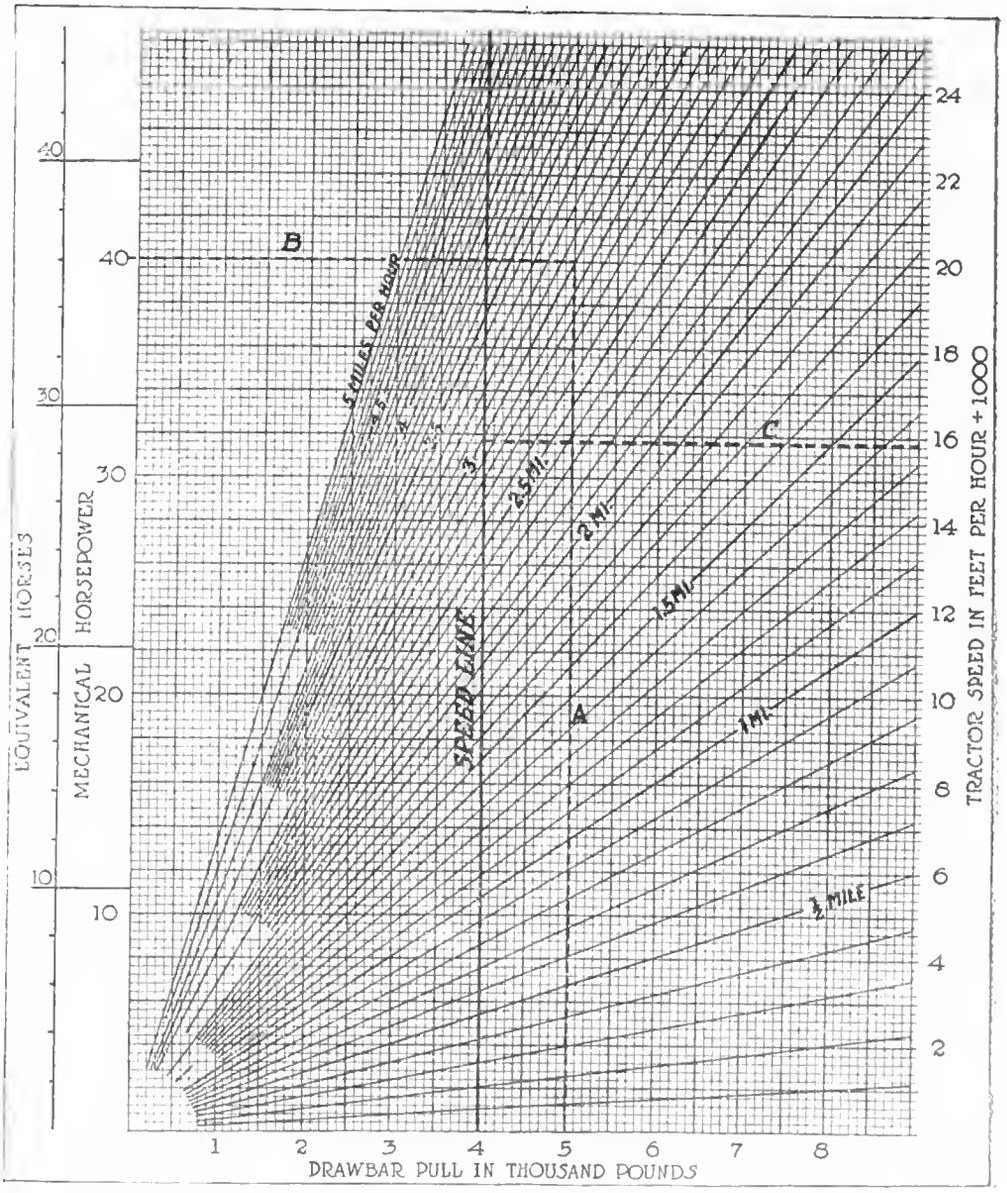

Diagram showing relation between horsepower and speed of motor tractors

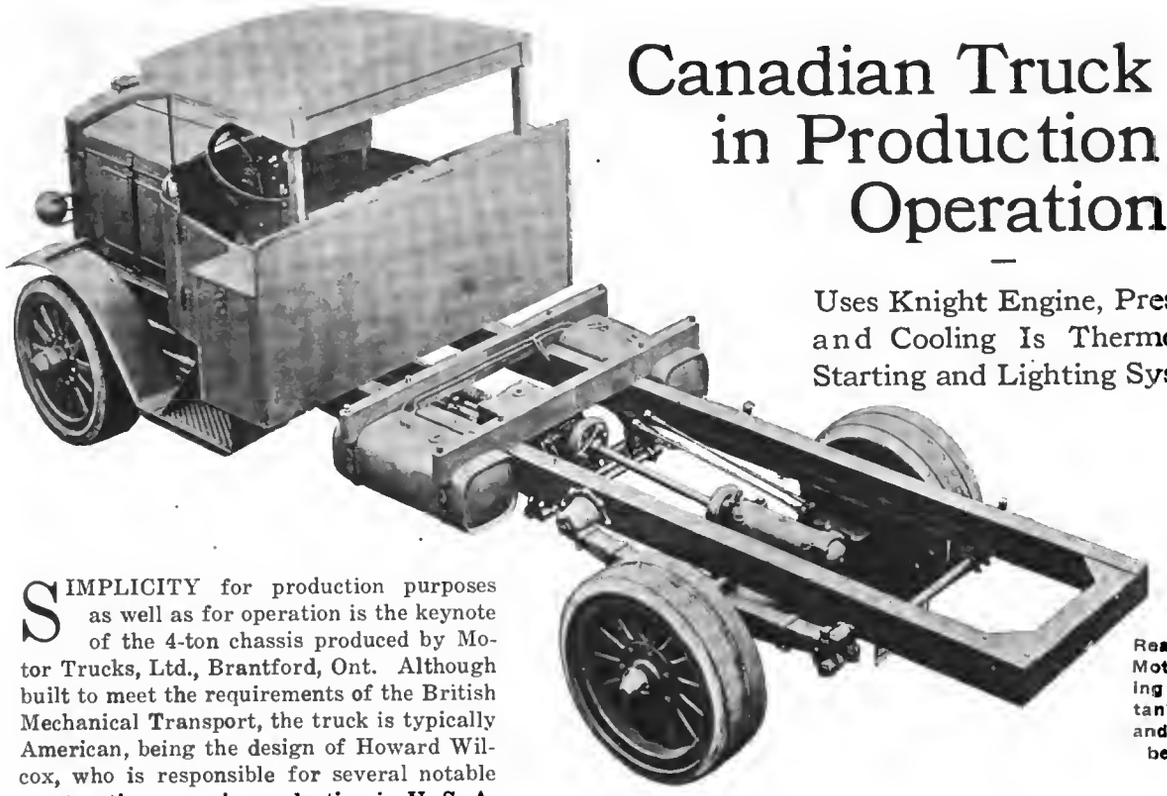
Canadian Truck Simple in Production and Operation

Uses Knight Engine, Pressure Oiling and Cooling Is Thermo-Syphon—Starting and Lighting System Fitted



Rear of chassis built by Motor Trucks, Ltd., showing the two 20-gal. fuel tanks, overhead worm and strong frame members. Note roomy cab

SIMPLICITY for production purposes as well as for operation is the keynote of the 4-ton chassis produced by Motor Trucks, Ltd., Brantford, Ont. Although built to meet the requirements of the British Mechanical Transport, the truck is typically American, being the design of Howard Wilcox, who is responsible for several notable constructions now in production in U. S. A.

A Knight four-cylinder 4 by 6-in. engine is a feature of the design, which is a worm-drive construction with a 159-in. wheelbase and a gear ratio in high of 8¾ to 1. Tires are 36 by 5, dual in the rear.

Fundamentally the chassis is simple. It is also silent and embodies a high degree of flexibility. In the frame—the very backbone of the truck—there is primarily simplicity, since there are no rigid cross-members save at the extreme rear end, where there is one large one to carry large gussets to maintain the rectangularity of the frame. It is cold pressed of ¼-in. stock, 7 in. deep, with 4-in. flanges.

This simplicity makes for ease and economy of assembly, it makes for accessibility to the parts and it makes repairs less difficult. By this simplicity the third characteristic of the design—flexibility—is secured, for with all of the cross-members, and only a few at that, of the tubular type, the frame becomes a true De Dion form, which, continuing the chain of cause and effect, permits the use of very flat springs.

These flat springs are accountable to a large measure, according to Mr. Wilcox, for the success of the Hotchkiss drive.

The greatest contribution to silence, as well as the most distinctive feature of the truck, is the Knight engine which is of the same type as adopted by the Fifth Avenue Coach Co. for its new buses, and built by the Moline Motor Car Co., Moline, Ill. It has four cylinders, 4 by 6, giving a formula rating of 25.6 hp., but having shown 65 hp. at 1800 r.p.m. on the block.

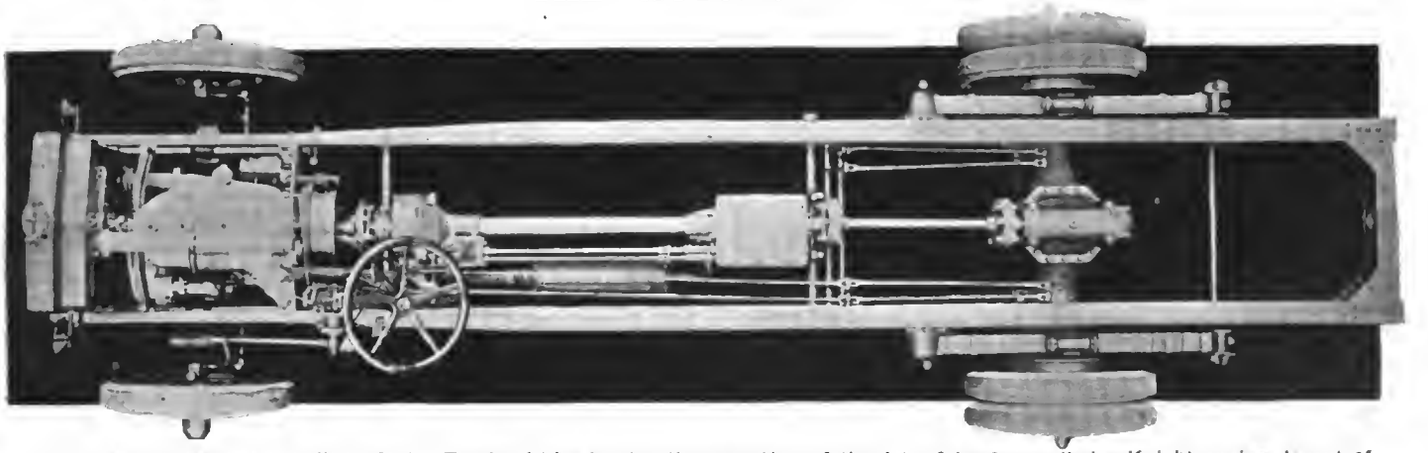
Cylinders are cast in block, together with the inlet manifold, which is completely water-jacketed. The sleeves are so placed in the cylinder that their upper ends are incased by waterjackets on both sides, and they are operated by eccentrics in the usual manner.

Pressure lubrication is secured from a gear-pump, forcing the oil through the drilled crankshaft to main and connecting-rod bearings at pressures up to 50 lb. per sq. in., which vary with the speed, thus providing automatic gradation of the oiling. There is no splash, but the spray from the cranks serves to lubricate the eccentric shaft and the wristpins. The wristpins are hollow and serve to convey the oil to the sleeves, which are oil-grooved and drilled and which in turn work the oil thoroughly between themselves and the cylinders.

Thermo-syphon water circulation is used and by dint of exceedingly liberal water spaces in the cylinder block as well as unusual radiator capacity, a somewhat sluggish circulation is made to have a cooling effect equal to a more rapid forced system through smaller passages. The radiator has unusual height, so that an excellent head of water is secured. Besides this, the top tank extends some distance above the top water header, so that an increased head is provided. The lower headers are two in number, one conducting the cool water to the front of and the other to the back of the cylinder block.

The radiator casing is entirely cast, comprising four pieces, the large top tank, a smaller bottom tank and two side plates.

A complete truck climbing a difficult grade. Note the high radiator and hood, the searchlight mounted on the dash and the substantial bumper bar



Plan view of the chassis built by Motor Trucks, Ltd., showing the mounting of the 4 by 6-in. four-cylinder Knight engine, layout of transmission system and overhead worm drive. Note mounting of electric units, amidship gearbox, etc. Springs are very flat, and this renders the use of Hotchkiss drive a logical feature

The cooling system has the unusual capacity of 17½ gal., most of which is in the radiator. The core of the radiator is of helically-finned copper tubes, individually demountable and sealed by cork gaskets without solder. The top and bottom plates are of copper or brass plate.

A high-tension single magneto with fixed spark cares for ignition automatically. The auxiliary electrical system consists of a Wagner starting and lighting outfit, with the generator and motor separate. The generator is driven from the same shaft which drives the magneto, this shaft being driven from within the timing gearcase by the same silent chain which drives the eccentric shaft gear from the camshaft. It also drives the V-belt for the 20-in. three-bladed cast aluminum propeller-type fan.

The starting motor, which drives the flywheel through teeth milled on it, was selected by testing for a motor powerful enough to start the Knight engine after being in cold storage at a temperature below zero for 24 hr.

The carbureter is a Zenith, which harmonizes very well with the rest of the chassis, since it has no adjustments, valves or springs. Incorporated with the carbureter is the Monarch gas-velocity governor, which operates without outside mechanical connections of any kind. The adjustment of this governor is easily made and is locked with a padlock, so that the driver cannot change it. In its setting, established precedent has been set aside, since it permits the motor a speed of 1800 r.p.m. It is said that the truck may safely be driven for a distance not to exceed 10 miles at 30 m.p.h., and for an indefinite time at 25 m.p.h.

The carbureter is fed by pressure from two tanks, mounted in an original manner. These tanks are 12 by 14 in., of bolster shape, each made of two seamless drawn steel shells, telescoped and welded. Each holds 20 gal., and they are suspended by steel straps from two yoke-like wood beams laid across the frame, so that the tanks lie just outside the frame side-members back of the cab. Pressure is automatically maintained by an air-cooled two-stroke air pump driven by the engine.

Gearbox Is Amidships

Unit power plant construction is not used, since on long wheelbases it is desirable to divide the shaft into two lengths to avoid whipping. This can be done with the best distribution of weight by placing the gearbox amidships. This also permits of greater accessibility and also allows the unit transmission embodied in this design to be employed. The engine is therefore independently mounted on three points, direct from the main frame.

Between it and the transmission unit is a fabric disk universal. The transmission unit comprises the clutch, gearbox, control unit, intermediate driveshaft and brake rocker-shafts assembled into a rigid unit, independent of the rest of the power and driving system. It is suspended on three spherical joints, one at the front, on a tubular cross-member and two at the rear, on the side members. At the front is the clutch housing.

The clutch is a Brown-Lipe dry-disk type, designed to run without oil and of such proportions as to be uninjurable through slipping. It connects with the Brown-Lipe gearbox by a long tube, inclosing the driveshaft.

The gearbox is square with a light removable cover on top. It affords four speeds and one reverse. The gears and shafts are nickel steel, heat-treated and the gears are of 5-7 pitch with 1¼-, 1½- and 1⅝-in. faces. An interlocking arrangement is provided to prevent engagement of more than one pair at a time.

A Rigid Assembly

Back of the gearbox is a tubular cross-member, rigidly attached to the back of the gearbox and, paralleling it are two brake rocker-shafts. Just back of the clutch at the front end is the selector or control unit for the gearset. The shifter-rods connect it with the gearset, and, due to the rigid assembly of the whole transmission unit, correct alignment is assured.

To a bracket at the side of the clutch the hand brake lever and the pedal are attached, their pull-rods to the brake rocker-shafts extending back in straight lines. The single pedal is mounted on the clutch throw-out shaft direct and carries a brake pull-rod besides, so that it fulfills the double duty of clutch release and foot brake.

Behind the gearbox the final or secondary drive is taken by a 26-in. solid shaft with two fabric-disk universals, to the worm-driven rear axle. This is essentially a Sheldon type, except that it has some special features of its own. One of these is the M & S worm self-locking differential. A number of trucks have also been built by this concern without any differentials. These axles have cast steel housings, side-by-side internal brakes and are of semi-floating construction.

The springs through which the torsion and propulsion are transmitted are of the banded type, steel bands being shrunk on at their middles in lieu of a center bolt, thus avoiding any weakening hole at this point. They are flat under load and have three reversed leaves on top to resist rebound. These rebound springs are equal to about one-fourth the thickness of the main springs. The front springs are 44 in. long and 3 in. wide and their eyes are bushed for ¾-in. diameter bolts. Rear springs are 56 in. long and 3½ in. wide, bushed for 1¼-in. bolts at their fronts and for 1-in. ones at the rear, or shackled end. Three rebound clips are used on each spring.

The axle clips are of the round type, bent in an arch over the springs without sharp bends, an iron filler block being inserted between them and the tops of the springs. The

Westinghouse Club of Practical Value

Technical Education of Employees Developed by Special Classes—Athletic Activities and Social Features Provide Ample Recreation

WELFARE work at the plant of the Westinghouse Electric & Mfg. Co., East Pittsburgh, Pa., has grown to a high state of efficiency in regard to educational, social and physical benefit to the employees. Organized in 1902, primarily for the educational benefit of the engineering apprentices, the Westinghouse Club has widened its scope so as to include membership not only from the above company, but also from the Westinghouse Air Brake Co., the Westinghouse Machine Co., Pittsburgh Meter Co. and the Union Switch and Signal Co. The membership now includes something like 850, mainly of the younger engineering students. Membership, however, is open to any factory employee, but owing to its having been organized primarily for the benefit of the technically trained students this class has so far predominated in the membership.

When the club was first organized its activities were mainly lectures on technical subjects, and the establishment of a reading room. Subsequently the club expanded and quarters were purchased where reading rooms, billiard and pool parlors and a completely equipped gymnasium were installed.

Membership in the club is recruited from all of the Westinghouse companies in the Pittsburgh district. The club offers an increasing scope of acquaintanceship among men other than those whom the average member meets in his business relations. It is interesting to note that the club membership during the current year includes men from over 160 different colleges and universities.

Committees Handle Activities

The activities of the club throughout the year are taken care of by specially appointed committees covering athletics, entertainment, technical sections, house, lecture, library, music, excursion and smoker.

The club also extends its operations beyond the factories in an endeavor to afford educational and instructive advantages. The work of the excursion committee is the best exemplification of this and is probably the most interesting work of the club to the new members. Excursions are made to the various manufacturing plants in Pittsburgh. These excursions cover a variety of different classes of manufacture and are conducted under the guidance of experts in the various lines. Provision is made for men on night turn to take these trips on Mondays.

Technical Work Important

One of the most important works of the club consists in the organization of regular classes for the systematic study of the theory, design, and application of the Westinghouse apparatus. Organized primarily as an educational institution, the club management has always felt that the opportunities for study and technical lectures and discussions could not be made too great. No other branch of the club work has been so popular, the enrollment in all the technical sections through the year totaling 951, some men taking work in two sections. The object of the sections is to supplement work in the factory classrooms and in the shops. The classroom work during the first part of the graduate students course takes up the construction and manufacture of apparatus, while shop work covers its actual manufacture. It is the intention of the club to have the members of the section prepare the papers or lectures and enter into the discussions and thus learn by actually performing the work. Beginning this year, a time allowance of 25 hr. per each half term toward completion of the apprenticeship course is made for each graduate student who does the work of a technical section to the satisfaction of the leader of the section.

Gymnasium Completely Equipped

For 2 years now, the club has had its present large gymnasium facilities and has thus been able to develop various athletic teams. The gymnasium room is 65 by 140 ft. and is equipped with the latest forms of athletic apparatus. The floor is also laid out for basketball, indoor baseball, three removable handball courts, and a banked running track with sixteen laps to the mile. Outdoor athletic activities are centered in baseball, tennis, and field sports.

The library has become an important part in the club life. Daily newspapers from all sections of the country are on file, so that every club member can keep in touch with the section from which he comes. A complete file of technical magazines is available. Sectional bookcases are added from time to time as the number of books secured increases. The reading room is visited, according to statistics, by more members than any other room in the house.

As a means of furthering acquaintance and good fellowship among its members, the entertainments held during the year are of great importance. This year in order that those in charge of entertainments could give more attention to the dances and special events a Smoker Committee was appointed to arrange for Apprenticeship Nights and Monthly Smokers.

The lectures have proved a feature of the club life due to the wide range of popular subjects. The idea of these lectures is to afford the members and their friends a means of keeping posted on the topics before the public, and to avoid technical subjects.

The technical man's ability along musical lines is demonstrated by the active interest taken in the various musical organizations fostered by the club.

Club Organization

The club is operated by a board of directors, three of whom are appointed by the company and three elected by the members, one each of three appointed by other companies and the president, vice-president and junior past-president who are elected by the members to these respective offices and thereby become ex-officio members of the board.

A paid manager and assistant manager are employed who devote their entire time to the club. It is the hope of the management that some time the company will have a building devoted to all of the welfare interests, including both the workmen in the shop and those in the offices. In the meantime the company is providing a number of different welfare methods, as told in previous paragraphs. One of the most active and beneficial is the Casino Technical Night School operated under the auspices of the company which affords instruction in the evenings for those employed by the company and others as well, at purely nominal rates. This is open to girls as well as boys. A banner attendance in this department has been made this year, something like over 850 students having matriculated.

Educational Activities of the Westinghouse Club

Below — Practical instruction supplements the work of the classroom in the technical educational courses of the Westinghouse Club. The illustration shows one of the sections at work in the machine shop where the students can see the working out of the theoretical matter which they have studied

Above—One of the technical sections at work in the drafting room, receiving instruction in the preparation of details of construction of apparatus produced in the Westinghouse plant

Above—The gymnasium is 65 by 140 ft., and is equipped with the latest forms of athletic apparatus for regular class and exhibition work. The floor is also laid out for basketball, indoor baseball, three removable handball courts, and a banked running track with 16 laps to the mile

The Automobile Industry in Switzerland

(*Continued from page* 938)

hood the automobile restrictions will be completely removed after the end of the war. There will be other progress in this respect, too, unless indications are misleading. Most likely there will be far-reaching license reciprocity with the neighboring countries, especially France and Germany, so that touring in Switzerland will be still easier, and foreign tourists will be attracted in numbers to make up for what the country has lost in this regard during the war. Already there is a good deal of discussion regarding more modern methods of coping with tourist business; plans are being made for construction of garages where before the war automobiles were kept out, and an intense automobile traffic is confidently looked forward to.

This analysis of the automobile situation shows to what an extent it has been necessary for the greater part of the population to find new occupations and for a great deal of manufacturing capital to turn to new fields of endeavor.

Turn to Car Building

To take up the last point, a number of factories whose entire or chief output consisted in embroidery and knitting machines have devoted practically all their attention to the manufacture of automobiles. In this course they have followed the example of one maker in Arbon, who during the past ten years had turned out quite a number of automobiles, especially commercial cars, which were highly successful, not only in Switzerland, but throughout Europe, and even outside the continent. At present this company makes automobiles only and has quite suspended the manufacture of textile machinery.

Smaller Manufacturers Interested

Such an example could not help stimulating kindred efforts on the part of smaller manufacturers, and this accounts for the great increase of automobile making in Switzerland. Needless to say that the call for automobiles, both in Switzerland and especially in belligerent countries, is so great that the automobile industry is very profitable, and that whoever is in possession of suitable machine tools endeavors to produce motor vehicles. There is, however, one important limitation to these endeavors, namely, the difficulty of obtaining raw materials.

Canadian Truck Simple in Design

(*Continued from page* 941)

shrunk-on bands are machined to accurate size to fit grooves in the spring perches, so that they transmit the propulsion instead of the clips.

Wheels are of wood, with square spokes, fourteen on the rear and twelve in front. The same sizes of tires are used front and rear, namely, 36 by 5, single in front and dual behind.

The steering gear, is on the left side. It is attached to the main frame side-member and has a steering column angle of 35 deg.

Great pains have been taken in the finish of this job. The hood is made of 16-gage steel in three sections. The top section is hinged to the dash and the side sections to the frame sills and detachable. The hold-downs are two in number, being forged and connected with the frame sills by springs to keep the hood tight and prevent rattling and at the same time allow for the movement of the radiator on its flexible mounting in response to frame weaving.

Fenders and steps are of 14-gage steel, pressed from one piece and held in place by heavy cast braces riveted to the tops of the fenders. A simple bracket of bent sheet steel supports the running board. The headlights are attached to forks extending horizontally on each side of the radiator.

The cab is constructed entirely of steel and has a seat wide enough for three large men. On each side of the seat is a large tool box and across the back is a wide bulkhead.

Some of the other ratios, speeds and dimensions are:

Gearset Ratios

First	4.84 to 1
Second	2.84 to 1
Third	1.50 to 1
Fourth	direct
Reverse	5.81 to 1

Total Gear Reductions

First	42.35 to 1
Second	24.85 to 1
Third	13.12 to 1
Fourth	8.75 to 1
Reverse	50.84 to 1

Truck Speeds in M.P.H.	R.P.M. 1,800	R.P.M. 1,000

Height to top of frame	32 in.
Overall width	7 ft.

Scripps-Booth Detachable Winter Top

THE detachable winter top illustrated at the right on the eight-cylinder Scripps-Booth is designed to appear as an integral part of the car, although it may easily be removed and the regular top mounted. The detachable top fits closely to the body of the car, with flush sides and will not rattle. Windows are removable and the interior is finished in gray whipcord with a dome light. Both the winter top and the regular top are furnished with the eight-cylinder model for $1,350, the price without the winter top being $1,175.

Detachable winter top mounted on the Scripps-Booth eight-cylinder chassis

ACCESSORIES

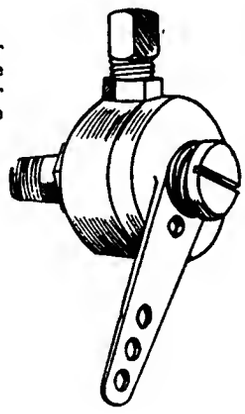
Primolite Headlight Lens

BY a prismatic construction this lens throws the greater part of the light upon the road straight ahead but diffused in such a manner that the driver can see cars coming from the opposite direction and also the road on both sides of the car, so that the danger of passing is eliminated. Light rays run to each side almost at right angles from the face of the lens, so that objects on both sides of the driver are distinguishable at a distance of 50 ft. back from the road. Each lens is divided into a series of vertical divisions, each of which is a convex lens, and as the face of the lens is frosted the convex divisions each throw the rays at diverging angles, these rays crossing and re-crossing those shining through the frosted portion, thus mellowing the light. For 8 to 9-in. headlights the lens sells for $2.90; for 9 to 9⅞ in., $3.50, and for 9⅞ in. up, $4.20.—Primolite Company, 945 Lemcke Annex, Indianapolis, Ind.

Primolite headlight lens which is designed to throw light upon the sides of the roads as well as straight ahead without glare

Hydrovaporizer

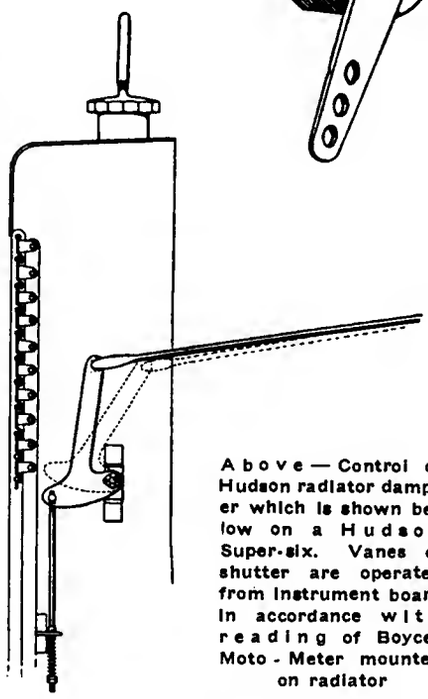
A mixture of water and air is injected into the intake manifold by this device. Water is drawn from the engine and air from the outside, mixed in the chamber of the device, and carried into the combustion chamber in a fine spray, it is claimed. The proportion of air and water may be controlled from the seat, and it is said that the efficiency of the engine is bettered and carbon prevented. Price, $6.—Accessory Mfg. & Sales Co., 1507 Hennepin Avenue, Minneapolis.



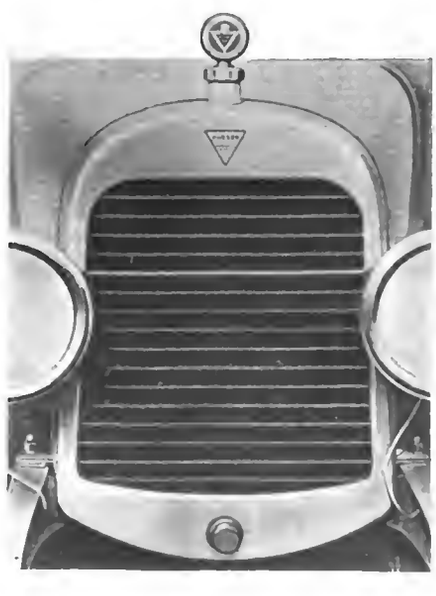
Hydrovaporizer for injecting a mixture of water and air into the intake manifold

Hudson Radiator Damper

By replacing the standard radiator shell of the Hudson Super-six with a special shell housing a shutter mechanism, as shown in the illustrations, the running temperature as indicated by a Boyce Moto-Meter may be controlled from a plunger on the instrument board, the operation consisting in throttling the air passing through the radiator. The vanes of the shutter may be left completely open, as in warm weather; completely shut, as in very cold weather, or at any point between these extremes which the Boyce Moto-Meter indicates as securing the best running temperature. In installing, it is only necessary to change the radiator shell, drill a hole in the instrument board and another in the dash, and then to connect the operating plunger on the instrument board with the bell crank of the shutter by a control rod. No machine work is required in the installation, which may be made in 2 to 3 hr. With the Boyce Moto-Meter, which is a necessary part of the device, the price is $25. If the car is already equipped with a Boyce Moto-Meter the remainder of the equipment sells for $15.—Hudson Motor Car Co., Detroit.



Above — Control of Hudson radiator damper which is shown below on a Hudson Super-six. Vanes of shutter are operated from instrument board in accordance with reading of Boyce-Moto-Meter mounted on radiator

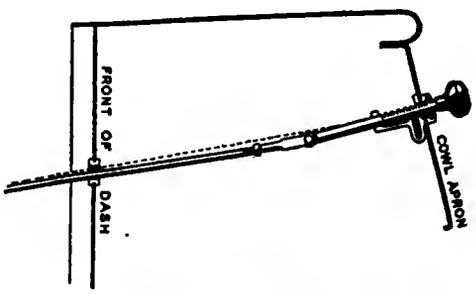


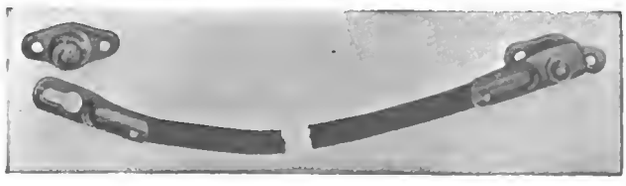
King Anti-Rattler

This anti-rattling device is made for attachment to the steering spindle of Ford, Overland and Dodge cars. A hanger is secured to each end of the tie-rod, the lower end rigidly supporting the spindle and carrying a spring that is said to automatically take up wear. It is easily attached by anybody. Price, $1.50 per pair.—King Specialty Mfg. Co., 207 Washington Street, Brookline, Mass.

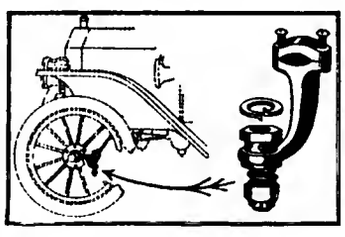
Ideal Robe Rail

The Ideal rail is detachable at one end to facilitate placing coats, robes, etc., in position. The center of the rail is leather over cord and the ends are nickel plated. It is regularly furnished in 18½-in.



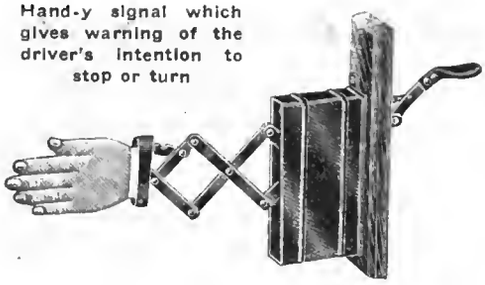


Ideal robe rail which is detachable at one end



King spindle joint anti-rattler

Hand-y signal which gives warning of the driver's intention to stop or turn



lengths although other lengths are made to order. There is a special rail 24 in. long for Ford cars. The rails sell for 75 cents.—Ideal Brass Works, Tenth Street and Canal, Indianapolis.

Hand-y Signal

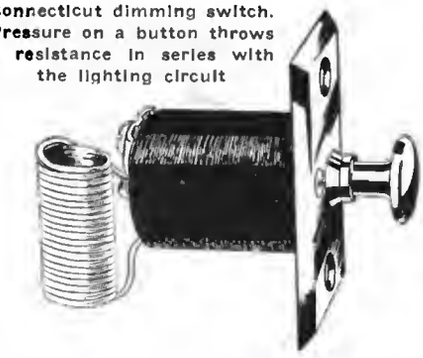
Extending a hand from the side of the car on a lazy tongs device operated by the driver, this device gives warning of an intended stop or turn. The signal consists of a bright-red metal hand fastened to the end of steel folding members that fold into a metal case attached to the side of the car. The hand is swung to the extended or closed position by a lever on the open-car model; on the closed-car model it is operated by a chain. It may be attached to any car in 5 min., it is said. Special emphasis is laid on the simplicity of its installation on closed bodies. For open cars the signal costs $3; for closed cars, $3.50.—Kaenjay Sales Co., 105 Chambers Street, New York.

Nitrojector Spotlight

This searchlight has an adjustable focus mounted on the windshield by means of a swiveled clamp. The rays of the light are controlled by a shutter around the bulb of the lamp and controlled by a thumbscrew placed in the handle of the lamp. The rays may be controlled from a small ribbon having a diameter of 4 ft. at 500 ft. to the general illumination common to all lights, it is claimed. Another advantage claimed is that the lamp is entirely free from glare. Price, $10, complete.—Hawthorne Mfg. Co., Bridgeport, Conn.

La French Spark Plug

These plugs are claimed to enable the car owner to get the same mileage under similar conditions of load, road and distance with a mixture of 60 per cent kerosene and 40 per cent gasoline in the tank as with gasoline only. A feature of the construction is the use of porcelain baked inside the independent steel shell. The porcelain is also protected above the shell by Bakelite. An asbestos packing around the independent steel shell provides for heat expansion and a twin conical porcelain prevents short-circuiting. The construction of the plug is clearly shown in the accompanying illustration. The manufacturer claims that it is never necessary to take this plug apart to clean it,



Connecticut dimming switch. Pressure on a button throws a resistance in series with the lighting circuit

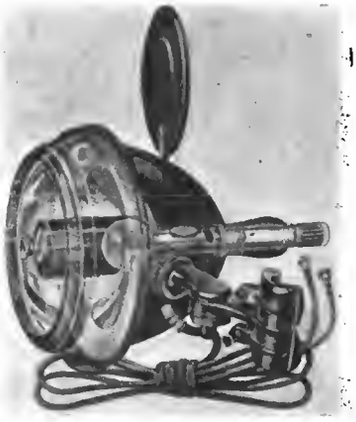
and the spark gap, which is ⅛ in. wide, is unusually accessible besides having the advantage of extending well down into the combustion chamber. Plugs are made in ½ in. and ⅞ in. S. A. E. sizes and sell for $1.—La French Spark Plug Co., 206 Meredith Street, Dayton, Ohio.

National Safety Signal

The driver's intentions are manifested by electrically lighted semaphores attached at each side of the windshield. The light carried at the end of the left arm is red, the one at the right green, and either or both may be swung from the vertical to the horizontal position by means of a knob attached to the dash at a point convenient to the driver. As the light drops to the horizontal position it lights automatically, pointing the direction that the driver intends to turn. Price, $15, installed.—National Auto Signal Co., 251 West Seventh Street, St. Paul, Minn.

Connecticut Dimming Switch

A button switch located at a point convenient to the driver throws a resistance in series with the lighting circuit, causing the lights to grow dim. The resistance consists of a small coil of special wire connected at each end to two binding posts secured in the end of a hollow fiber cylinder. On the interior of this cylinder are two brass brushes, secured at one end to the binding posts, the other ends resting on the switch plunger. The inner end of this plunger



Nitrojector spotlight

is uninsulated and grooved, the balance of the plunger being insulated so that when the plunger is pressed in as far as possible the ends of the two fiber brushes are disconnected and the current forced to pass through the resistance wire. By pulling on the plunger the two brushes come into contact with the metal end, are short-circuited, and the lighting current allowed to pass unrestricted. The installation requires only that a ⅞-in. hole be drilled in the dash, the insulating cylinder slipped in place and the plunger plate screwed onto the face of the dash. One wire of the lighting circuit is then cut at any point and each of the two ends attached to its respective binding post on the dimming switch.—Connecticut Telephone & Electric Co., Meriden, Conn.

Steering Gear for Fords

A steering gear installation for Fords. The operating member is a hollow sphere, having a spiral groove cut in its surface. A boss on the yoked shaft bearing the steering arm rides in this groove, and is moved or held by the metal sphere. The gear works on roller bearings, and is said to be exceptionally easy to operate. It is also claimed to be exceptionally easy to operate, and to require but one turn of the wheel to throw the wheels from one extreme to the other.—Price, $12.50.—Nash Mfg. Co., 1723 O Street, Lincoln, Neb.

Industrial Miscellany

Factory

Dupont Fabrikoid Co., Toronto, Ont., is erecting new buildings. Estimated cost of buildings is $75,000 and estimated cost of machinery $175,000.

Crown Tire & Rubber Co., Ralston, Neb., is planning a factory to consist of six buildings.

Field Motor Co., Grand Rapids, Mich., has purchased the Brown & Sehler factory in this city for $14,000 and will manufacture a motor under patents owned by E. A. Field.

Auto Specialties Mfg. Co., Joliet, Ill., will build a two-story, 80 by 400 ft., factory on Edgewater Field at a cost of $25,000.

Canton Auto Parts Mfg. Co., Canton, Ohio, recently incorporated with a capital of $300,000, is planning a 50 by 200 ft. plant.

Mayo-Skinner Mfg. Co., Chicago, is now in its new home at 2115 Elston Avenue, Chicago. This company manufactures hand pumps, spark plug pumps, air compressors, electric garage pumps.

Doehler Die-Casting Co., Brooklyn, N. Y., has let a contract for the construction of a steel and concrete addition, 50 by 100, seven stories, and costing about $150,000.

C. A. S. Products Co., Columbus, Ohio, manufacturer of automobile gears, has completed alterations at its plant, which has more than doubled in capacity. The company is employing 130 men.

Sheller Wood Rim Manufacturing Co., Portland, Ind., which is capitalized at $25,000, has been formed. The company will manufacture single-piece wooden automobile steering wheel rims, the patents on which are held by H. E. Sheller. Directors of the company are Mr. Sheller, E. J. Minch, A. F. Blowers, E. M. Haynes and Carl Bimel. Plans are under way for the erection of a new plant for the company.

H. and M. Auto Parts Co., Cambridge City, Ind., has been incorporated with a capitalization of $10,000 to manufacture piston rings and piston heads. The officers are O. E. Huddleston, president; C. J. Marson, vice-president, and C. J. Marson, secretary-treasurer. The company has set no date for beginning operations.

Mitchell Motors Co., Racine, Wis., is building several thousand feet of new sidetracks and loading platforms, the existing system of more than three miles of trackage in and around the plant being inadequate to handle the record-breaking shipments of Mitchell cars. Both the Chicago & Northwestern and Chicago, Milwaukee & St. Paul lines run directly into the big works and provide unusually good facilities for shipping.

Personal

A. J. Miller, president; J. H. Wells, vice-president, and E. P. Humphreys, secretary-treasurer, are the officers of the recently formed Bellefontaine Automobile Co., Bellefontaine, Ohio, to manufacture automobiles.

D. J. Hayden, formerly sales manager of the Marion Motor Car Co., Indianapolis, Ind., is the head of a new company, the Hayden-Steele Co., which will handle the retail sales of Hupmobiles in Indianapolis and Marion County. The new firm has headquarters at 544-546 North Meridian Street. Associated with Mr. Hayden is J. P. R. Steele, secretary of the firm, who for several years has been Southern manager for the D. L. Auld Co., Columbus, jewelry maker.

E. E. Russell has been appointed general purchasing agent of the J. I. Case Threshing Machine Co., Racine, Wis. His appointment takes effect Jan. 1. Mr. Russell has been with the Case Company since 1889. For the past 12 years he has been in charge of foreign sales. Prior to that he had served the company as salesman, collector, branch house manager and assistant sales manager; later was engaged in opening up a number of foreign branches, which led up to the position of manager of foreign sales. He has also been connected with the cost department.

Capt. Oliver Hezzelwood has resigned his position as manager of the Toronto branch of the McLaughlin Motor Car Co., in order to devote all his time to military work. Captain Hezzelwood was president of the Citizens' Recruiting League and is now acting as a special recruiting officer in the Toronto military district. C. M. Ricketts succeeds Mr. Hezzlewood.

Personal

S. R. Scott has become district sales representative of the Denneen Motor Co., Cleveland, maker of the Denmo trucks. This company has appointed the Butler-Veitch Co., Berkeley, Cal., as its distributor in that territory.

George Price will handle the sales department of the J. A. & W. Bird Co., Boston, covering the entire territory south of New York, as far west as the Mississippi, and also including the states of Louisiana and Texas. He was formerly manager of its New York office.

C. T. Kenworthy has become vice-president and general manager of the Roamer Motor Car Co., Chicago. He was formerly distributer for the Rauch & Lang electric in New York.

T. E. Hanika, an Indianapolis newspaper man, has been appointed manager of the advertising department of the Gibson Co., Indianapolis, Ind., Overland and Willys-Knight distributor in Indiana, and automobile tire and accessory dealers. He succeeds R. T. Farrington, who has gone to San Francisco, Cal., to engage in publicity work.

James Coggeshall has been appointed manager of the wholesale department of the R. E. Taylor Co., New York, distributor for aGrford trucks in this city, New Jersey and New England.

W. P. Pollitzer has become sales manager of the Rock Island Mfg. Co., Rock Island, Ill. He was formerly Chicago branch manager of Edw. V. Hartford, Inc., Jersey City, N. J. The local company manufactures hardware specialties and automobile specialties. Mr. Pollitzer was with the Hartford company for 15 years. He takes up his new duties Dec. 1. Edward Leinbach will succeed Mr. Pollitzer at Chicago.

R. Adamson has been appointed manager of the Birmingham, Ala., branch of the Ford Motor Co. R. C. Ruggles, former chief clerk, has been made assistant manager. G. C. Nicholes, who came to Birmingham from Seattle, has been transferred to Cincinnati as manager of the assembling branch in that city.

A. E. Morrison has joined the staff of the Maxwell Motor Co., Detroit, as special sales representative. Mr. Morrison was formerly branch manager on the Pacific Coast for the Hupp Motor Car Corp.

Dealers

Nova Scotia Velie Co., New Glasgow, N. S., has been formed to handle the Velie car.

Southern Arizona Motor Co., Tucson, Ariz., has been made distributer for the Mitchell.

S. H. Blackburn and Edward Olson have been appointed Arizona agents for the Pullman, with headquarters at 235 West Washington Street, Phoenix.

G. S. Holvey, who has been operating as the Holvey Motor Truck Sales Co. in Rochester, N. Y., will, on Dec. 1, become city sales manager of the Selden Motor Truck Sales Co., Rochester. A local branch will be established in Rochester.

J. B. Crockett Co. has secured the exclusive sales rights for the Branford carburetor in South America, Australia, New Zealand, Tasmania, South Africa, Straits Settlements and Dutch and British India. The Branford carburetor, marketed by the Holt-Welles Co., 1790 Broadway, New York, is designed for Fords and other cars.

Boice Motor Equipment Co., Boston, is now handling the Heinze-Springfield starter for Fords, the Vesta Accumulator Co.'s products. It also represents the K. W. Ignition Co. and the Standard Thermometer Co.

Automobile Supply Co., Tacoma, Wash., has been appointed distributer for Rayfield carburetors for all of western Washington, Kittitas and Yakima counties in eastern Washington.

W. H. Wallingford, Portland, Ore., Ford agent, has moved into larger quarters at 908 Alder Street.

J. E. Tryzelaar, Portland, Ore., has been named distributer for Grus Spring Oiler and opened headquarters at 29 N. Broadway.

Richard Rinne, Tacoma, Wash., has purchased the Commercial Auto Co. He has also taken over the agency for the Velie.

E. M. Lang, Auburn, Wash., has secured the territory in Auburn and adjacent territory for the Maxwell, Oakland and Chalmers.

Kaenjay Sales Co., 105 Chambers Street, New York, which has taken over the exclusive distribution of the Hand-y signal, is composed of L. T. Kauffmann and R. L. Jones, both of whom have had previous connection with the industry. Mr. Kauffmann was sales manager and Mr. Jones factory superintendent of the Nonpareil Horn Mfg. Co., New York.

Van Cortlandt Vehicle Co., New York, has opened salesrooms at Sixty-third Street and Broadway to handle the Peerless cars, formerly handled by C. T. Silver. Walter Woods is manager and J. A. Clark sales manager.

Marathon Tire & Rubber Co., Ltd., St. Catherines, Ont., has appointed the following distributers: Wood Vallance & Leggatt, Ltd., Vancouver, and Wood Vallance, Ltd., Winnipeg and Calgary, distributers for Manitoba, Alberta and Saskatchewan.

Constant Pressure Cycle Truly Efficient

(*Continued from page* 936)

than constant volume engines, is entirely justified, our critic to the contrary notwithstanding.

Utilization of exhaust heat brings to the proposed cycle another advantage. It enables the use of heavy fuel which without this heat would be difficult to vaporize. At practical temperatures already actually obtained, it has proved possible to make a fixed gas of the heaviest oil and to thoroughly mix it with the proper proportion of air prior to combustion. On this account, if for no other reason, the proposed engine bids fair to fill a long felt want for a prime mover free from the inherent difficulties of the Diesel engine while not dependent on highly volatile fuels for satisfactory operation.

Concerning the question of flexibility it should be noted that it is possible to vary the point of cut-off exactly as in the case of a steam engine. When the point of earliest feasible cut-off is reached, a further modification of the card may be obtained by throttling. Thus both dimensions of the card may be varied by a simple control device, with corresponding accommodation to load. In other words the proposed engine must be exceptionally flexible.

We shall not here attempt a comparison of the constant pressure and constant volume cycles with expansion carried to atmosphere for the reason that no practical constant volume engine utilizing means for expanding to atmosphere has yet been recognized. We have however already shown the utter fallacy of Mr. Napier's deduction as to relative cylinder volumes by proving that the constant pressure engine will develop more power per unit of cylinder volume at full load than the constant volume engine is able to do.

We readily admit that at light loads (where expansion is carried to atmosphere) the constant pressure engine's cylinder volume is relatively great as compared to the work output. But (even though expansion to atmosphere is not practicable in constant volume engines) it is equally true that at light load constant volume engines also have a very large cylinder volume as compared to their power output.

In view of the foregoing it would appear that our critic had jumped to the conclusion that, whereas the old Brayton type of constant pressure engine had proven an unsuccessful competitor to the Otto type, all constant pressure engines suffer the same or similar limitations. In point of fact the proposed constant pressure engine eliminates the shortcomings of the Brayton type while still retaining the latter's numerous inherent advantages. It thus introduces a new type which bids fair to replace in time engines of the Otto, Diesel and semi-Diesel types.

Mr. Napier closes his criticism with the statement: "The burner described and illustrated in considerable detail will not, however, work as an igniting device for a reciprocating engine." We make no claim to this effect. In fact a spark plug with coil or magneto is expected to answer this purpose —as is the case with the constant volume engines. Concerning the functioning of the burner for the purpose intended, the opinion of Mr. Napier is valueless since experiments already concluded have established the practicability of the burner.

Stewart Products

Winter Business Leaders

Stewart Products are the leaders all the year 'round. They are 365-day-in-the-year sellers—sold 52 weeks running—straight through 12 months.

Stewart Products know no seasons—motorists *need* and *buy* them in winter and summer.

For example, there is the Stewart-Warning Signal—an absolute necessity for winter driving. In winter motorists are driving, all muffled up in heavy clothing, side curtains up, or with a winter top. Oftentimes the vision is obscured by snow and sleet. Then, the efficient, far-sounding Stewart Warning Signal is the only safe-guard.

Dealers can sell every motorist a Stewart Warning Signal by merely pointing out how necessary it is.

And the other Stewart Products—the Speedometer, Vacuum System, Tire Pump, Spark Plug—are all just as necessary in winter.

Live dealers will do a *big* Winter Business with Stewart Products.

Any State May Tax Non-Residents

N. J. Motor Laws Upheld by U. S. Supreme Court in Case Against F. J. Kane

Washington, D. C., Dec. 4—The United States Supreme Court in a decision to-day established the right of any State to tax non-resident automobile owners for the use of their roads. The decision is of national import in that it lays the way open to changes in the laws of those States which should decide to take advantage of to-day's ruling.

According to the decision, a State may impose a tax on the use of non-resident automobiles, rather than upon the machines themselves, to compensate for the wear and tear on highways.

The decision was the result of the arrest of F. J. Kane of New York for operating an automobile in New Jersey without registering his car there. The case was based on the violation of three provisions of the New Jersey law; first that Kane had failed to register his car in New Jersey; second, that he failed to pay the tax imposed on non-residents; and third, that he failed to file with the Secretary of State a power of attorney. The last provision was to enable residents who had suffered injury at the hands of non-resident motorists, to prosecute their claims for redress in that State instead of being compelled to follow the non-resident to his home State, wherever that might be.

Both New Jersey and Maryland impose a graduated license tax, on both residents and non-residents, based upon horsepower. In January, 1915, the Supreme Court upheld the Maryland statute as not burdensome on interstate commerce, but in the New Jersey case the contention was made that the taxes were not solely for adminstration costs of regulation and registration of automobile traffic, as was the case in Maryland.

The law in question is that of 1906, as amended in 1908 and known as the Freylinghuysen law, which has been since considerably modified. Though New Jersey has, since the litigation started, adopted reciprocal legislation as to visiting motorists, the decision, really a test case, may change the laws of the States, even going so far as to nullify all reciprocal relations between the various States.

Charles Thaddeus Terry, well known New York lawyer, who has been an able exponent of rational automobile legislation in the East, claims that this decision, relating to non-resident registration only, does not affect the greater argument as to whether a resident motorist should be required to pay a tax greater than the bare cost of registration. This question has yet to be settled.

—

Collins Is Chevrolet Sales Manager

New York., Dec. 1—J. S. Collins has become sales manager of the Chevrolet Motor Co. of Michigan, with headquarters at the Flint factory. Mr. Collins succeeds F. K. Lane, resigned, and will have charge of the territory embracing the states of Michigan, Indiana and Ohio and portions of Wisconsin, Illinois, Kentucky, West Virginia, Pennsylvania and New York.

He spent 13 years with the International Harvester Co., passing through several promotions and reaching the post of assistant general agent at Jackson.

—

Promotions at Chalmers

Detroit, Dec. 4—E. C. Morse, vice-president in charge of the sales for the Chalmers Motor Corp., has been appointed general manager of the company. W. P. Kiser, treasurer, has been promoted to secretary and assistant general manager. D. T. Turnbull succeeds Mr. Kiser as treasurer.

White Four Has 16 Valves

Plain-Bearing Crankshaft, Unit Power Plant and Center Brake Lever Features

Cleveland, Dec. 4.—Summing up engine performance as a matter of valve efficiency, the engineering department of the White Motor Co., Cleveland, has evolved and is just about to start production on a sixteen-valve four. Accompanying the new model there are a number of other innovations on the chassis which are notable departures from previous White practice.

This is the first White unit power plant, and it incorporates a plain bearing crankshaft instead of the ball-bearing design which is continued on the other models. The cylinders have removable heads, the oil is carried in the lower part of the aluminum crankcase instead of in a dash reservoir, and the entire appearance of the unit does not resemble previous products in any way.

Many Refinements

All through the chassis are a number of alterations which mark advancement in design. There is a cane type of gearshift lever, with a standard gate instead of the cross-over shifting arrangement formerly employed. The brake lever is in the center instead of at the left side, allowing a clear passageway through the left front door. The springs are semi-elliptic and the spare tires, instead of being carried in a well on the running board, are now supported on a bracket at the rear. In fact, a score or more of altered details can be located at a glance.

Most of the interest in the new car is focussed on the power plant. Here the lessons learned on the race track

(*Continued on page* 978)

Five Car Companies Raise Prices

Winton, Mitchell, Saxon, Allen and Premier Announce Revised Lists

CLEVELAND, Dec. 4.—The Winton Co. will increase the price of all its models by $200. The raise becomes effective Dec. 15.

Mitchell Increases Prices $100

RACINE, WIS., Dec. 1—The Mitchell Motors Co., this city, increased to-day the price of the Mitchell and the Mitchell Junior $100.

Saxon Six Price Now $865

DETROIT, Dec. 5—The price of the Saxon six has been increased from $815 to $865, due to the increased cost of labor and materials. The raise takes effect Jan. 1.

Premier Raises Car Prices

INDIANAPOLIS, IND., Dec. 1—The Premier Motor Corp., this city, has raised its prices on the seven-passenger touring car and four-passenger roadster from $1,685 to $1,895, on the limousine and town car from $2,950 to $3,150, and on the sedan from $2,685 to $2,900.

Allen Raises Closed-Car Prices

FOSTORIA, OHIO, Dec. 5—The Allen Motor Co. will increase the price of its coupé and sedan $100, effective Jan. 1. The new price for the coupé is $1,175 and for the sedan $1,195.

Perry Again in America

DETROIT, Dec. 2—P. L. D. Perry, president of the Ford Automobile Co. of Great Britain, is again in this country, following a recent trip to England. Mr. Perry states that the British government has issued orders to automobile makers which prohibit them from manufacturing cars for private persons except under special license.

De Lorenzi Sails for England

JACKSON, MICH., Dec. 1—E. A. De Lorenzi, service engineer of the Briscoe Motor Corp., has sailed for England to enter the transportation department of the Allies.

Chase Joins S. A. E. Office Staff

NEW YORK, Dec. 5—Herbert Chase has joined the office staff of the Society of Automobile Engineers. He was formerly connected with the Automobile Club of America as laboratory engineer and chief engineer. His new capacity will be that of assistant secretary. He is at present treasurer of the society and a member of its council, and has taken a prominent part in the activities and conduct of the Metropolitan Section.

His preparatory engineering education was had at the Pratt Institute. He was graduated as a mechanical engineer at Sibley College, Cornell University, in 1908.

Duryea Forms $4,000,000 Company to Build $250 Car

WILKES-BARRE, PA., Dec. 5—The Duryea Motors, Inc., of which Charles E. Duryea is president, has been formed with a capital of $4,000,000 to build the Duryea Gem at $250. This car will seat three persons. Other features include the Duryea patented roller drive.

Negotiations have been closed for a factory site and the Cutlery Works plant in the southern part of the city has been leased to start manufacturing.

Plans are to open the factory in the immediate future, just as soon as 20,000 shares of the stock, par value $5, is bought by the people of this city.

Dennet Resigns from Packard

DETROIT, Dec. 1—M. S. Dennet, chief inspector of the Packard Motor Car Co., has resigned. Mr. Dennet will represent the Muskegon Motor Specialties Co. and the Ajax Forge Co. in Detroit.

Reo Earnings Total $4,031,070

Assets of Car and Truck Cost $11,978,307.98—Surplus $3,849,828.20

LANSING, MICH., Dec. 1—The net earnings of the Reo Motor Car Co. and the Reo Motor Truck Co. for the year ending Aug. 31, 1916, were $4,031,070.26. Current assets were reported as amounting to $7,610,501, with a surplus of $3,849,828.20. Total assets are $11,978,307.98, capital assets amount to $4,277,674.06, and current liabilities are $1,191,229.78. This strong financial position is stated in a balance sheet at the close of business, Aug. 31, 1916.

The current assets show an increase of $2,776,845.36, as compared with the current assets of $4,833,655.75 on Aug. 31, 1915. Other important items mentioned in the report are certificates of deposit of $320,000, cash on hand in banks $1,360,517.97 and inventories of finished product, supplies and materials on hand amounting to $4,904,511.23.

It is thought, among some of the stockholders, that the company's annual meeting on Dec. 19 will witness a large stock dividend distribution, because of the large residue of unissued stock and surplus. The balance sheet follows:

ASSETS

Current assets			$7,610,501.11
Cash on hand and in banks		$1,360,517.97	
Certificates of deposit		320,000.00

Overland Men Take 25,925 Cars

2237 Dealers and Guests at Convention Inspect 1917 Models and Plant

TOLEDO, Dec. 6—Willys-Overland dealers closed contracts for 25,925 cars, aggregating more than $20,000,000 in value, during the first 2 days of their annual convention at the factory of the Willys-Overland Co., this city. The new Country Club model proved most popular with the thirty-eight distributors from seventeen States. Dealers and guests numbering 1027 arrived to-day from all parts of the country, bringing the total attendance to date up to 2237.

Anderson and Young Promoted

DETROIT, Dec. 6—Lee Anderson has been appointed vice-president of the commercial division of the Hupp Motor Car Corp., this city, Dubois Young has been appointed vice-president of the manufacturing division of the company. Mr. Anderson, who has been with the company for 2 years, was formerly advertising and commercial manager.

N. A. C. C. Export Conference in January —Nov. Shipments 17,250 Carloads

NEW YORK, Dec. 6—Directors of the National Automobile Chamber of Commerce at their meeting to-day voted to hold a meeting in January of the export managers of the companies holding membership in the organization. Exports have been increasing every year and the figures for 1916 will exceed $160,000,000.

Notwithstanding the shortage in freight cars, which has seriously affected the industry, shipments of automobiles for November were 17,250 carloads as against 17,138 for the same month last year. Report was made at the investigation of the Interstate Commerce Commission regarding the rules and practices of railroads taking interchange of cars, and it was clearly shown that this service has been seriously impaired by the cars being arbitrarily used in other services. It was also reported that a committee of presidents of the American Railway Assn. had agreed to establish at Washington a conference committee on car efficiency, consisting of five operating officials to co-operate with the Interstate Commerce Commission in an effort to relieve the freight car shortage.

It is expected that the railroads will soon advance their per diem charge for the use of freight cars by other roads from 45 cents to $1.00 or $1.25 per day.

Charles Clifton, president of the N. A. C. C., gave his annual complimentary dinner to the directors at the Hotel Biltmore last night.

Tener Maxwell Sales Director

DETROIT, Dec. 5—T. J. Tener has become director of sales of the Maxwell Motor Co. He was formerly Pacific Coast zone manager. C. E. Zebbins, formerly sales manager, is now assistant director of sales. Charles Gould, formerly service manager, is now sales manager. G. S. Gamble has been appointed assistant sales manager.

Herschell-Spillman Capital Tripled

NORTH TONAWANDA, N. Y., Dec. 1—The Herschell-Spillman Co., this city, will increase its capital stock on Jan. 1, 1917, from $250,000 to $750,000.

This increase in stock is made necessary in order to provide facilities to take care of the company's increase in business during the past year.

France Heavy Buyer in October

Leads European Countries in Purchase of Cars—United Kingdom Heads List

WASHINGTON, D. C., Dec. 2—Among European countries France was the heaviest buyer of American automobiles in October last, according to export figures compiled by the Department of Commerce. Five hundred and twenty-two cars, valued at $1,782,088, were shipped there during that month. During the corresponding month of last year France imported 298 cars, valued at $912,139, from this country. During the 10 months ended October the shipments of cars to France increased from 5183, valued at $13,038,767, in 1915, to a total of 7019 cars, valued at $18,311,-143, in 1916.

United Kingdom Purchases Decline

Exports of cars to the United Kingdom amounted to 684 machines, valued at $1,687,152, in October last, as against 2021 cars, valued at $2,730,468, in October a year ago. There was a big falling off in the exports during the 10 months' period, the shipments declining from 21,455 cars, valued at $31,379,217, in 1915, to 7959 cars, valued at $13,763,-990 in 1916, a result of war conditions and rulings.

Russia's Gain

Russia did not figure in the export returns last year, but during October last that country imported 116 cars, valued at $287,590, while during the 10 months of this year the imports amounted to 2968 cars, valued at $8,199,-

$10,000,000 in Cars Held Up

Makers May Suspend Manufacturing if Relief Is Not Forthcoming

DETROIT, Dec. 2—More than $10,000,000 worth of automobiles are held up awaiting freight cars for shipment. Many automobile makers will be forced to suspend manufacture if relief is not immediately forthcoming. These were statements made yesterday at a meeting of the traffic committee of the National Automobile Chamber of Commerce held in Detroit.

The committee named two committees who will visit railroad officials throughout the Central Freight Association territory and in the East to urge compliance with the Interstate Commerce Commission's recommendation that automobile cars be returned promptly to their home lines.

Traffic men named on the committees include H. R. Moule of the Chalmers Motor Car Co., A. C. Westfall of the Cadillac Motor Car Co., C. W. Eggers of the Willys-Overland Co., J. R. Graham of the Reo Motor Car Co., H. M. Newlin of the Maxwell Motor Co. Mr. Eggers is chairman of the traffic committee.

"There are approximately 30,000 automobile freight cars in the Central Freight Association territory and on Eastern trunk lines that are being used for all kinds of shipments other than automobiles," stated Mr. Eggers, following yesterday's meeting, "and we shall try to obtain the return of these cars. We shall point out to the railroad officials the recommendation made by the Interstate Commerce Commission in connection with its order calling for a redistribution of freight cars, to the effect that automobile cars should be returned to their home lines. Unless we can get some action in this matter it is probable that many car factories will have to suspend operations for a time at least."

—

Freight Car Shortage Necessitates Urgent Relief

NEW YORK, Dec. 4—Nation-wide redistribution of box cars is required by a new order agreed upon by the railroad conference committee on car efficiency in its campaign to relieve the car shortage which is seriously holding up freight in all parts of the country. By this order box cars will be diverted from parts of the country where they are not needed, to the West, Northwest, South and Southwest, where there is urgent need for them. The instructions issued refer to box cars, loaded or empty.

As an emergency measure the railroad authorities at Washington have authorized the railroads to establish and maintain until May 1 a new progressive demurrage scale higher than the present flat rate of $1 a day. Under the new scale 2 free days are allowed, and subsequent charges are $1 for the third, $2 for the fourth, $3 for the fifth day, and $5 for the sixth and each day thereafter.

Apropos of the redistribution plan, railroads in New England are to turn over to their Southern and Western connections 30 per cent more box cars than they receive from those lines. Railroads in what is known as the trunk line and central freight territory, regardless of the number of box cars on their lines, must deliver to their Southern and Western connections 20 per cent more box cars than received from them.

—

Car Shortage Felt at Flint

DETROIT, Dec. 4—The Chevrolet Motor Co. has been forced to double deck the ordinary freight cars, shipping cars in many pieces in order to load them, and putting six cars in a freight car instead of three as ordinarily, in its efforts to overcome the freight car shortage. Every automobile maker in Flint is suffering from the shortage. Incoming freight shipments are piled up at the various freight receiving sheds. Railroads are making every effort to relieve the congestion.

—

November Jeffery's Biggest Month

KENOSHA, WIS., Dec. 2—During the first 3 months of the Nash Motors Co. régime, all sales records have been broken. November was the biggest sales month in the history of the company. During that month, its books showed an actual increase of 381 per cent over the corresponding month last year.

—

Batavia Rubber Complains of Discriminating Freight Rates

WASHINGTON, Dec. 6—The Batavia Rubber Co., Batavia, N. Y., has filed complaint with the Interstate Commerce Commission charging the Atlantic Coast Line Railroad, and connecting lines, with discrimination in rates with respect to its articles of manufacture on shipments meant for so-called Southern Classification territory by way of Ohio River crossings.

The complaint alleges that this discrimination extends to classes of tires as follows:

First class, on pneumatic tires, in any quantity; second class on solid tires, any quantity; and, first class, on all others, such as tires in steel casings.

The complainant asks the commission to order rates which will cause "a larger spread" between the carload, and less than carload lots.

Goodyear Profits $7,003,330

Sales During Company's 1916 Fiscal Year Total $63,950,399

AKRON, Dec. 6—Sales of $63,950,399.52 during the past year are reported by the Goodyear Tire & Rubber Co., this city, in the year ending Oct. 31, 1916. This compares with $36,490,651.64 for the preceding year. Net profits were $7,003,330 as against $5,189,528 for the preceding year. There remains an unappropriated surplus of $2,253,166.87. Cash dividends during the year amounted to $764,239.28 on the preferred and $1,261,332 on the common. Stock dividends amounted to $8,427,000. To meet the demand for its products, the company added more fixed capital, which was provided for by the sale of $17,500,000 of preferred, having previously retired $6,650,000 of preferred then outstanding. A stock dividend of 100 per cent out of accumulated surplus was distributed, after paying the regular cash dividends, 7 per cent on the preferred and 12 per cent on the outstanding common.

In its balance sheet the company shows total assets amounting to $49,217,794, total liabilities of $9,167,973, thus leaving an excess of assets over liabilities of $40,049,820.

—

Reo Drives 70 Per Cent of Cars

LANSING, MICH., Dec. 4—The Reo Motor Car Co. is driving more than 70 per cent of its output to dealers within a radius of 1000 miles in order to overcome the scarcity of freight cars, and up to the present has been fortunate enough to escape great hardship. The company plans to use flat cars when severe Winter weather prevents driving.

—

Post Tire Buys Plant

ST. LOUIS, Dec. 2.—The Post Tire and Rubber Corp, recently incorporated for $1,500,000, has bought the plant of the Union Tire & Rubber Co., this city, and will immediately begin operations. The plant consists of a two-story brick structure with a total floor space of 70,000 sq. ft.

—

Grant Moves to Cleveland

CLEVELAND, Dec. 1—The Grant Motor Car Corp. marks the opening of its fourth year of growth, by removal from Findlay, Ohio, to its great new factory at Coit and Kirby Avenues, Cleveland.

The new Grant home is a model of modern efficient factory construction

and arrangement. The length is 600 ft.; the width 250 ft., and the floor space, 150,000 sq. ft. It has an annual capacity of 35,000 cars.

The factory is a unit. Every department, while separate, and distinct, is within easy access of the other departments with which its work is closely connected. The car while building passes from department to department quickly. By means of a conveyor system, the final car assembly may be completed in less than 10 min. The factory stands on a 7-acre tract.

—

Apperson in New Factory

KOKOMO, IND., Dec. 4—The Aperson Bros. Automobile Co., this city, has just finished moving into its new group of factory buildings. Its plant is modern in every respect.

—

Turnbull Wagon Adds Bodies

DEFIANCE, OHIO, Dec. 4.—The Turnbull Wagon Co. has added an automobile body department. This will be operated independently of the wagon factory.

—

Dorris Discontinues 1500-Pounder

ST. LOUIS, MO., Dec. 1—The Dorris Motor Car Co., this city, has discontinued the manufacture of its 1500-lb. delivery wagon.

—

Fitch, Tractor Inventor, Dead

BIG RAPIDS, MICH., Dec. 2—John H. Fitch, inventor of the four-drive tractor and president of the Four Drive Tractor Co., Inc., Big Rapids, died Nov. 24, after a brief illness. His office is filled automatically by E. J. Jenkins, who will continue also as general manager.

Timken Co-Operative Store

Employees of Axle Company Organize to Secure Benefits of Wholesale Prices

DETROIT, MICH., Dec. 1—Employees of the Timken-Detroit Axle Co. have organized a co-operative store for the purpose of reducing the high cost of living. For the present the store benefits will be confined to married employees, but it is planned to enlarge the establishment in the near future so that any employee may participate. Married employees will, temporarily, have to be in the employ of the firm for 6 months to be eligible. Outsiders will never be allowed to make purchases in the store.

The business will be operated entirely by employees though sanctioned and furthered by the company. L. R. Judson, head of the welfare department and temporary chairman and manager of the store, originated the idea. His first step was to write a letter to each of the eligible workers, asking them if they would like to save from 7 to 8 cents a pound on coffee. The letter was sent to feel out the employees on the subject and they were given 1 day to respond. More than 250 lb. were ordered and the plan saved the employees the amount promised, thus effectually giving the scheme its needed impetus.

A temporary structure is being erected to be used for the store and a permanent one will be built later. Orders have already been filled for tea, saving 14 cents on a 50-cent brand, and on apples saving 20 cents on a regular $2 grade. Canned goods, butter, eggs, corn meal and other staples will also be sold. A large saving on everything will be effected.

The store will start with 200 employees for membership and includes in its organization L. R. Judson, chairman and manager; G. W. Veal (assistant to general manager), acting secretary and treasurer, and W. R. McKay (superintendent), E. Rutter (material superintendent), and G. E. Holmes (carpenter foreman), executive committee.

Studebaker Plans 200,000 Car Output

DETROIT, Dec. 5—The Studebaker Corp. is making plans for a production of 200,000 cars yearly and the employment of 20,000 men, with an aggregate yearly business of $100,000,000, within the next 2 years. The company employs 8000 workers at present.

—

Buick Builds 563 Cars Daily

FLINT, MICH., Dec. 5—The Buick Motor Co., this city, has been turning out 563 cars daily in the past 8 working days. During November, 10,430 cars were shipped and 10,700 manufactured.

—

Stout Plans Aeroplane Clubs

DETROIT, Dec. 4—W. B. Stout, manager of the aircraft division of the Packard Motor Car Co., plans to organize model aircraft clubs in all of the Detroit high schools. Mr. Stout organized a similar club in Chicago under the name of the Model Aero Club of Ill. The organization developed aeroplanes from models. It is planned through the new club to be organized here, to bring all of the different Detroit organizations interested in aviation together annually in competition.

Aviation Experts Gathered Together on Joy Field

This illustration is from a photograph taken at the Aviation Field owned by Henry B. Joy of Detroit. The field is located near Mt. Clemens, Mich., on the shores of Lake St. Clair. Squier, Officer in Charge of Aviation; Eugene Lewis; Dr. W. Stratton, Director of Bureau of Standards; Henry Souther, Consulting Engineer United States Army; Dr. Charles F. Marvin, Chief of Weather Bureau, Washington, D. C.; Howard E. Coffin; S. D. Waldon; Lieut. W. G. Child, United States Navy; Roy D. Chapin; Dr. Charles D. Walcott, Sec. Smithsonian Institute, and Russell Huff

Is Scare Advertising Potential?

W. B. Lashar, of Weed Chain, Advances Arguments in Favor of Such Copy

NEW YORK, Dec. 1—Whether scare advertising copy is potential copy or not is a question that may be settled in the not distant future. When the National Automobile Chamber of Commerce, Inc., appointed its committee to discourage scare advertising, one of the concerns it had in mind was the American Chain Co., manufacturer of Weed anti-skid chains. Walter B. Lashar, president of this concern, has taken up the defense of scare copy on the ground that it is positive advertising rather than negative, and he believes his advertising thus performs a public service.

One of the pertinent examples cited by Mr. Lashar is that a manufacturer of fire extinguishers that have real merit, who puts out scare copy does not thus make people give up living in houses, but makes them more keen for fire-proof construction. Mr. Lashar asks the question: "Does such copy make people scoff at the dangers of fire, make them more reckless than ever, or does it bring home to the individual a vivid realization of a fire in his home and make him insist that every possible precaution be taken to prevent fires?"

Continuing his arguments in favor of scare copy, Mr. Lashar says:

"Scare copy is like any other copy; it can be good or bad or merely negative. There is only one standard by which 'scare' copy can be judged: The criterion is not what it does *to* the public but what it does *for* the public.

"If scare copy plays upon the credulity, the superstition, the helplessness, the cupidity of people, merely to coin these weaknesses into money without regard to the harm that is being done; if this copy is a lie in spirit or in fact; if it increases real suffering and misery, by dwelling upon an evil for which there is no prevention and no remedy—then it is a crime to use such copy. But scare copy that is true, that brings home to each individual a consciousness of his own personal responsibility for a real evil that is a constant menace—a reality that exacts a frightful toll in human lives and in human suffering—and points out a direct and effective remedy that ordinary intelligence can use, such scare copy is doing a great public service.

"It is true that this 'scare' copy may make a few hundred neurasthenics a little more miserable, but the real evil is in the neurasthenia, not in the copy. The logical effect of this scare copy is to make a thousand people more careful to safeguard against troubles. The measure of the worth of such copy has not its effect upon a relatively small group of people but its effect upon the public as a whole.

"The manufacturer uses scare copy because it sells his product. Selling is the most important factor in his business. A manufacturer whose selling plan makes money for himself, and at the same time is of great and definite benefit to the public, including the part of the public that does not buy his product, seems to me to be a more real philanthropist, a more valuable philanthropist than one who gives a certain sum of money for a particular work.

"The simple truth is that scare copy is the only kind that jars some of us out of our complacent self-sufficiency, our fixed habits of carelessness, our blind delusions, that we will get through somehow, our disposition to take a gambler's risks."

Mr. Lashar finishes with the following: "These are some of the reasons why we continue to use intelligent, constructive scare copy, the object of which is to make motoring safe and secure, under all road conditions, for all those who use the road, whether they travel in cars, on foot, or by horse. So long as scare copy benefits the public infinitely more than it can profit any company, such a company can afford to let any interest that feels itself antagonized by such copy fight out the issue with the public."

—

Moto-Meter Enjoins Heat-Ometer

NEW YORK, Dec. 1—A preliminary injunction prohibiting sale of the Heat-Ometer radiator indicator and use of the word Heat-Ometer has been granted on complaint of the Moto-Meter Co., Inc., maker of the Boyce Moto-Meter. Suit was brought against the Times Square Automobile Co., which had been selling Heat-Ometer, the Moto-Meter Co. alleging that the device infringed its product and that the use of the word Heat-Ometer infringed the trade mark Moto-Meter.

The Heat-Ometer, made by the Heat-Ometer Co., Inc., New York, consists of a diamond-shaped frame holding a glass indicator tube containing a sensitive liquid which is pink at normal temperature but turns deep purple when a dangerous degree of heat is reached. Like the Boyce Moto-Meter, the Heat-Ometer is mounted on the radiator cap. The suit was in the U. S. district court for the southern district of New York.

—

Ford Suit in Judge's Hands

DETROIT, Dec. 1.—The suit instituted by Dodge Bros. against the Ford Motor Co. to restrain the latter from further expansion is now in the hands of the judges, who have taken the case under advisement for an early decision.

70% of Accidents at Crossroads

Sec. of State Hugo, of N. Y., Finds Fatalities Measured by Driver's Carelessness

ALBANY, N. Y., Dec. 2—That approximately 70 per cent of fatal automobile accidents are due to careless driving at street and road intersections, according to the coroner's report, is pointed out by Secretary of State Hugo, who has made a study of the traffic conditions accompanying such accidents.

There seems to have been little difficulty where cars travel along intersecting roads of unequal importance, owing to the established custom that the car on the less important road must approach the main highway with special caution, a practice expected by those moving rapidly on the more important thoroughfare. The real difficulty arises when crossroads are of equal importance with the result that drivers approach rapidly from both directions, each considering himself entitled to the exercise of caution by the other driver. There seems to be an increase in the number of instances where misunderstandings based on reasoning of this kind leave the driver to take chances by approaching intersections at high speed. Though the law requires drivers to slow down and signal for crossroads comparatively few observe these rules, thus enhancing the risk of accident. Secretary Hugo considers that too great reliance is frequently placed by automobilists on the power of their brakes to stop their cars quickly. This is unwise, he says, because the driver may, and frequently does, misjudge his speed and other surrounding conditions.

More Care Required

Dangerous crossroads or those of congested area are usually protected by traffic police during the daytime. After these hours, however, these points present problems in accident prevention which are constantly growing more difficult with the increasing number of automobiles and other vehicles traveling these thoroughfares.

Unless some steps are taken to compel all drivers to approach crossroads of equal prominence with the greatest care, Secretary Hugo fears that accidents of this kind will become more frequent and more serious. Warning signals might provide a certain amount of protection at such points, although these are not sufficiently effective in all cases, particularly, as there is nothing to prevent deaf persons from operating cars. The only satisfactory solution of the problem is the use of care by each individual driver when approaching such intersections.

Denmark Likes U. S. A. Cars

Consul General Winslow Reports Demand for Cars and Trucks Increasing

NEW YORK, Dec. 4—The automobile business in Denmark is in a brilliant condition at the present time, according to E. D. Winslow, consul general of the United States to Denmark. Mr. Winslow has returned only recently from that country and states that the demand for cars in that country has increased to such an extent during the past 2 years that the supply is entirely inadequate. People are prosperous on account of the high prices paid for their products due to the war, and the excellent road conditions and attractive touring possibilities of the country naturally make the purchase of a car the logical sequence.

Motor trucks have never before been in as great demand in Denmark as at the present time since the unusually high prices paid for horses by the belligerant nations have induced a very large percentage of the horse owners to part with their animals. Since the labor thus lost must be made up, motor trucks are being bought in large numbers to do the work formerly performed by the horses. On the farms the use of motor tractors has increased rapidly and it is very probable that these machines will be in still greater demand in the future.

The obnoxious laws, which formerly limited automobile touring in Denmark, have either been repealed or so modified that it is now possible to travel throughout the country just as freely as in other lands.

Most Cars Represented

Most of the leading American car manufacturers are now represented in Denmark and Mr. Winslow recommends that any car or accessory maker desirous of entering the Danish field secure special agents. There are now more dealers in Denmark than ever before, about fifty being located in Copenhagen. The people have taken kindly to American cars and accessories and at the present time our manufacturers have this market almost to themselves. If the quality of the American products is maintained and the service rendered by the manufacturers' representatives is satisfactory, this market should be continued after the war.

Very little data can be secured at present in regard to automobile imports into Denmark. The only statistics available, those for the years 1912 and 1913 appearing in tabular form below are in the form of weight of cars, chassis and parts in pounds, trucks not being segregated. These statistics serve to indicate how small these imports were before the beginning of the war.

Imported Into Denmark

COMPLETE CARS

From	1913 Lb.	1912 Lb.
Germany	979,000	765,380
Great Britain	264,000	214,500
Sweden	43,780	10,340
Belgium	36,960	7,480

To Raise Fire Insurance Rates

NEW YORK, Dec. 5—Automobile fire insurance rates will advance about 10 per cent Jan. 1. The new schedule has been issued by the Eastern and New England Automobile Underwriters' Conferences. In addition to this slight advance, policies will now be written under the non-valued plan, either with or without the theft clause. Heretofore this has not been possible. Policies under the valued plan will include the theft clause as usual. No car can be insured for more than its cost to the owner.

Wants U. S. A. Ideas

LONDON, ENGLAND, Nov. 15—At the last meeting of the Institution of Automobile Engineers, Mr. A. E. Berriman of the Daimler Co., made the suggestion that endeavors should be made to obtain each session a paper from a leading American automobile engineer, giving the latest views on designs, etc., in the United States. This was in discussion following the reading of a paper on American lighting, starting and ignition systems.

Cadillac Co. Starts Suit

DETROIT, Dec. 1—The Cadillac Motor Car Co. has started suit against the Cadillac Auto Truck Co., Cadillac, Mich., asking for an injunction restraining the latter firm from using the name Cadillac or Cadillac Auto Truck Co. or any other name prejudicial to the interests of the Detroit concern.

Electro-Pneumatic Gearshift

New Company To Erect Plant in Pittsburgh for Its Manufacture

PITTSBURGH, Dec. 4—The Electro-Pneumatic Gearshift Corp., of this city, has announced its intention to erect a plant for the manufacture of an electro-pneumatic gearshift. The actual power for shifting the gears is supplied by compressed air and contained in a reservoir and fed by a pump driven off the timing gears, there being an automatic valve for cutting in the pump when pressure falls below a predetermined amount. The air is used also for operating the clutch so that all the driver has to do is to move the switch lever mounted on the steering column.

It is stated that the magnetic operation of the valves controlling the air is such that the gears and clutch can be operated at any speed desired. This should eliminate the shock which would be bound to occur if the clutch were engaged automatically always at the same speed. It allows for smooth starting and it also enables the driver to differentiate between a change up and a change down on the gears, operations which should not be performed with quite the same celerity.

The inventor is John J. MacPherson and the company has been formed with M. F. Metcalf president and Joseph C. Baird, secretary and treasurer.

$10,000 for Fuel Research

NEW YORK, Dec. 1—A $10,000 prize for fuel research will be given by the Aero Club. By the will of the late S. H. Valentine, formerly Governor of the Aero Club of America, this sum has been given to the club to establish a prize, or prizes, for the encouragement of aircraft, which shall not use gasoline as a fuel. Mr. Valentine's bequest is expected to stimulate interest in the discovery of a new fuel, lighter than gasoline, which will make longer flights possible.

Richardson Chalmers Advertising Mgr.

DETROIT, Dec. 6—C. S. Richardson has been appointed advertising manager of the Chalmers Motor Co., this city. He was formerly with the Mahin Advertising Agency.

Travers Nash Advertising Mgr.

DETROIT, Dec. 6—E. J. Travers has become advertising manager of the Nash Motor Co., Kenosha, Wis. He was formerly with the Chicago *Herald*.

Winton Chauffeurs Get Prizes

25 Drivers Total 290,426.7 Miles at Repair Cost of $5.90

CLEVELAND, Dec. 6—The Winton Co., this city, has awarded chauffeurs $3,500 in prizes in its annual contest for those who drive Winton cars the farthest with the least repair expense. This year twenty-five chauffeurs drove their cars a total of 290,426.7 miles at a total repair expense of $5.90. George Felt of Minneapolis, chauffeur for H. D. McCord, won first prize, $500. W. C. Ball of Kalamazoo, chauffeur for F. F. Rowe, was awarded second money, $400. Alfred Shibley of Pittsburgh, driving for J. W. Lloyd, and W. M. Newsome of Atlanta, driving for M. R. Hirsch, won third and fourth prizes, respectively, $300 and $200. Prizes of $100 were awarded to the following:

A. H. Klein, chauffeur; S. J. Wilkins, Chicago, owner of car.
Ralph H. Lee, chauffeur; S. J. Franklin, Millville, N. J., owner of car.
G. M. Lewis, chauffeur; E. R. Caldwell, owner of car.
Henry Belanger, chauffeur; Mrs. D. B. Curtis, Manchester, N. H., owner of car.
George T. Macone, chauffeur; F. E. Coursen, Stockbridge, Mass., owner of car.
Thomas Murren, chauffeur; J. M. Anderson, Boston, owner of car.
Joseph Castellucci, chauffeur; Mrs. M. E. Bearse, West Medford, Mass., owner of car.
Edw. M. Armstrong, chauffeur; C. M. Godnow, Boston, owner of car.
Robert Clements, chauffeur; F. H. Jones, Andover, Mass., owner of car.
P. O. Hale, chauffeur; A. P. Friend, West Newton, Mass., owner of car.
F. H. Coyston, chauffeur; W. L. Porter, Pittsburgh, owner of car.
T. L. Quigley, chauffeur; J. J. Flanagan, Elmira, N. Y., owner of car.
Herbert Lewis, chauffeur; George Spottiswoode, Orange, N. J., owner of car.
Chris McDermott, chauffeur; Robert Fraser, Utica, N. Y., owner of car.
P. J. Farrington, chauffeur; M. H. Hellman, Los Angeles, owner of car.
Charles Schmidt, chauffeur; Thomas Lonergan, St. Louis, owner of car.
W. Desillier, chauffeur; Allen Arnold, Swampscott, Mass., owner of car.
W. L. Woods, chauffeur; Miss H. J. Silver, Brooklyn, owner of car.
A. P. Holst, chauffeur; Mrs. John Sexton, Chicago, owner of car.
E. P. Carey, chauffeur; William de la Barre, Minneapolis, owner of car.
Albert Hitchen, chauffeur; C. W. Tabor, Los Angeles, owner of car.

More interesting than the report for any single year are the grand totals for the entire period during which contests have been conducted—9 years, as follows:

Number of cars that traveled 5000 miles or more each	536
Total mileage made by these cars	5,509,049.3
Average miles per car	10,278
Total repair expenses for all cars	$5,640.64
Average repair expense per car	$10.52
Average repair expenses per car per 1000 miles	$1.03

Or less than 1-9th of 1 cent per mile.

The total distance traveled by these Winton Six cars, every mile of which was sworn to by both the car owner and his chauffeur, is greater than would be traveled on 220 tours around the earth at the equator. Five and one-half million miles certainly constitute an exhaustive test of the standing-up qualities of a motor car. And the average repair expense indicates that a Winton six owner traveling 25,000 miles per year would encounter repair expenses of $25.75 per annum.

—

Detroit-Wyandotte Sells Stock

DETROIT, Dec. 1—The Detroit-Wyandotte Motor Truck Co. is selling its unissued treasury stock for the purpose of securing a larger working capital. The concern is going into foreign markets and is making shipments to Porto Rico and Cuba.

—

Steel Prices Higher

NEW YORK, Dec. 5—This week's market activities were featured by the expected rise in steel. Both Bessemer and open-hearth rose $2.50 a ton to $55. Lead rose 45 cents per 100 lb. to $7.75. Kansas crude petroleum went up 10 cents a barrel on Thursday to $1. Rubber prices are higher, Para quoting at 79 cents a pound and Ceylon at 74½ cents.

The further rise of rubber will probably hasten the long-expected rise in tire prices, which, it has been reported, will probably go up in the early part of 1917.

Tin dropped to $45 per 100 lb., a net loss of 25 cents. Rapeseed oil rose 3 cents to 98 cents a gallon. Linseed oil dropped 3 cents a gallon to 93 cents.

1% Extra Chandler Dividend

Earnings for Year Estimated at $1,715,000 or $24.50 Per Share

CLEVELAND, Dec. 5.—The Chandler Motor Car Co. has declared an extra dividend of 1 per cent in addition to the regular 2 per cent quarterly distribution, both being payable Jan. 2 to holders of record Dec. 18.

The company is earning approximately $24.50 per share this year, or around $1,715,000. Shipments of cars for 1916 are 115 per cent greater than in 1915, and orders now actually signed up amount to 20,381 cars.

It has been officially estimated that in 1917 net earnings should exceed $2,800,000, which would be equal to $40 per share. The net earnings this year, $1,715,000, allow a surplus of over $1,000,000, after the payment of the 10 per cent dividends which have been declared since Jan. 1.

Chandler shipments in October were four and a half times larger than a year ago; four times greater in November, and will be six times greater in December.

An important factor of the Chandler situation is that its dealers are without cars and are urging deliveries.

—

Dividends Declared

Kelly-Springfield Tire Co., quarterly of 1½ per cent on 6 per cent preferred, payable Jan. 2, to stock of record of Dec. 16.

Edmunds & Jones Corp., $1 a share on the common and the regular quarterly dividend on the 7 per cent preferred, both payable on Jan. 2. This is the third dividend the corporation has declared since March 30, 1916.

New Directors Proposed for Pierce-Arrow

BUFFALO, Dec. 5.—The transfer of the Pierce-Arrow property from the present company to the Pierce-Arrow Motor Car Corp. will be made to-morrow, when the new organization takes hold, under the presidency of Colonel Charles Clifton.

It is proposed to make the following persons directors of the new organizations: Charles Clifton, president; Henry May, vice-president; W. J. Foss, Buffalo; J. F. Alvord, president of the Torrington Co.; W. S. Cox, of J. & W. Seligman & Co.; C. J. Schmidlapp, vice-president of the Chase National Bank; J. G. Dudley, of Buffalo; Albert Strauss, of J. & W. Seligman & Co., and C. H.

McCullough, vice-president and general manager of the Lackawanna Steel Co., Buffalo.

The company was recently chartered in this State under the name of the Pierce-Arrow Motor Car & Truck Co., with 350,000 shares of capital stock, 100,000 shares of preferred, par $100, and 250,000 shares of common with no par value. The incorporators were L. D. Adkins, R. J. Trimble and E. S. Hemphill.

—

Crow Likes Old Name Best

ELKHART, IND., Dec. 4—The Crow Motor Co., this city has changed its name to the Crow-Elkhart Motor Co. The company announced only a few weeks ago that its name had been changed from the Crow-Elkhart Motor Co. to the Crow Motor Co., and now the old name is effective again.

—

Ford Tractor Capital Now $10,000,000

DOVER, DEL., Dec. 1—The Ford Tractor Co., Ltd., has filed a certificate changing its name to the Ford Tractor Co., Inc., and increasing the capital stock from $1,000,000 to $10,000,000. The company was first incorporated here Nov. 8, 1916.

—

Porter Rubber Doubles Capital

SALEM, OHIO, Dec. 1—The Porter Rubber Co. will increase its capital from $125,000 to $250,000, to permit expansion and the probable construction of another plant.

Motor Issues Are Lower

General Motors Only One to Show Strength with a Gain of 140 Points

NEW YORK, Dec. 6—The automobile and accessory securities are at present in an apathetic market with a corresponding decrease in value. General Motors, with a gain of 140 points, was the only security to show strength. Last week, this stock declined 90 points on a fluctuating market. Fisk first preferred regained the 9 points lost the previous week by jumping 10 points to 110. Packard preferred gained 3 points.

Chevrolet declined 7 points more this week, making a total of 11 in two weeks. Firestone common dropped 6 points. Studebaker common went down 4 points more to 120 and Willys-Overland common 2⅛ points to 36⅜.

Quotations on the Detroit Stock Exchange were a little higher this week with gains ranging from a fraction to 4½ points. Studebaker common dropped 6⅛ points in sympathy with the New York quotation. It is reported in Detroit that United Motors stock will soon be listed on the New York Exchange.

—

Control Three Tire Companies

COSHOCTON, OHIO, Dec. 5.—The interests who took over the plant of the McClurg Rubber Co. at Coshocton, Ohio, have organized a number of corporations, among which are the Midland Tire & Rubber Co., the Ben Hur Tire & Rubber Co. and the Peerless Tire & Rubber Co. The plant, which is now in operation, will be conducted by the Midland Tire & Rubber Co. The other corporations were chartered in order to preserve the names of the Peerless and Ben Hur tires, which were formerly manufactured at the local plant.

—

Pennsylvania Crude Reaches $2.75

NEW YORK, Dec. 6—Pennsylvania crude oil was advanced 15 cents yesterday, making $2.75 a barrel paid producers, the highest price ever reached in the history of the oil industry. A year ago when oil prices went beyond the expectations of producers the price was $2.50 and $3 oil was predicted.

—

Milwaukee Gasoline Up 1½ Cents

MILWAUKEE, Dec. 2.—Gasoline prices on the so-called 65-deg. test were advanced 1½ cents per gallon, and on the 70-deg. test 2 cents per gallon, by all oil companies operating in Milwaukee, on Dec. 1. The prices on the lower tests are undisturbed from the last change, effective Oct. 11.

—

Parker Rust-Proof Issues Stock

DETROIT, Dec. 4—The Parker Rust-Proof Co. has authorized a capital stock issue of $600,000 7 per cent cumulative preferred stock—non-assessable, and $1,700,000 common stock—non-assessable. The present price of the stock is $100.

Frontenac Wins at Uniontown

Race Marred by Death of Three in Accident—Winner Averages 102 M.P.H.

UNIONTOWN, PA., Dec. 2—The first race meet on the local speedway to-day was marred by a sad accident in which three were killed. Hughie Hughes, driver of the Hoskins, and Frank Galvin and his mechanician, Gaston Weigel, were killed when Galvin's Premier swerved in front of the pits and side-swiped one-quarter of the press stand, where Hughes was standing. Hughes and Wiegel were instantly killed and Galvin died later. That to-day's race was under the spell of a hoodoo is manifested in the fact that two others were killed a few days before the race when C. M. Heist and F. E. Bush were killed while in practice after they had been ordered off the track. The car struck the wall at the top of the speedway and went through. The accident was due to a crystallized axle.

That the accidents are not the fault of the new 1⅛-mile board speedway makes the death of five appear all the more under the spell of a hoodoo. The track was in good condition and fast.

Hughes in to-day's 112½-mile race was going at 91 m.p.h. when he pulled up on the Pugh car, which was going slowly, and in order to avoid hitting it Hughes ran his car through the guard rail and out into the field in the center of the track. He then went to the pits and was standing beside his car in front of the press stand, when Galvin's car, going nearly 100 m.p.h., suddenly, through some fault of the brake or wheel, swerved into him and the press stand.

Fully 21,000 people saw the races, the main event being won by Louis Chevrolet in a Frontenac, his time being 1:14:12 for 112½ miles, or 102 m.p.h.; Lewis, in a Premier, was second in 1:16:36½; De Palma, in a Mercedes, was third in 1:17:56 1-5, and Newgard, in a Crawford, fourth in 1:25. First prize was $1,000, second $700, third $500 and fourth $400.

The second race, a 54-mile event for dealers, was won by N. P. Fetterman in Peerless in 40:18. M. F. McCarthy in Murray second and H. L. Robinson in Haynes third.

Hughie Hughes, killed to-day, was an English racing driver. He came to the United States 10 years ago, and recently made his home here. Hughes is of the old school of automobile drivers. In 1904, in France, he drove a De Dietrich in the Gordon Bennett race. In 1911 he won the Savannah Trophy race in a Mercer. The same year saw him third in the Grand Prize race in an Ono. He won the Tacoma Potlach contest in 1914, driving a Maxwell. He also won several hillclimbs with the Allen-Kingstons. He took Christie's front-drive car and drove it 110 m.p.h. at Indianapolis. He was a member of the British Aviation Corps and was 31 years old.

Resta Confirmed as Champion

NEW YORK, Dec. 5—The champion automobile racing driver of 1916 is Dario Resta. The contest for points in the American Automobile Assn. championship standing closed with the running of the 150-mile race at the Ascot Speedway, Los Angeles, on Thanksgiving Day. Resta with his total of 4100 points has a lead of 660 points over Aitken, his nearest rival, and he will be officially crowned by Chairman Kennerdell of the A.A.A. Contest Board at a dinner scheduled in Chicago on Feb. 1 under the auspices of the Chicago Automobile Club.

When it was announced last spring that the American Automobile Assn. would officially designate the 1916 champion the Bosch Magneto Co. immediately offered to award a trophy and $2,000 in cash to the driver so selected, and $1,000 and $500 to the drivers ranking second and third in the final official standing. The B. F. Goodrich Co. added $10,000 to the purse thus created, to be split $5,000, $3,000 and $2,000. Resta will thus receive $7,000 and a cup, Aitken $4,000 and Rickenbacher $2,500.

There were fifteen races which figured in the championship standings and the number of points awarded each was governed by the length and character of entries.

The final scores of all drivers with a ranking in the 1916 championship standing follows:

Dario Resta	4100	George Buzane	210
John Aitken	3440	Eddie O'Donell	185
E. V. Rickenbacher	2910	Chas. J. Devlin	140
Ralph De Palma	1790	Arthur H. Klein	125
Earl Cooper	1405	Jack LeCain	120
Wilbur D'Alene	1120	Glover Ruckstell	100

Test Fisher Farm Tractors

INDIANAPOLIS, Dec. 6—Five experimental one-wheel farm tractors, of the type to be manufactured by the new company in which Carl G. Fisher is interested, are being tested to destruction with a view to improving the design, which should be completed March 15. It is planned to start production in July.

Stutz Finishes First at Phoenix

Delno, Winner of State Fair Century, Captures 100-Mile Track Race

PHOENIX, ARIZ., Dec. 1—R. H. Delno of Tucson, driving the same sixteen-valve Stutz with which he won the century grind at the State Fair Nov. 18, won the 100-mile Thanksgiving Day race at the State fair grounds yesterday in 1 hr., 38 min. and 29¼ sec. Delno's time was 4½ min. faster than in the State Fair race, which he won in 1:43:12. R. E. Lambert, driving a Spa, was second in the Thanksgiving contest, his time being 1:42:00½. Roy Meacham in a Mercer finished third in 1:46:12.

Mechanician Killed

W. M. Drennan of Oklahoma City, a mechanician, was killed almost instantly when the Hudson entry No. 5 crashed through the fence on the north turn while R. G. Armstrong, driver, was attempting to pass the car ahead. The accident, which occurred in the seventh lap, was caused by Armstrong swinging to the outside of the track in an effort to pass the car ahead, and as both right wheels went over the bank into the soft earth Armstrong and Drennan were hurled from the car. Drennan was thrown against a post, as the big racer crashed through sixty feet of fence. Armstrong's escape with slight injuries was miraculous.

Pete Thomason in a Ford finished fourth in 1:49:26 and Al Gladney's Overland fifth in 1:49:40. The performance of the Ford, which went 94 miles without a stop, was one of the features of the contest. Thomason threw a tire in the ninety-fifth lap, otherwise would have been in the money. Seven of the nine entrants were running at the finish.

A. A. A. Opens New Offices

NEW YORK, Dec. 2—The American Automobile Assn. is establishing a branch bureau in the Circle Building on Broadway near Fifty-ninth Street.

U. S. Cars Popular in Java

NEW YORK, Dec. 2—Of the 759 automobiles imported into Java for the first 6 months of this year, 668 cars came from the United States, fifty-three from Italy and thirty-two from the Netherlands.

Roads Built Under Federal Supervision

WASHINGTON, D. C., Dec. 2—Nearly 5,000,000 sq. yd. of roadway, the equivalent of 561.9 miles of road 15 ft. wide,

were constructed under the supervision of Federal road specialists during the last fiscal year, according to the annual report of the Office of Public Roads and Rural Engineering, of the U. S. Department of Agriculture, just issued. This is more than double the mileage so constructed in previous years. The roads constructed under supervision of the office include experimental roads, post roads, county roads, and roads in National Parks and forests.

Boston Show Space Sold

BOSTON, MASS., Dec. 2—Practically all the space for the Boston show which opens in March has been sold. Provisions may be made later to take care of a few late comers, but they will have to share space with someone else, and possibly go in the basement. The first floor will be given over entirely to cars, and the balconies will have the accessories. There will be more space available this year because the big dining room has been taken over for the next show and this will give a big slice of room. A small section of hallway will be used for a luncheon space.

Duesenberg Takes 150-Mile Race—Cooper Is Second and Pullen Third

LOS ANGELES, Nov. 30—Eddie Rickenbacher in a Duesenberg to-day won the 150-mile Championship Award Sweepstakes race on the 1-mile paved Ascot Speedway, the final event in the American Automobile Association's contest for the title of champion driver of America. His time was 2:18:15.5. Cooper in a Stutz was second, Pullen in a Mercer was third, and Ruckstell in a Mercer was fourth. Cooper ran out of gasoline ½ mile from the finish, but coasted to the tape. Attendance was 30,000.

Pullen led at the 50th mile, with Rickenbacher, Cooper, Ruckstell and the field following. Pullen's time was 42:55 for the 50 miles, an average of 69.9 m.p.h.

Pullen, Rickenbacher, Cooper and Ruckstell were bunched in the lead in that order at 100 miles. Pullen's time was 1:28:18, an average of 57.95 m.p.h.

There were twelve entries and $5,000 in prizes, divided into $3,000 for first, $1,250 for second, $500 for third and $250 for fourth.

17 Exhibitors for Salon

NEW YORK, Dec. 2.—There will be seventeen exhibitors at the thirteenth annual Automobile Salon, Jan. 2 to 10, in the grand ball room of the Astor. Though the number of exhibitors is one less than the high mark established in 1912, the number of cars will be about 40 per cent greater, as the balcony of the ball room is to be used for exhibiting the overflow.

The list of exhibitors contains one which has heretofore exhibited at the National Shows, the Locomobile Co. of America. The other exhibitors are: White, Brewster, Daniels, Isotta-Fraschini, Lancia, Murray, Navara, Phianna, Rolls-Royce, Simplex, Singer and S-S-E. Custom body builders include Brewster, Holbrook, Locke and Rubay. In addition to these exhibits there will be a half dozen of tires and accessories.

The exhibition of the Navara marks the debut in the automobile field of the Herreshoffs, of Bristol, Conn., prominent builders of racing yachts.

—

Fritz Leaves Motor Appurtenances

NEW YORK, Dec. 1—George Fritz of Malverne, L. I., has resigned as vice-president and sales manager of the Motor Appurtenances Corp., this city, handling the J & B products, Jiffy jack and Wondertone horns. He will announce his new connection in the near future.

—

Feeley Supt. Pittsburgh Maxwell Branch

DETROIT, Dec. 4—C. R. Feeley has been appointed superintendent of the Pittsburgh service branch of the Maxwell Motor Co.

France Heavy Buyer of U. S. A. Cars in October

(*Continued from page* 951)

997. Denmark is another country that did not appear in last year's returns, while in October of this year 342 cars, valued at $241,020, were shipped there. During the 10 months of 1916 the exports amounted to 1305 cars, valued at $955,432.

During the 10 months of last year four cars, valued at $2,800, were shipped to Germany. Since then that country has not figured in the export returns. Italy bought seven cars from this country in October last, the value of which was $7,517, while in October a year ago forty cars, valued at $25,887, were shipped there. During the 10 months' period the shipments increased from 210 cars, valued at $134,901, in 1915, to 244 cars, valued at $151,484, in 1916.

Shipments of cars to other European countries amounted to 301 cars, valued at $327,196, in October last, and to 3403 cars, valued at $4,194,615, during the 10 months of this year. Last year the exports amounted to 814 cars, valued at $1,920,176, in October, and to 7502 cars, valued at $20,003,140, during the 10 months' period.

One thousand and twenty-one cars, valued at $718,962, were shipped into Canada in October last, while in October of last year the number was only 189 and the value $202,552. During the 10 months' period the shipments increased from 5238 cars, valued at $4,154,137, in 1915, to 11,118 cars, valued at $8,025,079, in 1916.

S. A. Shipments Increase

The exports of automobiles to all South American countries in October, 1915, amounted to 383 cars, valued at $210,840, while during the 10 months of last year the exports amounted to 2464 cars, valued at $1,277,326. This year the returns show that 302 cars, valued at $195,512, were exported to Argentina in October, while during the 10 months of this year the exports amounted to 4258 cars, valued at $2,206,709. Shipments to other South American countries were as follows: Brazil, forty-four cars, valued at $33,046, in October, and 348 cars, valued at $232,860, during the 10 months. Chile, 195 cars, valued at $158,719, in October, and 1075 cars, $712,748, during the 10 months. Venezuela, thirty-six cars, valued at $23,781, in October, and 447 cars, valued at $284,316 during the 10 months. All other South American countries 113 cars, valued at $64,986, in October, and 816 cars, valued at $509,877, during the 10 months.

Large gains are noted in the exports to the West Indies and Bermuda, the shipments increasing from 267 cars, valued at $173,355, in October, 1915, to 665 cars, valued at $505,198, in October last, and from 2625 cars, valued at $1,478,360, during the 10 months of last year to 4704 cars, valued at $3,152,389, in 1916.

There was also a large increase in the exports to Australia, Asia and Oceania during the two periods under consideration. Detailed figures appear in the tabulation on page 951.

Ignition

IT seems rather remarkable that after so many years of development we should not yet have arrived at one, single, standard form of ignition for automobile engines. Yet this is really testimony to the automobile engineer's instinct never to be satisfied with what he has but always to want something better.

When the magneto came it was less reliable than the coil and battery, but for a short time only. Soon it was supreme. Then came the starter and its essential battery, so back once more to battery ignition and a general concentration of brains on the problems appertaining thereto; so that we have now battery ignitions which will do everything the magneto ever did, save only to supply their own motive force.

Ignition units of 1917 are vastly more refined in mechanical detail than they ever were before. The high-speed engine has found the weak spots in many a device, and the general redesign thus called for has led to the use of much better principles combined with better construction. The change has spread over several years, of course, but we have now a far wider choice of igniting mechanisms of high quality and great reliability than we ever had before.

Exactly what happens to the gas in a cylinder as a result of passing a spark through it is still unsettled. There is more than one scientific theory and various of the learned men of the world are still working on the problem. The things we may learn from these researches ultimately is the exact effect of different sorts of spark, different spark intensities, sizes and temperatures. Whether the construction of ignition apparatus will be affected when we do possess this knowledge cannot be said. It would certainly have been a help in the past, but cut and try methods have had such fine results that revolutionary changes are unthinkable.

Legal Confusion

A DECISION in the United States Supreme Court establishing the right of any State to tax non-resident automobile owners for the use of the roads opens up such possibilities of confusion that it throws into the spotlight once more the need for making automobile law a matter for the Federal Government.

Roads are a national asset. Easy transportation in the Far West affects prices in the Far East. Entirely apart from the military importance of roads, modern commerce demands that they be everywhere as good as possible.

The present situation with regard to road building is little short of absurd. The same questions are being debated over and over again by different legislatures. The same experiments in road building are being repeated many times in different States. There is an enormous wastage of energy, a prodigious throwing away of money.

The sums which have got to be spent in America in the next 20 years to provide a country with adequate roads are so great and the possibilities for waste of the present system so potent that common sense demands the centralization of authority as essential. It is the only way to get the work done properly and promptly.

Time was when a man's travels would rarely take him beyond the borders of his State. Then State boundary had a real meaning, which to-day it does not possess for the traveler.

100 M. P. H. on Roads

THE old saying, "a place for everything" is brought strongly to mind by the accident which marked the recent Grand Prize race held over the Santa Monica course. Road races over courses such as this are relics of the early days of the industry when speeds of 60 m.p.h. were something out of the ordinary and accidents were correspondingly less likely to be serious, but to-day when speeds of over 100 m.p.h. are possible on such courses an accident assumes possibilities hitherto inconceivable.

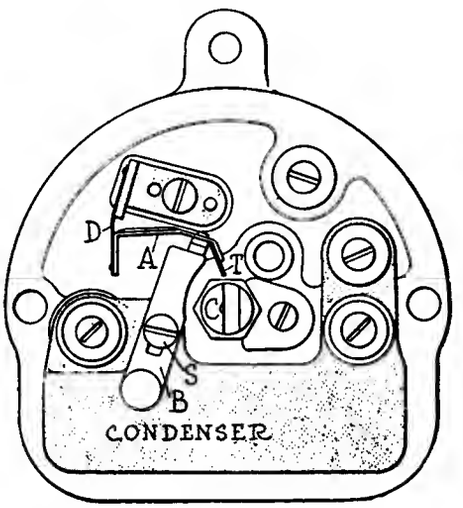
When it is realized that a 3000-lb. car traveling at 100 m.p.h. exerts approximately 2000 hp. at the moment of impact with a stationary body, and that the force of the blow is equivalent to that of a 1-ton weight falling through a distance of 500 ft., the killing of four persons, including the driver of the car, the serious injury of his mechanic and two other people, as well as the destruction of two trees and the car might be accepted as reasonably to be expected.

Ignition Is Much Improved

Battery Systems Are Stronger, More Durable and More Effective—Adjustments Are Easier and Replacement of Wearing Parts Simplified—Few Novelties in Magneto Construction

WITHOUT question the amount of development work done during the year with battery ignition systems has been such that the effectiveness of this form of ignition and its suitability for a permanent place on an automobile can no longer be doubted. The battery-vs.-magneto controversy is still with us, but there is every indication that it will remain in somewhat the same condition as the six versus four argument, and that the final analysis will show both magnetos and battery systems in continued use, each having its own definite sphere.

The real secret of a successful ignition device, whatever its principle, is the accuracy of its manufacture. A timing device, breaker or whatever it may be called, has to perform excessively rapid motions in quick succession and with extremely accurate spacing. Irregularity of operation renders the apparatus useless, and accuracy, especially at high speeds, can only be obtained by workmanship of an extremely high order of merit. Materials must be selected with great care and every process in manufacture watched and inspected with rigid adherence to the fine tolerances allowable. This means that it is a very difficult thing to make a good ignition distributer and coil or a good magneto, and it is only good ones that are any use. With greatly increased demand the ignition manufacturers have had to expand while beset with difficulties in getting the right materials and trouble in obtaining the requisite class of labor, but they have risen to the demand wonderfully.



Mechanism of the bearingless breaker of the Atwater Kent closed circuit system

So far as design is concerned, 2 years ago the coming of the high speed engine called for changes, but the ignition breakers operate to-day at much higher speeds than any engine requires; mostly the igniter is in possession of a capacity to ignite at a speed of from 500 to 1000 r.p.m. greater than the engine of any machine on the road.

Two entirely new systems have appeared recently, the Philbrin and the Pittsfield, both being quite different from any of the older varieties. Among the big producers, Atwater Kent has made the most prominent change by adding a closed circuit system, having previously made only an open circuit instrument. Connecticut, the closed circuit system with an automatic throw-out for the switch, should this be left on with the engine stopped, has been altered in detail but not in any principle. Remy, Westinghouse and Bosch, protagonists of the closed circuit, have made practically no changes, and the same is true of the many instruments produced in smaller quantities. A general bettering of mechanical detail is the chief thing noticeable.

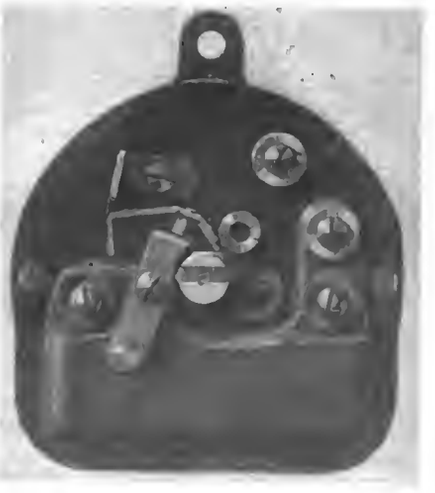
Atwater Kent Uses Closed Circuit

The closed circuit system which Atwater Kent will make in addition to its well known open circuit type is known as the CC and is quite different in construction from any other closed circuit distributer. Externally it is similar in appearance to the older model, and there are the same three units of distributer, coil and switch, but the similarity ends at this point.

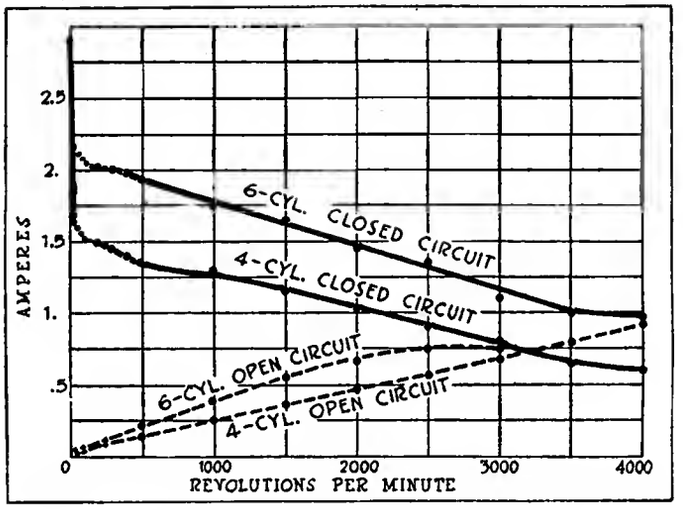
It is well known that the Atwater Kent Co. has one of the most up-to-date testing equipments for ignition devices, and it is mainly on the oscillograph and the current measuring instruments that this new ignition has been developed. The curves of current consumption for the closed and open circuit Atwater Kent igniters plotted side by side show that the difference at ordinary running speeds is quite small, and that the greater demand of the closed circuit only appears strongly at very low speeds indeed.

The most striking feature of the device mechanically, is its remarkable compactness and the use of a spring suspension for the breaker blade instead of a pin and socket or bearing of any kind. It would seem that the weight of the only

Atwater Kent closed circuit distributor with the coil mounted alongside



Six cylinder Atwater Kent type CC breaker mechanism



Comparative current consumption for the two Atwater Kent systems, the closed and open circuit types

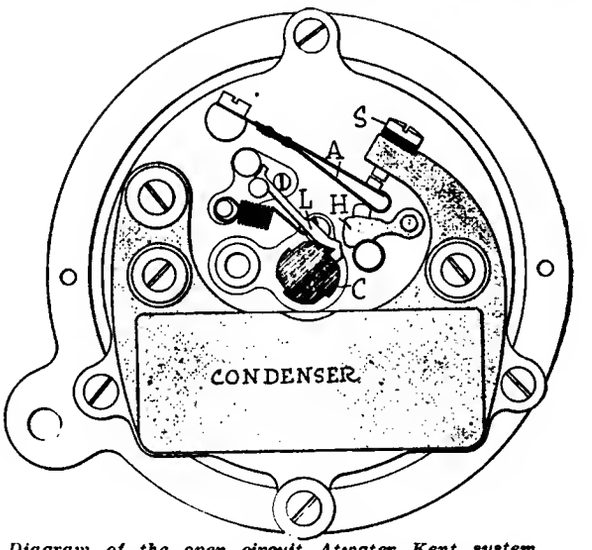


Diagram of the open circuit Atwater Kent system which has not been changed in design

moving part is as small as it could possibly be in any form of instrument, the object, of course, being to get rapid enough action for multi-cylinder engines and to eliminate lag almost completely.

The unit is built up on an iron base which carries the condenser also. The contact arm is a steel stamping tipped with fiber where it touches the cam, and is riveted to a short length of spring steel D which in turn is riveted to the block L. The distributer cover is Bakelite with the terminals molded in place. There is no wiping contact in the distributer, the air gap between the nickel alloy distributer blade and the terminals being 0.015—0.020 in.

The shape of the cam has been determined by the experiments which showed that even the slightest variation in the radius of the curved portions between the flats exerted a powerful influence on the character of the spark. In the four-cylinder cam the limits of tolerance across the corners is 0.002 in. and across the flats it is 0.0015 in.

The light weight of the contact arm is an important factor in the operation of the breaker. In addition to reducing wear to the minimum, it eliminates harmonic vibration and operates to intensify the spark at high speed. Another important point is that the contact is virtually in the center of the contact arm instead of one end, thus reducing inertia and increasing synchronism. Also, because of the location of the arm contact, the two points must come together absolutely squarely with reference to each other.

Revolution of the cam C brings its corners in contact with the fiber tip T of the contact arm A, thus separating the contacts and breaking the circuit. The contacts therefore are together for a considerable period, permitting the coil to be saturated thoroughly. The angular dwell, or the space during which the contacts of the four-cylinder instrument are together, is 47.9 deg. and the contacts open 0.006 in.

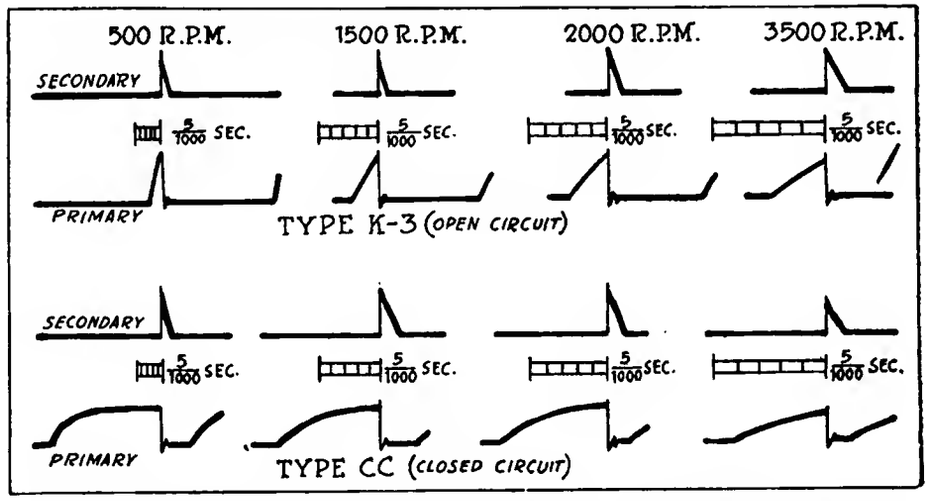
Tungsten is used for the contacts the one in the arm being forced in place, and there is but a single adjustment. To alter the size of the gap between contacts, the screw S is loosened and the arm B moved the required distance, this being slotted where the screw goes through.

Atwater Kent type K3 complete assembly

Owing to its proximity to the contacts the condenser requires to be only about one-sixth the size that would be required were it located in the coil container as has been previous practice. Furthermore the condenser in its new location now is instantly accessible, though cases where it is necessary to touch it are extremely rare.

The coils used for both Atwater Kent systems are practically alike except that the coil for the CC system carries a small series resistance for protection in case of very low speeds and in case the switch should be left closed with the engine stopped. These coils are slightly different from their predecessors as the primary and secondary windings are each continuous, instead of being in two sections each and this has permitted a slight reduction in the size of the unit. At present only hand advance is supplied though the instrument will be made with automatic advance.

The CC instrument is made in four-,



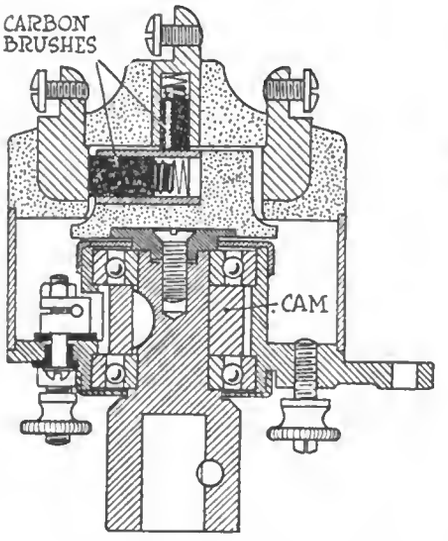
Oscillograms made with the two Atwater Kent systems run under the same conditions

six- and eight-cylinder types and the oscilligrams indicate that character and intensity of the spark up to speeds of 3500 r.p.m. are excellent.

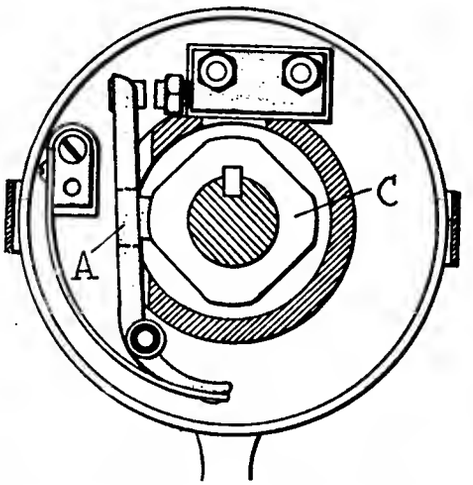
The open circuit, K3 instrument remains unchanged, except that the condenser has been located within the timer-distributer unit and in close proximity to the contacts. This has permitted a reduction in the size of the condenser and, at the same time, increased its effectiveness. In operation, rotation of the cam C draws the lever L forward until the movement of the cam trips the lever which in returning to its original position under the influence of a spring, strikes against the hammer H. The momentum of the hammer H striking the contact arm A instantaneously closes the circuit and opens it again. Here again the only part requiring adjustment is the contact, and even this should not need touching for 10,000 miles. To adjust the contacts the screw S is removed, the face of the contact dressed and one of the thin washers under the screw removed before the screw is returned to position. The standard automatic advance mechanism is provided for the K3 and it is made for four-, six-, eight- and twelve-cylinder engines.

No Change in Bosch Distributer

The Bosch battery ignition unit is modeled very much upon the magneto breaker and distributer. Rotation of the cam C presses a fiber block which brings the contacts together and a spring separates the contacts at the moment of ignition. Manually operated advance is provided. The distributer is mounted directly over the breaker and consists of the usual cover with the terminals molded in place. A radial arm carries a carbon brush which makes wiping contact with the terminals successively.



These two views of the Bosch timer-distributor show the very compact nature of the design and how access to the breaker is obtained by removing the distributor head

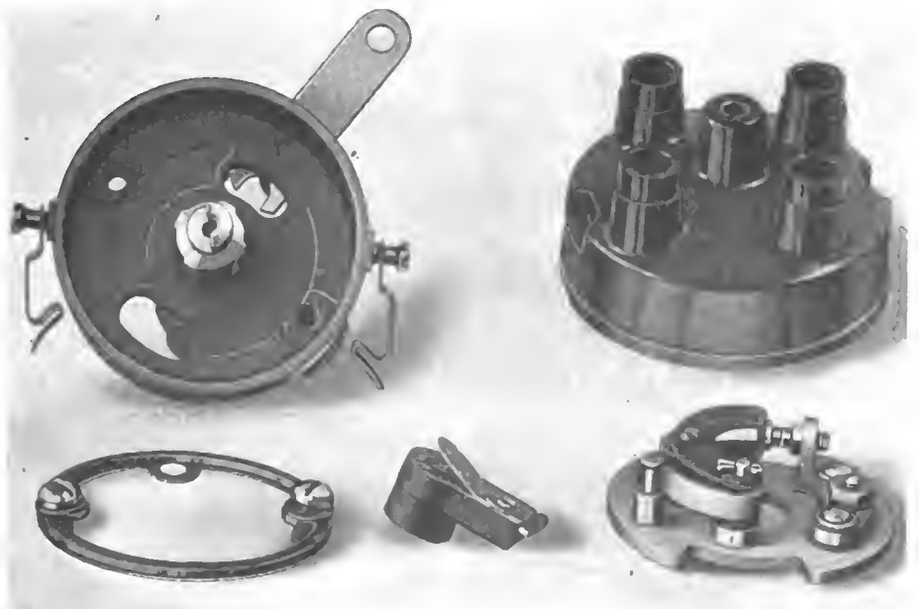


Details of the Bosch battery ignition breaker

The switch incorporates a vibrator attachment to facilitate starting; controlled by a button in the center of the switch plug. Under normal starting conditions momentary pressure on the button will produce a single spark at the plug. Turning the plug to the right and depressing it makes the necessary connection to provide a continuous stream of sparks at the plug and the button can be locked in this position until the engine has started.

There is only one adjustment, for the gap at the contacts. With the fiber block resting on the top of the cam the contacts should be separated about 0.01 in.

This Bosch battery system has been on the market a very long time, having been produced at a period when starting on the magneto was not as easy as it is now.

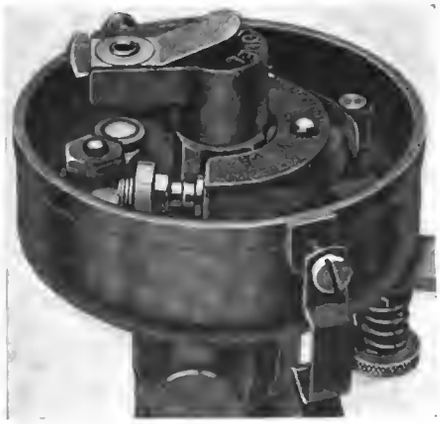


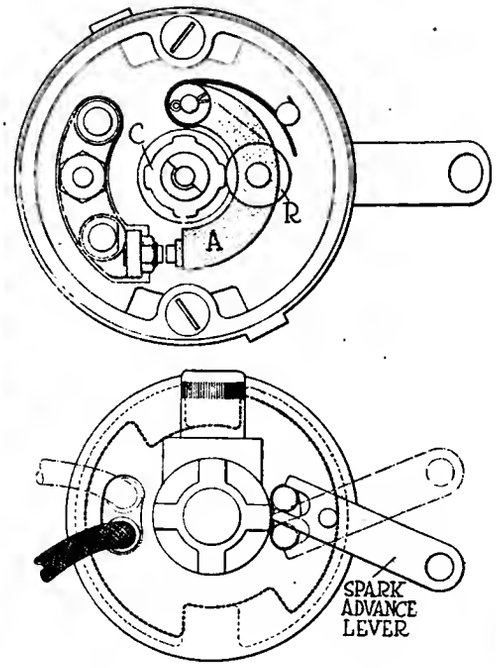
Connecticut breaker mechanism is mounted on a plate held by a spring ring under a solid ring. Removing two screws permits the breaker to be withdrawn complete

Connecticut Accessibility Improved

The closed circuit Connecticut instrument has not been changed in principle, the main alteration being in the advancing mechanism, which now is entirely internal and alters the relative positions of cam and breaker arm without moving the distributer or any of the wiring. The whole breaker as a complete unit can now be taken off for cleaning or adjustment more readily than before, as it is now retained by only two screws.

The new advancing device is particularly ingenious. The breaker is set upon a plate which can turn within the stationary outer case. In the bottom of the case is a small slot and through this a pin screwed into the breaker plate projects. On the bottom of the casing and outside of it, close to the slot, is a pin which forms the fulcrum for a short lever. The inner end of this lever is slotted and embraces the pin which comes





Left—The Connecticut complete assembly. Center—Removing the distributer head lays bare the breaker. Right—Diagrams of Connecticut breaker and of new advancing mechanism

through from the breaker plate, and the outer end of the lever is linked to the advancing rod.

The breaker carrying plate is held in place by a spring ring and a solid ring, the latter being held by the two screws mentioned.

The detail of the breaker mechanism remains unchanged. In operation, rotation of the cam C touches the fiber roller R in the arm A, thus separating the contacts and the arm is returned to its normal position by a spring.

The feature of the Connecticut system which eliminates the possibility of the battery being exhausted through the switch being left closed with the engine stopped is retained without change. This is effected by the use of a miniature thermostat which is in series in the primary circuit and which controls a mechanism similar to that in an electric door bell. If the engine is stopped with switch closed the primary current, in passing through the thermostat, heats it, thereby bending it and closing a circuit through the buzzer mechanism and this in turn automatically opens the switch. The action of the thermostat can be set for anything from 30 sec. to 4 min., the normal setting being about ¾ min.

There is a new type of high-tension lead connector using a brass ferrule. The wiring is stripped for about ¼ in. and the ferrule is slipped over and screwed into the insulation. Afterward a narrow portion of the ferrule is depressed, thereby locking it securely in place. The wiring fits snugly into tapered holes in the distributer cover, the assembly being completely waterproof.

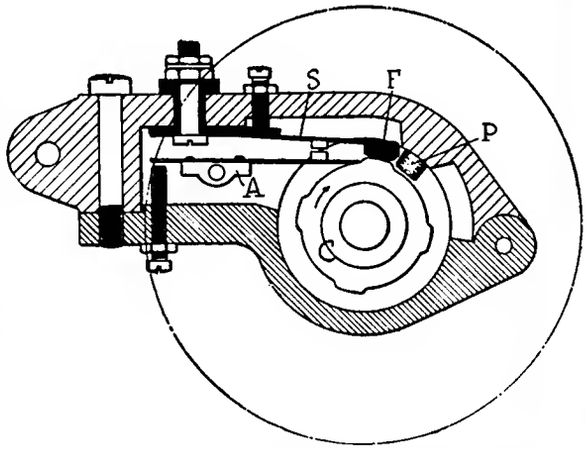
Another new feature is a simplification of the wiring to the coil, this now being so arranged, through the use of a hexagonal terminal, that it is impossible to put a wire on the wrong connection.

Philbrin Entirely New

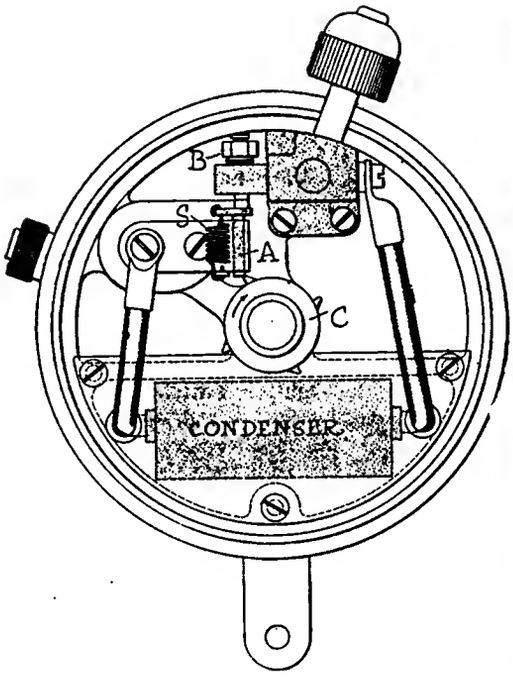
Described fully in THE AUTOMOBILE for Oct. 5, the Philbrin ignition is an entirely new dual system. Primarily it is a single spark ignition of the open circuit type, having a novel breaker mechanism. In addition there is, combined with the switch, a small vibrator which, when in use, sends a continuous stream of sparks to the distributer, providing a very effective ignition for a cold or poor gas. Either the single spark or the other ignition can be obtained by merely turning the switch.

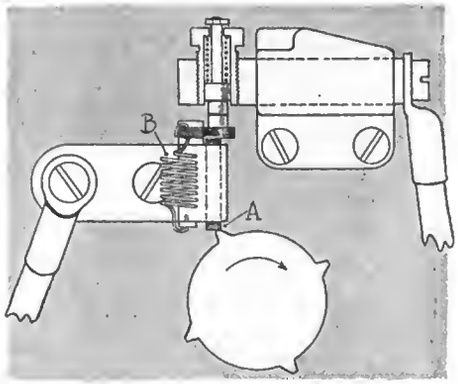
In the breaker there is what may best be called a plunger, carrying the contact at the outer end. The cam has a series of sharply pointed projections which hit the lower end of the plunger and lift it up against the fixed contact, the latter being backed by a small stiff spring. The contact remains closed long enough to saturate the coil, and the plunger is pulled back sharply as the cam passes on, by a coil spring. If the cam turns backwards the plunger gives way before it, being held in place by spring pressure, so the contacts do not close except when the cam is turning the right way. This breaker takes no part in the continuous spark, auxiliary system which sends its high-tension discharge to the distributer direct.

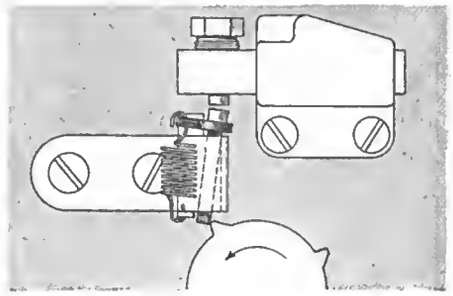
The distributer has a long arm with a blade of peculiar form which does not



Pittsfield ignition unit. The cam C first lifts blade A so closing the contacts, and then raises the fiber block F so lifting blade S and positively separating the contacts again. P is a wick for supplying oil to the cam





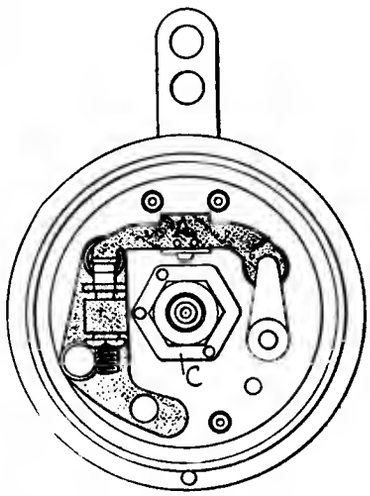


The Philbrin instrument and diagrams showing details of the breaker. The lower right hand view shows what happens when the cam revolves backwards, in which case the contacts are not brought together

touch the terminals molded into the Bakelite cover. It passes in very close proximity to the terminals and the spark passes a small air gap. The reason for the long blade is to insure a continuous stream of sparks at the plug during a considerable part of the piston travel. The current consumption under this continuous spark operation is about 1 amp.

The Philbrin switch also provides for two sources of current—the usual storage battery and an auxiliary set of dry cells. The arm is moved in one direction for the storage battery and the other way for the dry cells. The lever which controls the operation of the single spark or the continuous spark ignitions is a small, continuously rotatable plug. It is alternately marked M and S, designating whether the main or secondary systems are in operation. This switch also reverses the polarity of the current each time it is turned thus conserving the life of the contacts. The coil is contained in a metal case and is completely waterproof. It may be mounted on the dash and in some installations is mounted directly with the distributer mechanism. Two condensers are used, one for each system, and these are quite separate and both are amply protected.

There is but a single adjustment on the system this controlling the opening of the contacts on the main or single spark system. Naturally, improper running of the engine will suggest the advisability of dressing the contacts to smooth surfaces. The adjustment is plainly visible and the gap between the contacts should be 0.025—0.030 in. No adjustment is provided for the vibrator of the secondary, or continuous spark system, the manufacturers stating that it should never be touched.



Latest type of Remy ignition unit and diagram of the breaker. The arm A is a light steel stamping

Pittsfield Has Positive Action

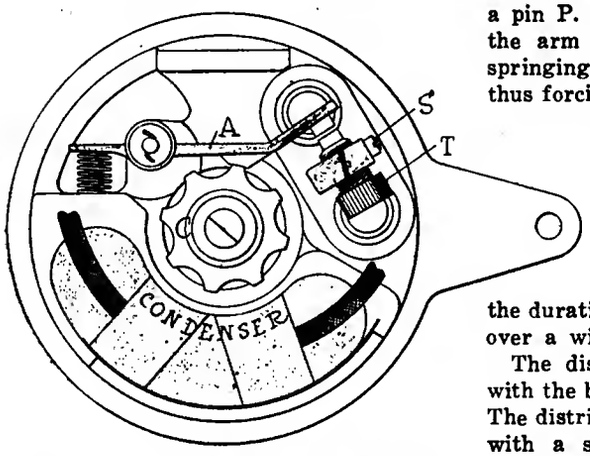
The Pittsfield open circuit system is unique in having the contacts both closed and separated by cam action, the timing not depending on a spring action. The contacts are mounted on two blades of stout spring steel, one having a steel and resting on the cam and the other a fiber block. Normally, with both spring blade ends on the flat part of the cam the contacts are held apart; then as the cam comes round, the shorter blade is lifted till the contacts close. Further movement causes the peak of the cam to pick up the fiber block on the longer blade, and this separates the contacts again. Since both these actions are mechanically performed by the cam there can be no lag due to hesitancy in spring action.

The contacts are permitted to remain together for the maximum length of time, thus assisting in the proper saturation of the primary winding of the coil.

The distributer and coil are in unit with the breaker and the cover is the usual Bakelite casing with the terminals molded in. The distributer arm does not touch the terminals, the spark jumping a small air gap. The coil is completely inclosed and is on top of the cover of which it forms a part.

It is exceptionally easy to disassemble the whole unit. The breaker mechanism is assembled in a sort of handcuff device which is simply clamped around the shaft. Removal of one screw permits the whole to be taken off for inspection. The only adjustment is for the opening of the contacts and this is easily accessible from outside the casing. Removal of the distributer cover and coil exposes the distributer mechanism and after the key

Above — Westinghouse unit comprising breaker, distributer and coil in one assembly. Below—Diagram of Westinghouse breaker. T is the point adjustment and S the locking screw



holding the camshaft has been withdrawn the whole shaft can be lifted out.

Remy Has Stationary Distributer

The breaker mechanism of the Remy battery ignition unit is very simple, and of magneto type, the cam bearing upon a fiber insert in the breaker arm. The circuit is normally closed and is broken only at the instant of ignition. In the sketch the fiber contact piece resting on the cam is designated by the letter F and it may be mentioned that the fiber is securely riveted to the breaker blade.

All the breaker parts are mounted on a plate which is rotatable within the fixed distributer head, the advancing lever coming out through the casing; there is no provision made for automatic advance.

The distributer mechanism has not been altered and consists of the usual Bakelite cover with the terminals molded in place. There is no wiping contact, the spark jumping from the radial distributer arm to the terminals.

The Remy coil has been altered slightly in the past year. The principle is the same, though certain refinements in the method of binding the high tension end of the winding have been made. On top of the coil there is a miniature resistance coil in series with the primary winding which protects this winding should the engine remain idle for any length of time with the switch closed. In short, it protects the winding and also prevents excessive drain on the battery.

Under ordinary conditions the contact points, which are iridium-platinum or tungsten, should not require attention more than twice a season. They should be adjusted so that the maximum opening is 0.020 to 0.025 in., or the thickness of the gage piece riveted to the wrench.

Rhoades Is Simplified

Sundry mechanical changes affecting the simplicity of the Rhoades open circuit igniter have been made during the year, but there has been no alteration in principle. In the sketch showing the latest type the cam C is loosely mounted on the shaft and rotated by contact with a pin P. As the cam rotates it presses the arm A outward and this arm, in springing back, hits against the lever L, thus forcing the contacts together for an instant. If the cam is rotated in the reverse direction it simply rides over the pin and does not bring the contacts together. The contacts are closed only by the momentum of the arm A so the duration of contact remains the same over a wide range of engine speed.

The distributer cover is conventional with the brass terminals molded in place. The distributer arm is keyed to the shaft with a set screw and cannot be improperly assembled, and the arm does not make contact with the terminals, the spark jumping a small air gap.

Westinghouse in One Unit

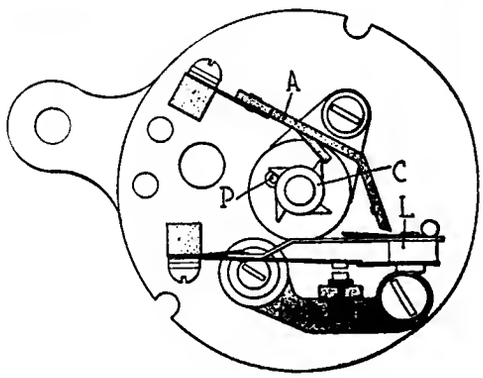
For its battery ignition the Westinghouse company uses the closed circuit principle, the breaker being about as simple as possible. It consists of a stamped steel arm with a contact at one end, and a fiber block about midway of its length, against which the cam strikes. At the other end of the arm there is a coil spring in compression, which keeps the contact points pressed together.

The whole unit is extremely compact, the condenser being mounted on the plate which carries the breaker, while the coil is contained in a chamber above the breaker, the distributer being at the top, above the coil. This means that the only external connection besides the high tension leads is the wire going to the switch.

The distributer arm, which is easily detachable, carries a double-ended carbon brush, the lower end thereof bearing on a ring of copper, and the upper making contact with the successive cylinder terminals. An opening in the casing can be uncovered for the purpose of trimming and adjusting contacts, while access to the distributer is obtained in the usual way. In adjusting the breaker the contacts should be dressed with a fine file and adjusted so that the maximum opening is 0.008 in.

The switch is combined in one mounting with the lighting switches, for attachment to the cowl board, and it is so constructed that the direction of the current is reversed each time the switch is turned. In the back of the switch plate there is what is termed a ballast coil. This is a small resistance in series with the final winding and is to protect the winding and prevent excessive drain on the battery should the motor remain idle with the switch in the "on" position. If this should be accidentally broken the ballast terminals may be temporarily short-circuited.

Rhodes open circuit timer-distributer with diagram of breaker below



Few Changes in Magnetos

Small Mechanical Details Refined But No Radical Alterations Made — Some New Models

PRACTICALLY the only changes which have taken place in magneto construction during the past year concern petty mechanical details. During 1915, when engine speeds were rising rapidly, several of the magneto makers modified their instruments to take care of the new condition. The work they did at that time, however, has proved so effective that there is no need for any further changes at the present time.

The condition affecting magneto manufacture which has changed for the better is the production of magnet steel in America. The bulk of this steel used to be imported and, when imports were cut off, most of the magneto makers had some trouble to discover a sufficiently reliable source of supply in this country. The steel makers, however, have done their best, with the result that satisfactory American magnet steel is now obtainable.

Whatever may be the ultimate outcome of the battery-vs.-magneto argument applied to passenger cars, it should not be imagined that the present predominance of battery systems in this field has caused a reduction in magneto outputs. The truck industry is using magneto ignition almost exclusively and cutting off the German supply has created a big export business, England and France both taking quantities of machines.

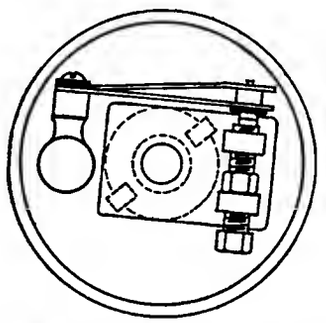
The immediate problem before the ignition industry in general, and the magneto part of it in particular, is the production of a satisfactory ignition device for aviation engines. The uninitiated would not anticipate any special difficulty in this connection. It would seem that a magneto that would operate for years in an automobile ought to be equally perfect for an aeroplane engine.

It has proved, however, that the continuous running at high speed, coupled with extra vibration, calls for a larger factor of safety both electrically and mechanically, while there is also, of course, a strong demand for a reduction in weight, despite the fact that the easy way to counteract the adverse conditions would be to make the machine larger and heavier. The problem is being met and several of the magneto manufacturers think that they have already solved it. Probably in another 12 months it will no longer be a problem.

There are two principles of magneto design; one has the coil wound upon the armature and the other has no wires on the armature whatever. The former type was evolved from the ordinary dynamo with, of course, permanent magnets. Some of the first machines had only a low tension winding in the armature and took the current from this through a separate coil which had both a primary and secondary winding. In other words, the current from the armature was merely substituted for current from the battery, the remainder of the system being identical for both sources of supply. A natural development was to eliminate the coil by placing the secondary winding directly on the armature.

In the Bosch type of circuit breaker a bell crank carrying the moving contact point turns with the armature shaft, the cam being on the inside of the breaker box

In the Dixie breaker a bell crank is used in conjunction with a cam which is fitted to the armature shaft



The Eisemann contact breaker consists of two springs separated by a fiber distance piece. The spring member nearest the center carries the movable, rotating contact point

The other system is entirely different. In it there is a small coil with high and low tension winding and this has a soft iron core. The core is so arranged that it forms a circuit passing from the north pole of the magnet through the core to the south pole and back to the north pole again through the armature. The armature is then so constructed that when in one position its iron part completes the magnetic circuit and when the armature is at right angles to this position the magnetic circuit is broken, since the armature then offers to the poles of the magnet surfaces of some non-magnetic metal such as brass or aluminum, or perhaps an air space.

Properly to appreciate the exact differences between the two types a considerable knowledge of electricity is essential, but a point in favor of the second system mentioned which is easy to appreciate is the mechanical simplicity of an armature with no wires on it. In other words, the wound armature type is not so easy to make.

No Changes in Bosch

In common with most concerns in the automobile industry, the Bosch Magneto Co. has been troubled considerably in the past year by shortage of raw material. In consequence of this the company has not considered the development of any new models, having devoted all its energies to an endeavor to maintain production of the existing types. It has been giving close attention to the requirements of the United States government for aviation engines.

There have been no changes in the Bosch system or in the mechanical detail for a good many years. Bosch was among the first to perfect the high-tension magneto with both the windings on the armature and also to develop successfully a system whereby a battery could be used in conjunction with the distributer of the magneto for starting purposes. In the days of large cylinders it was usual with battery ignition and vibrator coils to start the engine by merely switching on, as it would nearly always stop with a compressed charge in one cylinder. In order to provide a similar facility without the complication of a supplementary complete battery system, the Bosch company developed a small coil and vibrator which was combined with

Latest Dixie six cylinder

the switch and either a small storage battery or a dry battery. In these days of self starters the original need for the duplex system disappeared but it will give, of course, a strong spark at very low speed or will assist starting in cold weather or with poor grades of fuel. There is a very long list of Bosch models and the tendency in recent years has been to increase the production of the waterproof types.

Dixie Has No Armature

The principal exponent of the type with a wireless armature is the Dixie magneto, made by the Splitdorf Electric Co. This machine is unique in having the magnets placed the reverse way to the usual: at right angles instead of parallel to the rotative axis. Further, there is no real armature, but the poles of the magnets rotate. The pole pieces, as shown in the sketch above, are one-sided, so to speak, and the two are connected by a non-magnetic section. Each pole piece will have the same magnetization as the extremity of the horseshoe immediately behind it. Thus, we have two pieces of iron, one with north magnetism and the other with south magnetism revolving in a circle. Mounted in the horseshoe is a coil with a soft iron core and this coil has a "leg" at each end of laminated soft iron extending downward and embracing the rotating pole pieces. Thus, referring to the sketch, in considering one leg, it is easy to see that first the north pole is switched past it and then the south pole immediately afterward. This change causes alternations in the direction of magnetism through the core of the coil and this, in conjunction with the breaker action, sends current through the windings.

An ingenious feature of the Dixie instrument is the method of obtaining spark advance. Maximum efficiency is obtainable from a magneto if the break occurs when the pole pieces and the armature are in one particular relative position. In the case of the Dixie the break should occur always when the rotating pole pieces have reached just one position relative to the legs of the coil

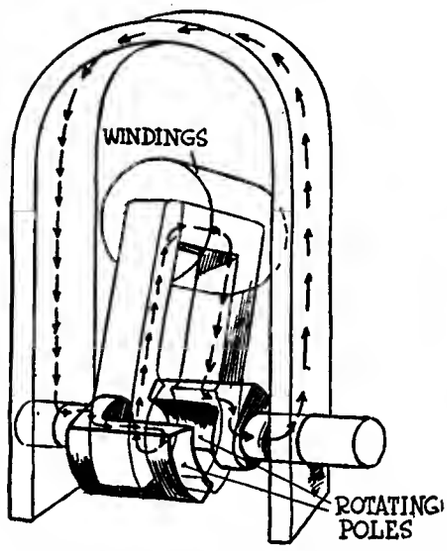


Diagram showing the path of the magnetic flux in the Dixie magneto. The windings are carried on a rocking field of laminated iron through which the magnetic lines are reversed twice in a revolution by means of the rotating poles which extend from the main magnet

core. To insure this movement the spark lever rotates the whole coil unit core, legs and all, exactly the same amount as it rotates the outside portion of the breaker. Thus the magnetic conditions are kept the same. It is possible to adjust the breaker of the Dixie while the machine is running, since the rotating portion is only a cam, the contacts, etc., being stationary.

There have been no changes in Dixie construction except a few small mechanical ones, mainly in connection with the detail of the breaker. The most important of these is a new way of arranging lubricating channels which allows just sufficient oiling to be supplied for the lubrication of the cam but prevents the accumulation of an excess. If a magneto is smothered with oil from the engine it merely drains off through an overflow channel. A slight increase in the range of advance is given on the four- and six-cylinder machines, this being changed from 30 deg. to 40 deg. and the distributer on the four-cylinder magneto has now only one carbon brush and resembles the distributer used on the six-cylinder. The present Dixie output of all types from four- to twelve-cylinder is about 1000 machines a day.

Strong at Low Speed

Unique in construction the Berkshire is another machine working on a somewhat similar principle is the Berkshire magneto, which was a new model during the year and was fully described in THE AUTOMOBILE for July 20, 1916. In this machine the magnets are arranged in the usual way and there is a rotating armature formed partly of iron and partly of aluminum. Referring to the section below, the two main poles of the magnets are A and B, while C and D are iron laminations running parallel with the armature, as shown in the other view. The iron parts of the armature are shown in black and when it is in the position shown the magnetic circuit flows from A to C through a segment in the armature, from C to D through an external circuit and from D to B through the other segment of the armature. Between the outer ends of C and D, joining them together, is a soft iron core upon which the coil is wound. Now when the armature turns so that the iron parts come opposite the poles, instead of bridging the gap between them as sketched, there is no complete magnetic circuit through the core of the coil. This means that revolving the armature continually makes and breaks the *magnetic* circuit, thus causing variations in the magnetic condition of the core of the coil. On the end of the armature shaft there is an electric current breaker of simple construction which is advanced and retarded in the usual way. A particular claim made for this machine is that it will produce efficient spark at as low a speed as 50 r.p.m., while the spark intensity does not become great enough to burn the spark plug points at high speed because the maximum spark occurs at a moderate speed. This is because it is impossible to magnetize the core of the coil beyond a certain degree, and this degree is soon attained. One of the Berkshire machines is made to deliver four sparks per revolution and this on a four-cylinder engine only needs to

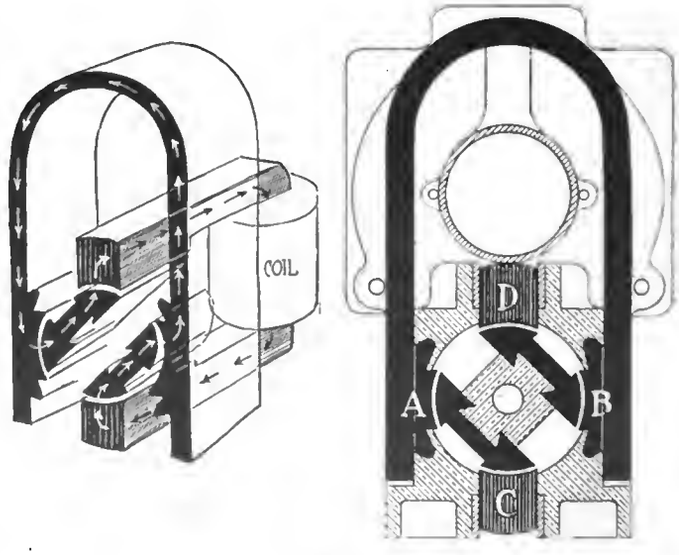

Diagram of Berkshire magneto system

run at half crankshaft speed. The four-spark type is made on six-cylinder engines to run at three-quarter speed and these two machines are applicable to eights, and twelves, by an alteration in the gearing and, of course, the distributer head. Two-spark machines are also made which will operate at the same gearing as that for most other magnetos. In the Berkshire magnetos the distributers have no carbon brushes, the high tension current being taken through brass segments projecting from a revolving cylinder of Bakelite. The outer part of the distributer is furnished with brass pins set so that there is a very small air gap between them and the segment.

Eisemann Has New Model

The Eisemann Magneto Co. is responsible for one of the very few entirely new magnetos, having added a machine which will be on the market early in January, and will be known as the G S. This is really very much the same as the G 4 in both external appearance and in principle. The mechanical detail has been changed considerably. The most important innovation is the use of a large die casting of an aluminum alloy in which the pole pieces are embedded. This single casting forms the end plates, carries the bearings of the armature and the distributer shaft, replacing eight large separate pieces and eliminating the need for a number of screws. This saving, coupled with the fact that the casting comes from the dies almost completely finished, effects a great economy in the cost of production. Therefore, the price of this new machine will be lower than that of the other Eisemann models.

Another new feature is the use of a compressed cloth gear for the distributer, this being used for the sake of quietness. The G S is a waterproof machine and has an extremely neat exterior.

For some years the Eisemann company has been making an impulse starter. This is a device which produces sparks at low speed without the addition of a battery. It may be described briefly by saying that a spring is interposed between the driving pinion in the engine and the armature shaft. When the engine is first turned over a catch holds the armature until movement of the starting crank has compressed the spring fully. As soon as this has occurred the catch is released automatically, causing the armature to fly forward very quickly. This is timed to take place just at the breaking of the contacts and a strong spark is thereby produced. As soon as the engine fires and starts to run a centrifugal device withdraws the catch and the magneto operates exactly as though the impulse starter was not there.

The company states that there has been a strong demand for this machine in the tractor field, and it expects to do a large business with the tractor manufacturers in the future.

Another Eisemann feature, which has been very successful, is an automatic spark control which is fitted to the armature of some of the machines. This is a centrifugal governor which operates a sleeve with a spiral groove cut in it which is interposed between the main portion of the armature and its shaft. As the engine speeds up the armature is therefore advanced relative to the driving gear, the breaker mechanism and the distributer, of course, being advanced a similar amount.

Remy Uses Separate Coil

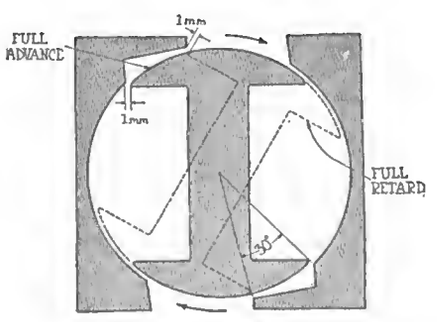
Remy magnetos have not been changed in any way this year and will retain all their present features. The Remy armature carries only one winding, this being a low tension coil of exceptionally large size. The distributer is mounted on the end plate of the machine in the usual way, the coil and condenser unit being entirely separate. The switch is built integrally with the coil so that the latter lies immediately back of the cowlboard, and all Remy machines are arranged to furnish dual ignition, the switch having a position which allows battery current to flow through the windings of the coil and of the armature. In this way the battery current supplements that produced by the armature and insures a satisfactory spark for starting.

A very useful feature of the Remy machines is the device known as the timing button. This automatically locates the armature and distributer in the firing position of No. 1 cylinder. To use this the magneto is disconnected from the engine and the crankshaft is set so that the piston in No. 1 cylinder is at the top of the stroke. The timing button is then pressed and the armature turned by hand until the button is felt to catch. The magneto is then in the correct position and if coupled to the engine without further movement the ignition will be set correctly.

Simms Has Four Models

Developed by some of the same individuals who designed the original Bosch machines, the Simms Magneto Co., with factories in America and Great Britain, originally built a magneto practically identical in system with the Bosch. In the course of years of manufacturing, mechanical differences have developed so that the Simms and Bosch machines of to-day have very little similarity. At present only four machines are being produced, two for four and two for six-cylinder engines, one furnishing single ignition and the other dual. The single ignition types can be converted to the dual by changing the breaker box and a few other parts.

A special feature of the Simms machine is the design of the pole pieces which have extensions on the edges following the direction of rotation of the armature. These extended edges keep the edges of the armature shuttle within influence of the pole in all positions from full advance to full retard. That is to say, that at the moment of breaking the current the edge of the shuttle is never widely separated from the edge of the pole piece. The possession of one very large contract has heretofore made it difficult for the company to accept much other business, but it is expected that the manufacturing facilities will be much enlarged within a few months.



Special pole piece used on Simms magneto to give equal spark intensity at all speeds

New Eisemann type G S magneto

Die casting used in Eisemann magneto The pole pieces are cast in place and hardly any machining has to be done on this whole piece, which replaces nearly twenty small parts used in the older designs

Spark Type Affects Power

Scientific Tests Show Character of Mixture in Cylinder Affects Quality of Spark Required to Insure Quick Ignition —Successive Sparks May Ignite Where a Single One Fails

By J. D. Morgan

THE following article from *Engineering* (London) although of an extremely academic kind, is none the less very interesting to all who have followed the spark controversy which has been raging more or less ever since the first days of electric ignition. The author is an independent investigator, and a member of several scientific societies, so his opinions are worthy of the most respectful consideration.

Two Contradictory Opinions

"There are current among engineers two opposed beliefs regarding the effects of spark intensity on ignition in internal combustion engines. According to the one, provided a spark is sufficiently strong to produce ignition, an increase of strength has no effect on either the rate of combustion or the maximum pressure attained; consequently such increase has no effect upon the power developed by the engine. According to the other the strength of the spark does have an effect upon the power, and it is therefore assumed that the spark strength influences both the rate of combustion and the maximum pressure attained. Obviously both assertions cannot be true, yet it is possible that the one which is untrue has some foundation in fact, and has arisen out of a misinterpretation of experimental results.

"Regarding the terms 'strength' or 'intensity' as applied to sparks for ignition purposes, no clear meaning is or can be attached to them. The terms are unsuitable because as ordinarily used they refer to the total heat energy of a spark, and this alone does not determine the ability of a spark to ignite a given gas mixture. To meet the difficulty the term 'incendivity' has been proposed by the writer* to denote the property whereby a spark produces ignition of a combustible gas. The term is convenient for descriptive purposes, but no quantitative definition can yet be given. In the absence of a standard of incendivity sparks are ordinarily compared by measurements of their heat contents, except in special cases where they are referred to the energy supplied to the circuit which produces the sparks.

Tests in Special Vessel

"The principal investigations on the subject of spark ignition in internal combustion engines have hitherto been carried out by means of engine tests, the effects of different sparks being observed either on explosion diagrams or brake measurements. For the purpose of the investigation here recorded it was decided to explode in a chamber of constant volume weak, quiescent gas mixtures at normal temperature and pressure, for the reason that the main facts can be more easily and definitely determined in this way than in engine tests, where the variable factors of the problem are less easily controlled. The sparking was in all cases at one position, this being approximately at the center of the explosion chamber.

"In carrying out the experiments a mixture was found by trial which produced explosions of moderate rapidity, as the indicator diagrams of such explosions can be more easily and accurately compared than those obtained by very rapid or very slow explosions. Using throughout a coal gas mixture of the same composition, sparks from the following sources were employed:—

(*a*) High-tension magneto.

(*b*) Induction coil with cam-operated make-and-break (primary supplied by 12-volt circuit).

(*c*) Induction coil with vibratory make-and-break (primary supplied by 4-volt circuit); 200 vibrations per second.

(*d*) Lodge condenser apparatus, vibratory make-and-break (primary supplied by 8-volt circuit); 70 vibrations per second.

"The above are the principal types of apparatus used in practice. The heat contents of the sparks measured by means of the author's thermal balance were as follows:—

(*a*) 0.01 joules per spark at 120 r.p.m.
0.03 joules per spark at 1000 r.p.m.

(*b*) 0.02 joules per spark at 80 r.p.m.
0.0018 joules per spark at 1000 r.p.m.

(*c*) 0.0005 joules per spark.

(*d*) 0.026 joules per spark.

"In all cases the diagrams were identical, both as regards the rate of combustion and the maximum pressure. From this it is evident that provided a spark is capable of producing ignition, increase of incendivity has no effect upon the power developed in the engine. This result confirms what has previously been ascertained from engine tests. The fact has not yet, however, met with general acceptance among engineers.

What Is Spark Strength?

"Having regard to the foregoing, the question arises: What ground is there for the belief that engine power is affected by the incendivity or so-called strength of the igniting spark? The experience is common among users of internal combustion engines that an increased spark sometimes results in improved operation of an engine, particularly when weak explosive mixtures are employed. The answer is to be found in the fact that an explosive gas mixture requires for its ignition a spark having not less than a certain incendivity, and the latter varies with the nature and proportions of the mixture. When the proportions of the mixture are at or near the upper or lower limits beyond which ignition is impossible the required incendivity is high. But as the proportions approach that of maximum explosibility the required incendivity rapidly diminishes. Hence for a given gas mixture a certain minimum incendivity is necessary in the spark. If the incendivity is near the limit a diminution in the explosibility of the mixture may result in no ignition, or only intermittent ignition. This can be rectified by employing a spark of higher incendivity, providing a greater margin for gas variations. In a gasoline engine, particularly when running at slow speed, weak mixtures requiring strong sparks for their ignition are often obtained, and when the ignition system is insufficient to provide suitable sparks defective operation of the engine ensues. On replacing the ignition system by another producing stronger sparks the engine works satisfactorily. Arguing from this, the user concludes that the better spark has

* "Notes on the Ignition of Explosive Gas Mixtures by Electric Sparks." Vol. 54, No. 254, Journal of the British Institution of Electrical Engineers.

increased the power of his engine by increasing the rate of ignition or the maximum pressure, whereas actually it has only eliminated misfires.

"From the practical standpoint the facts relating to 'single point' spark ignition in internal combustion engines are comprised by the statements (1) that provided a given spark is sufficient to produce ignition any increase of incendivity does not affect the power obtainable from the explosion, and (2) that as the mixture passes from the proportion of maximum explosibility toward the higher and lower limits the required incendivity of the spark increases.

No Theory of Ignition

"An outstanding and as yet unsolved problem in connection with ignition apparatus for internal combustion engines is that of defining the least sparks required to produce ignition of a specified gas mixture, and with this problem is associated in general that of spark measurement. In the absence of an established theory of ignition any attempt to define a spark must necessarily be tentative, but some satisfactory temporary expedient is not impossible. Obviously the procedure of defining a spark in terms of the current in some part of the apparatus used for producing the spark is highly unsatisfactory, because sparks defined in this way are not comparable when produced by different apparatus. Any satisfactory method of spark measurement must involve nothing more than the spark. The most obvious and up to the present best developed method is the thermal one. In this it is usual to heat a quantity of gas by a succession of sparks until a steady state is reached, that is, the heat imparted to the gas is equal to the heat lost by the container. The average heating effect of the sparks can then be calculated and the heat content expressed in joules per spark. At first sight it would appear that the incendivity of a spark could be expressed as a function of the heat-content, and if this were possible sparks could for practical purposes be defined in terms of joules per spark. There are, however, two facts which limit the usefulness of the thermal method. The first is that incendivity does not depend upon heat alone, but apparently on heat jointly with temperature, and the other that ignition seems to be the result of a cumulative action which can be set up by a succession of sparks when a single spark fails.

Temperature Important

"It is a matter of simple experimental proof that heat alone does not determine the incendivity of a spark. Using the same source of energy, say a magneto, two different types of sparks can be obtained, one by using the magneto normally and the other by connecting a condenser across the spark gap. The latter is contained in an explosion chamber which is filled with a weak gas mixture, and the magneto is adjusted so that working normally it produces a spark which will not ignite the gas. A condenser of suitable capacity is then attached across the gap, and by means of the resulting spark the gas may be exploded immediately. On measuring the thermal contents of the sparks it is found that the heat contained in the normal magneto spark is not less than that obtained with the condenser, and if a poor condenser is used it may be as much as 100 per cent more, as in one set of experiments carried out by the author. Yet the spark containing more heat failed to produce ignition where the other succeeded. The only apparent difference was the temperature. It might be suggested also that the duration was different, and the shorter duration of the condenser spark caused it to be accompanied by greater mechanical violence. But for this there is no experimental evidence. Both sparks are oscillatory, and the effective portion has apparently the same duration in both cases. It follows, therefore, that incendivity is not a function of heat only, but of heat and temperature. And as the heat-measuring instrument accounts only for total heat, the measurement of joules per spark is only useful for comparing sparks produced by similar apparatus.

"The second fact, that ignition appears to be the result of a cumulative action, is of less practical importance in connection with ignition apparatus for internal combustion engines, seeing that single sparks are now more generally used. But for purely theoretical work the fact is of importance. Using a magneto provided with a variable resistance in its primary circuit to permit large variations of the spark in the secondary circuit, and employing a needle point spark gap, very small sparks can be obtained. Keeping the gas mixture constant and varying only the speed or the primary current of the machine, it was found possible to arrange a condition in which the gas would never ignite with the first spark, and only after a number of sparks had been passed through could ignition be produced. Owing to the extreme difficulty of insuring perfect uniformity of conditions (a trouble which is common in work of this kind), the results were not sufficiently regular to permit of a quantitative deduction, but the persistence of the phenomenon was such at all times that only one conclusion was possible, namely, that succeeding sparks produced a progressive change in the gas which finally resulted in ignition, in other words, the ignition was the result of a cumulative action. The pre-ignition period could be shortened by increasing the strength of the spark (viz., by increasing the speed or the primary current), or by adding a condenser across the spark gap. The largest pre-ignition period noticed was about 2 seconds with the magneto running at 5 r.p.m. In a previous investigation* using low tension sparks the author observed a similar effect. The results obtained with the less active sparks were more regular and the pre-ignition interval was longer. Having regard to the foregoing, the difficulty of defining the least igniting spark for a given gas is apparent, but, as previously stated, where under practical conditions only one spark (or a plurality of simultaneous sparks) is used for igniting an explosive charge the difficulty disappears.

Condenser Effect Important

"The trend of scientific opinion concerning spark ignition is that the action is ionic. It is not suggested that the heat of the spark is unrelated to the process of ignition, but that the thermal and ionic conditions are intimately connected. A natural alternative, if not a substitute, for a thermal instrument for measuring incendivity is the electroscope. The application of the latter for this purpose is not easy, because a number of arbitrary conditions, such as the shape and position of the spark gap relatively to the charged surfaces, and also the magnitude of the charge itself, have apparently to be stipulated before measurements can be usefully compared. Nevertheless the electroscope appears to contain useful possibilities in this connection. It is a matter of simple experimental verification that the sparks of a condenser produce a larger discharge per spark than do sparks obtained when the condenser is removed, although the heat content of the latter may be the same or even greater than that of the former."

Goodyear Cord Tires Easy to Repair

WHEN a Goodyear cord tire has ben damaged it is not necessary for the automobilist to send the tire to the factory for repair, according to L. C. Rockhill, manager of the automobile tire department of the Goodyear Tire & Rubber Co., Akron, Ohio. Any tire repairman can repair one of these cord tires just as he would a fabric tire, using regular fabric, without impairing the efficiency of the casing. For this work no special machine is necessary. In the Goodyear construction six to ten layers of strong cords are used, the number of layers depending upon the size of the tire. The method of applying these cords gives rise to the name of the thread system by which it is widely known. The cords are held in place by a few very fine threads which break when the tire is used, leaving only the cords.

Correctly Figuring Valve Capacity

By E. H. Delling

IN reference to the article entitled Valve Sizes Need Definition on page 703 of THE AUTOMOBILE for Oct. 26, may I be permitted to criticize the suggestion that the area of the clear valve diameter minus the area of the stem should be given as a basis of comparison?

I am of the opinion that it is altogether wrong to consider the area of the valve port as an indication of the "valve capacity," if I may call it so. An example will illustrate my point very clearly. The full-size sketch, Fig. 1, shows the actual dimensions of a valve of the 22-70-hp. Mercer engine.

Employing these few figures we would have a clear valve area of $\frac{2.25^2 . \pi}{4} = 3.97$ sq. in. Subtracting the area of the valve stem, which is 0.110 sq. in., leaves 3.866 sq. in. as the value which your article proposes. Now let us see what actually offers the greatest restriction to the incoming charge. Considering the valve in the extreme, lifted position, the gas will follow the contour of the seat and escape through a slot the length of which is the clear diameter of the valve multiplied with π and the width of which is a line connecting the small diameter of the valve with the largest diameter of the seat. We will call this width h_1. We then obtain the following expression if we call the effective maximum valve opening O_{max}:

$$O_{max} = (d + b)\pi . h_1$$

In our case we would have

$$O_{max} = (2.25 + 0.125)\pi . 0.328$$
$$= 2.45 \text{ sq. in.}$$

This is the actual opening, and comparing it with the port area minus the valve stem, we find that it is only 63.3 per cent of what the former article assumed as correct.

Still this absolute value of 2.45 sq. in. does not permit comparisons and I think we should go a step further. I have always made it a rule to express such values specifically, *i.e.*, per liter or cubic inch of piston displacement. As the Mercer engine has 298 cu. in. displacement, we would have 0.033 sq. in. available for each cubic inch of gas taken in, assuming that the volumetric efficiency is 100 per cent. This value allows a direct comparison of any size and lift of valve for any displacement. The above consideration is the prime reason for double inlet valves. I have never seen this reason stated clearly in any article on that subject. H. R. Ricardo, in a treatise on High-Speed Engines in *The Automobile Engineer* for August, 1916, page 225, states:

"Now the effective area of opening of a poppet valve is equal to the area of the port when the lift is equal to one quarter of the diameter (this is not strictly true but is very nearly so)."

This statement in itself is correct, but it is based on an assumption which is out of the scope of everyday practice. I cannot recall a modern stock engine with such a tremendous lift except the Vauxhall Prince Henry model which, however, can hardly be called a stock product and which represents a very small percentage at any rate. Most valve lifts range from 5-16 to ⅜, very seldom more. So why assume something which is not the average but the exception.

He then proceeds to replace one valve of 2.2 in. diameter by two of 1.55 in. diameter, the combined port area of which would equal that of the single valve. With a lift of current practice, say ⅜ in., we would obtain by above formula for the single valve an opening of $O_{single} = 2.43$ sq. in., for the double valves $O_{double} = 3.45$ sq. in. It will be observed that the gain is appreciable, 42 per cent to be exact.

Some designers may object to using the same lift for the large as well as the small valve. But there is no reason why a small valve should not be lifted as high as a large one, in fact it is much easier to accelerate the small mass of the light valve. I always regarded the lift a factor of the cam shape, spring tension and timing and not so much of the valve size.

Assuming an intake opening of 5 deg. after D. C., a closing of 45 deg. after D. C. and a tappet clearance of 0.005 in., we will have a valve period of 120 deg., or 60 deg. is the included angle formed by the cam flanks. If we assume a base circle of commercial practice, say 1¼ in. diameter, we shall find that lifts over ½-in. are practically impossible due to the fact that the cam shape approaches a point.

To sum up we can come to the conclusion that the valve capacity of an engine changes in direct proportion to the diameter of the intake valves multiplied with the number of valves *and not with the square of the diameter* as is often assumed. That means, 12 intake valves of 1½ diameter have a certain capacity, and whether they are arranged as single valves in a twelve cylinder or as double valves in a six cylinder, is secondary consideration. This assertion is backed up by the high speed of the Sunbeam six-cylinder racing car with double valves and of the Packard racing car with twelve-cylinder aviation engine, having single valves. Both cars have twelve intake valves available for the passage of the inrushing charge; therefore their high volumetric efficiency. Whether the gas is burnt in six or in twelve cylinders is immaterial from the standpoint of valve capacity.

A New Semi-Diesel Engine

By Edwin S. Strickland

AS an experimenter on two-cycle and semi-Diesel engines I have developed a type of construction which entirely overcomes such defects as: Hard starting; backfiring; fouling; waste of unused fuel; accumulation of carbon; condensation of mixture before explosion; and bad or uncontrollable regulation

The first four defects existent in two-cycle engines of the carbureter type are due to co-mingling of fresh and exhaust gas which does not occur with clean air as a scavenger in the semi-Diesel principle.

The last three defects existent in semi-Diesel engines are overcome by varying the quantity and temperature of air compressed, in proportion to the oil atomized against the com-

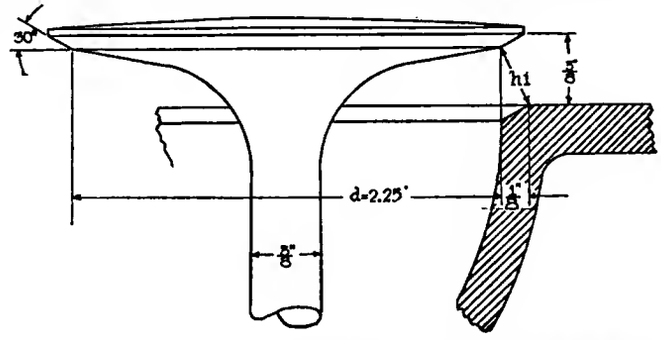

Fig. 1—Full-size sketch, showing actual dimensions of a valve of the 22-70 hp. Mercer engine

At the right are reproduced the two illustrations, Figs. 4 and 5, from an article on engine testing by W. Ferrier Brown in The Automobile Engineer, England, and reprinted in digested form in THE AUTOMOBILE *for Oct. 12. Fig. 4 gives four efficiency curves, viz., mechanical efficiency, brake thermal efficiency, indicated thermal efficiency and available efficiency (as compared with the air standard). Fig. 5 shows the relative values of the "air standard" and the "maximum available" efficiencies as a percentage of the total heat energy of the fuel consumed.*

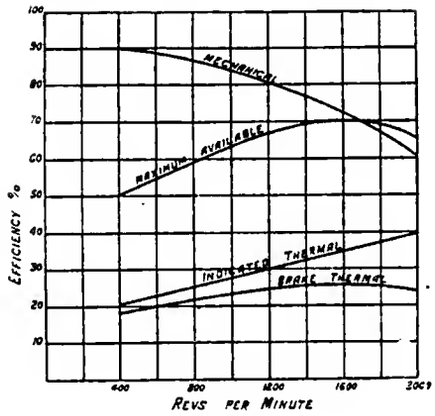

Fig. 4

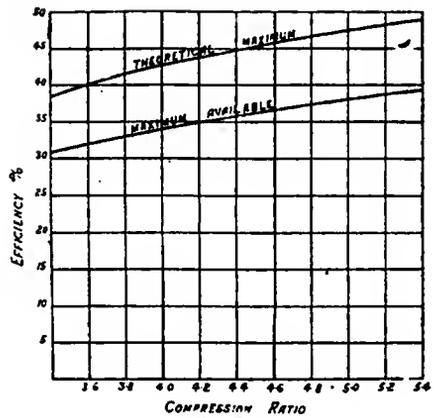

Fig. 5

bustion plate; no partial vacuum is formed in the cylinder.

Kerosene is used for fuel and will operate under idling conditions, while gasoline is used for starting purposes only.

Further improvements consist of a vacuum-breaking valve in the exhaust pipe to prevent drawing the scavenging air cut of the cylinder; a circulation of oil around the bearings, serving the double purpose of lubrication and of forming an oil-seal to prevent compression escaping from the crankcase; a bumped piston head is used to prevent sizing and also to protect the rings from the heat of the explosion; a small fly-ball regulator permits rapid advance of spark and compression by the operator without liability of stalling or reversing. The fly-ball regulator also varies the regulation of warm air to the intake pipe in order to maintain a normal temperature of air admission; and a water-cored exhaust port bridge prevents sizing of same against the piston, while an air passage of 45-deg. angle to the cylinder insures scavenging with no resistance to the air as in a right-angle passage deflector.

The above improvements in connection with the inherent advantages of 40 per cent reduction in parts and weight, cheaper fuel, less surface to lubricate, an explosion each revolution, with no valve in the combustion chamber, make this type of engine the ideal and ultimate motor.

Brake Thermal Efficiency Error

By R. W. A. Brewer

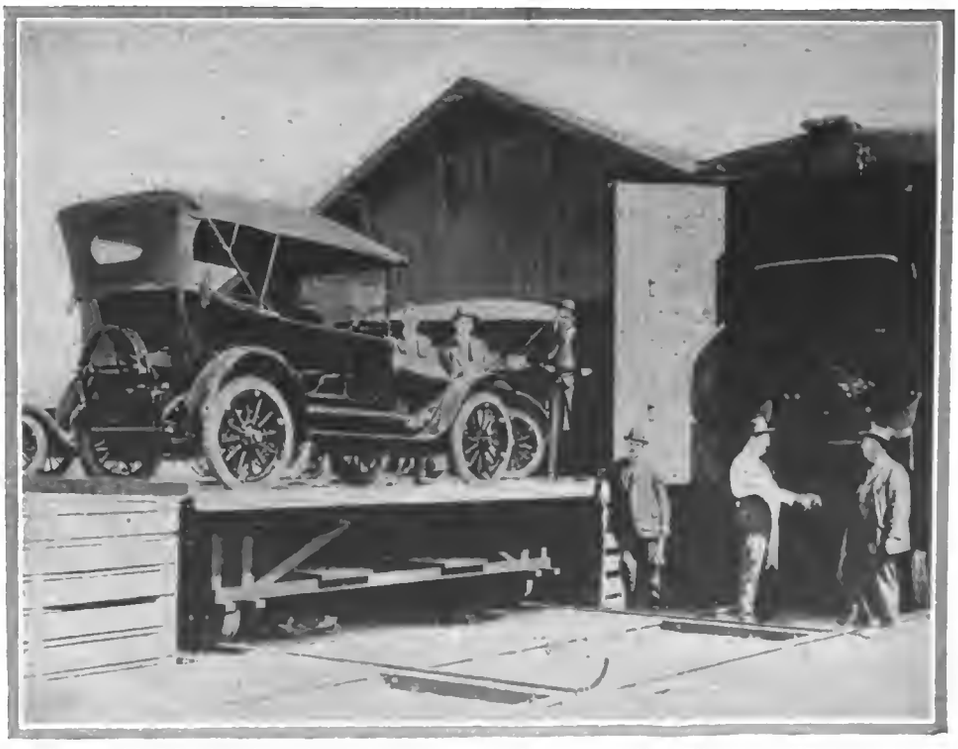
IN Mr. Clayden's abstract of W. F. Brown's article on testing engines, page 620 of THE AUTOMOBILE, Oct. 12, there is apparently an error in respect to the brake thermal efficiency.

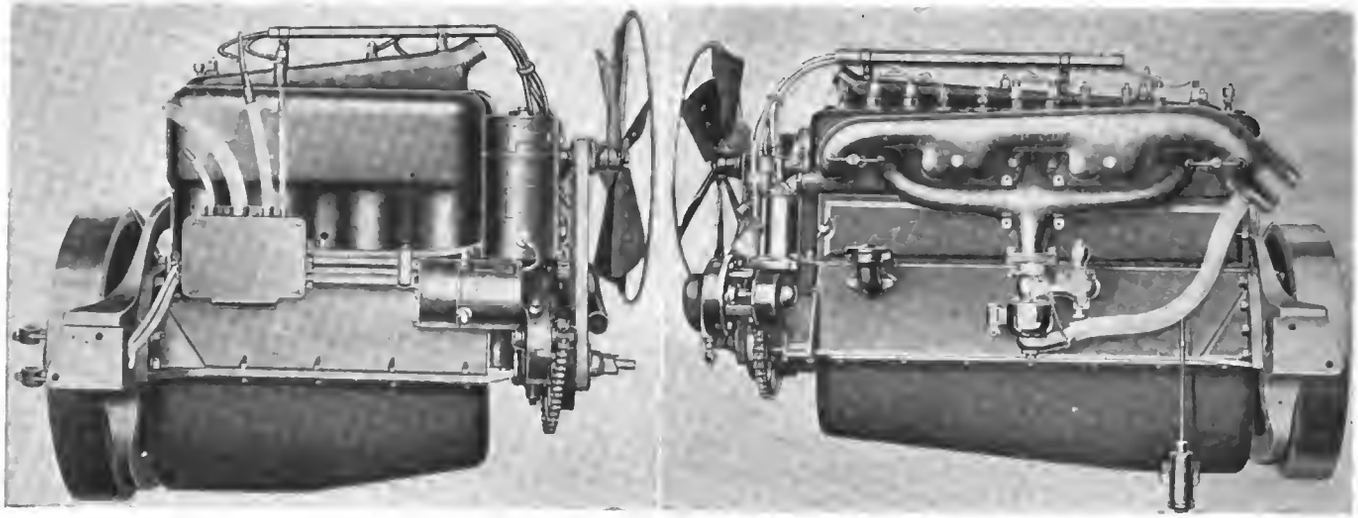
Direct Values Given

It is stated that Fig. 4 shows a "curve of the brake thermal efficiency taken as a percentage of the maximum available efficiency shown in Fig. 5." A study, however, of the curve in question would show that the values given are direct values and indicate the proportion of the total fuel which actually appears as work at the crankshaft of the engine, and this is of the order of 20 to 25 per cent of the total heat in the fuel. Going a step further, the curve in Fig. 4 shows 25 per cent as its best value and assuming the compression ratio of 4 to 1, the "maximum available" from Fig. 5 shows about 34 per cent, so that the ratio of the actual to the maximum available is about 73.5 per cent.

A Car Unloading Platform

AT the right is illustrated a unique device for saving time in unloading automobiles from freight cars. It is the invention of C. A. Dundas, Studebaker dealer in Riverside, Cal. It consists simply of a platform on a level with the height of the freight car floor, the platform being on wheels and moving over tracks. The automobile is rolled off the rear of the freight car and onto the movable platform, the illustration showing one car which has just been rolled on the platform and a second in readiness. The Santa Fé railroad officials thought so well of the scheme that they have made arrangements with Mr. Dundas, the inventor, to have the device installed. The unloading of automobiles at their destinations has long involved a waste of time, which is eliminated by this platform, the expense involved being small.





Left—Engine of the Studebaker four, illustrating junction box for wiring at rear, vertical generator mounting, and chain drive starting motor. Right—Carbureter side of engine shows the arrangement of manifolds on the Studebaker six

Studebaker Continues Four and Six

Redesigned Piston and Electrical System Chief Mechanical Changes—New Patent Auxiliary Seats

STUDEBAKER four- and six-cylinder cars are to be continued for 1917 with several minor changes. As far as the basic design is concerned, the cars are unaltered, but they are presented this year with better finish, better equipment, and better engine characteristics than last year, at a price increase of $130 on the six-cylinder touring car and $55 on the four. Both of these are seven-passenger cars selling respectively for $1,180 and $940.

From an exterior standpoint, the most striking alteration in the Studebaker cars is the use of a gunmetal finish. This is a twenty-five-operation job and the fender trim is in black, giving a distinctive appearance to the new model. Besides the change in finish, there have been a number of other body improvements designed to give more room and comfort to the passengers. The new auxiliary chairs have arms and are an exclusive Studebaker design. They are roomier than the previous auxiliary seats and instead of folding up behind the front seats or under the floor, they are carried beneath the back seat, thus when the auxiliary seats are out of sight, as far as appearance is concerned, this is a five-passenger car.

Another innovation is the use of a reversible front seat. With this the passenger seated beside the driver can sit facing the tonneau or facing forward as he desires. Both the front seats are covered with leather and are fitted with robe straps and are adjustable to all leg lengths.

Another comfort feature is the use of the Blackmore patented storm curtains which open and close with the doors, thus giving all the conveniences of an inclosed body when the side curtains are in place. For those who desire a permanent top in winter there is a new form of convertible which is made exclusively for the Studebaker product and which can be removed readily and the summer top substituted.

Along with the more comfortable body and the better finished exterior, the interior has been given a considerable amount of attention. There are now door pads on the doors. The upholstery is all in semi-glazed, straight-grained genuine leather with curled hair. The tonneau carpet is all wool and bound with leather. The top is silk mohair bound with leather edging, and in the way of interior equipment a new Yale switch lock of pin-tumbler type has been added to guard the car against theft.

New Studebaker auxiliary seats which fold beneath rear seats

Pistons 5 Ounces Lighter

Mechanically, the improvements are very slight and only of a detail nature. Probably the most important is a reduction of 12½ per cent in the weight of the pistons, making them 5 oz. lighter than in the 1916 cars. This reduction in weight has been accomplished by milling out the skirts.

The oil pump has been changed slightly in the way of making a tighter fitting pump which has increased its pumping ability. The rear axle has been stiffened and strengthened, giving a higher factor of safety in this part, and in the electrical equipment, improvements in the design have increased the cranking power by 12 per cent., this increase in the electric cranking effort being due to improved winding of the motor. The generator has also been improved by alterations in the wiring which give much better charging characteristics. About 3 amp. increased current is furnished the battery at a car speed of 15 m.p.h., while the maximum charging rate has not been altered. The practical result of this change as it concerns the driver is that the slow speed operator will get better charging performance and the battery will not be injured by the faster driver. Another detail change in the electrical equipment is in the headlamp mounting by means of which the lamp can be turned and fastened in any position.

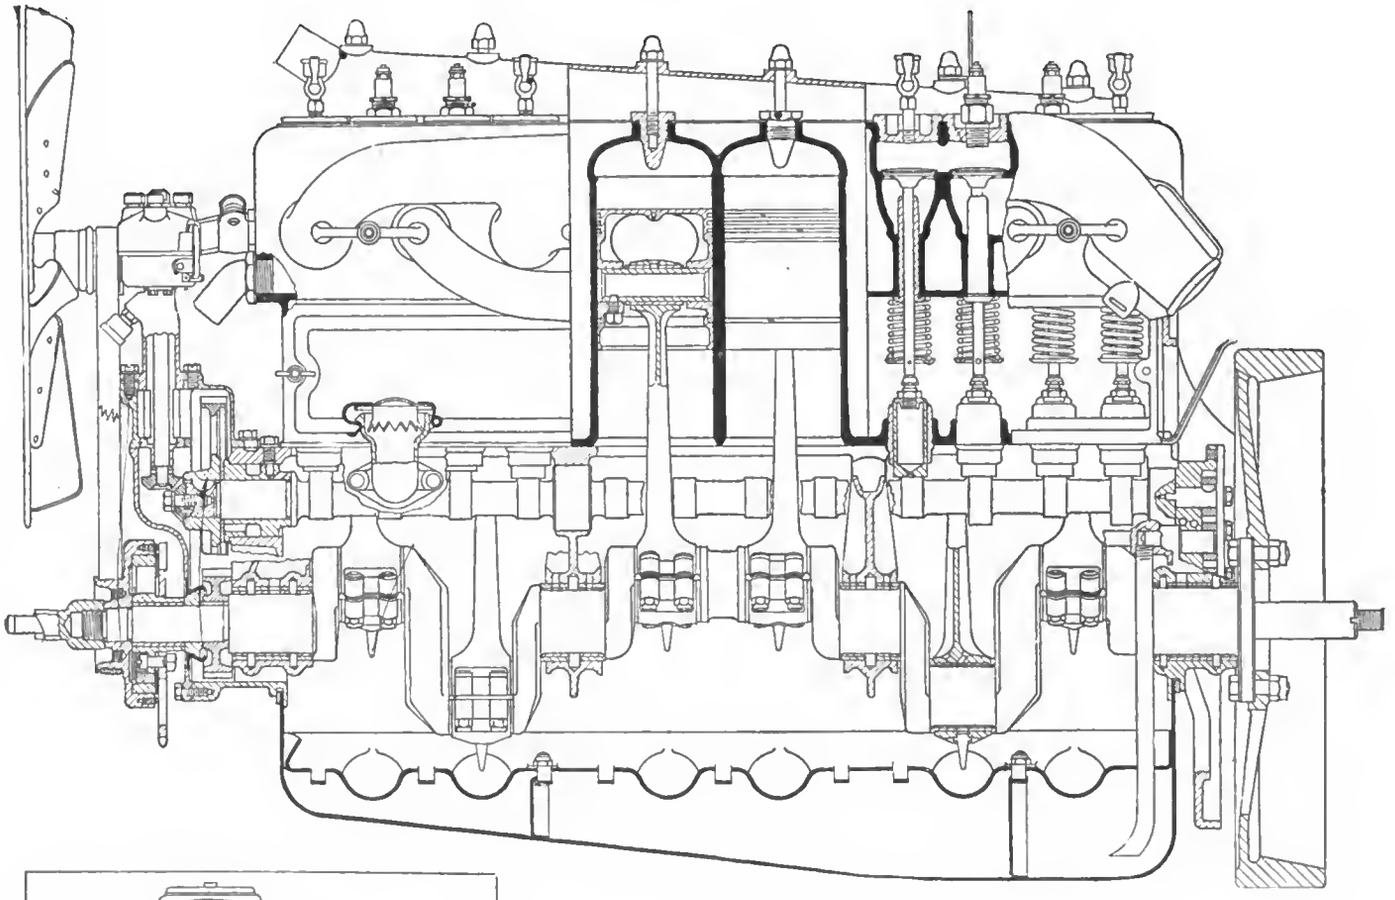
From a manufacturing standpoint, the outstanding feature of the Studebaker line is its standardization. The four and six are exactly similar in design throughout, both engines having their cylinders cast in a single block of similar dimensions, 3⅞ by 5 in., and with all parts similar from one end of the chassis to the other; excepting where structural dimensions differ on account of the difference in the power plants.

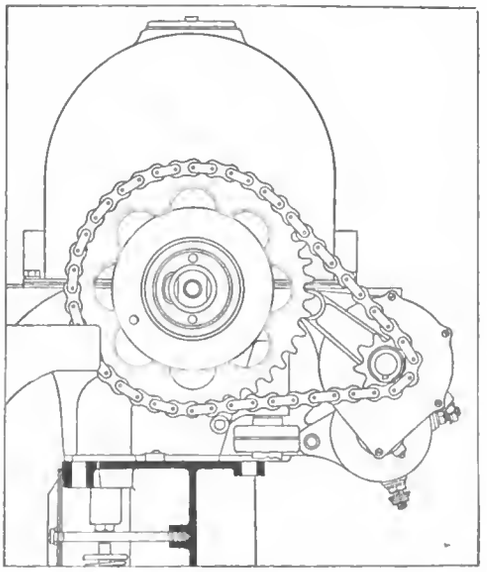
For 1916 Studebaker cars were redesigned and a considerable number of alterations were made in the power plants. For 1917, the engines which were introduced have been continued practically without a single change. The other Studebaker characteristics have also been continued this year and the rear axle gearset, cone clutch, and Wagner electric units are all found in the latest models. In the cars of 1916 the cowl gasoline tank was used for a time, but this was changed over so that on the 1917 models there is a vacuum feed from the rear tank.

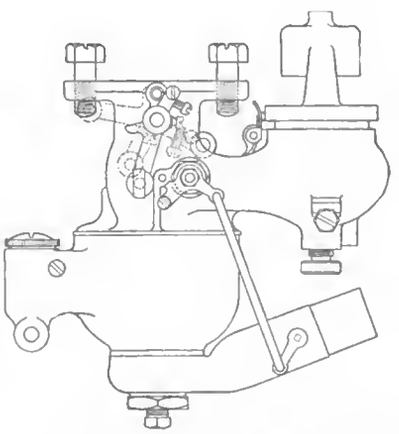
Both the intake and exhaust manifolds are on the left with the carbureter carried on a horizontal flange at the bottom of the intake header. A particular feature of the intake manifold is in the smoothness of the interior surface and the elimination of sharp bends. The hot air stove is attached to the exhaust manifold at the rear of the engine and is carried direct to the air intake of the carbureter by a flexible tube.

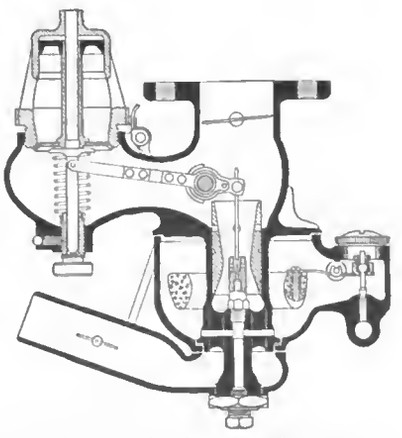
Connecting Rods Taper

Cylinders follow conventional design as illustrated in the sectional drawings, and a noteworthy feature of the connecting-rods is the taper from top to bottom in order to give a constant strength column between the wristpin and









The principal change in the Studebaker engine is reduction of reciprocating weight. Observe the large water spaces round the valves The small views show the roller chain drive for the starter and the carbureter with fuel and air adjustments

Upper—Studebaker six-cylinder, four passenger coupé. Lower —Landau roadster which makes a convenient car for physicians and professional men

the crank pin bearing. The center lines of the connecting-rods are slightly offset, as will be noted from the longitudinal section. In the six-cylinder engine the crankshaft is carried on four main bearings, and in the four there are three main bearings. The entire assembly of piston, rod and crankshaft is featured by high strength factors secured by liberal dimensions. The wristpin is secured in the piston boss by a set screw and the bearing bronze for the upper rod bearings secured in the upper end of the rod. At the lower end of the rod there are four alloy steel bolts provided with shims between the cap and bearing for adjustment.

No alteration has been made in the valve action. The camshaft is driven by helical gears directly from the crankshaft and the tappets are the same constant-diameter units adopted last year. These cylindrical pieces, being of the same diameter at the bottom as they are at the top, can be drawn from the crankcase by simply lifting the valve and the spring out of the way.

Lubrication is by a circulating splash system with a gear pump. The oil is driven from the crankcase reservoir through a lead running the entire length of the crank case with a duct to each of the main bearings. The oil is forced through this and the pressure under which it is being fed is registered upon a gage mounted on the dash. The oil passing through the entire length of the main lead flows to the timing gears and acts as their lubricant. The overflow from the main bearings enters the splash troughs where it is picked up by the scoops at the bottom of the connecting-rods.

Electrically, the Studebaker car is Wagner equipped. The starting and lighting system is a two-unit outfit with the motor and generator both mounted on the right. The generator is mounted vertically and driven from the helical gears in mesh with the crankshaft gear. The starting motor engages the crankshaft through a chain drive and is provided with an over-running clutch which releases the starter when the engine is running.

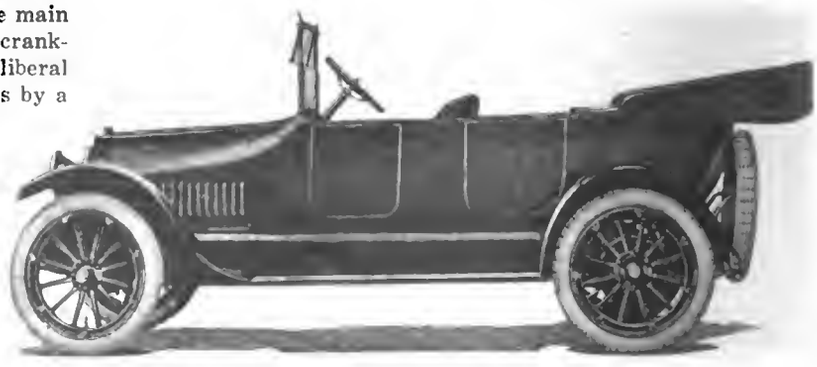
The torque exerted on the crankshaft is over 200 ft. lb., the energy being supplied by a three-cell, 6-volt, 100-amp.-hr. Willard battery mounted under the front seat. For ignition there is a Remy coil and distributer. The headlights can be focussed on any spot desired, and these, together with the dimming device, speedometer and tail lights are controlled by dash switches.

Single Wire System Used

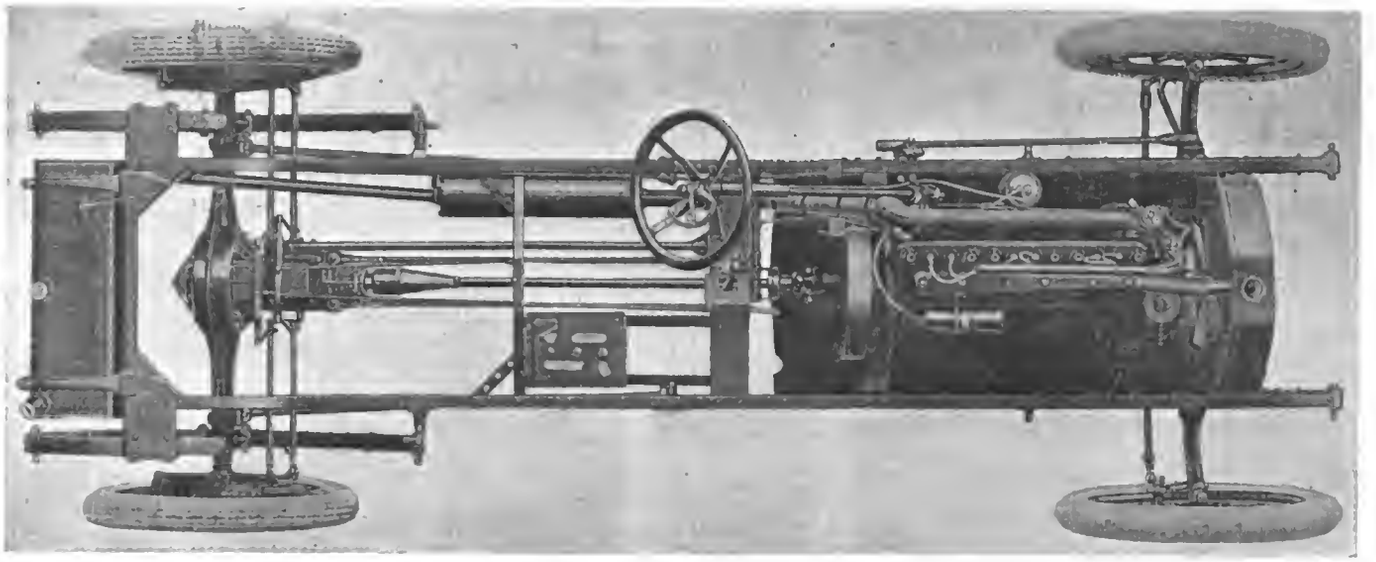
Particular attention has been given to the wiring which is a single system, grounded-return, with the wires carried in flexible metal conduits. The feature introduced last year of placing a junction box on the rear right side of the engine, where it is very accessible, is continued. All the wires go to this box and there are practically none on the body except to the control apparatus on the cowl. Four screws hold the cover plate on the junction box, giving access to any of the connections for the entire system. When the body is removed from the chassis there is no need to make a number of disconnections and furthermore the connections should not work loose, as they are all very rigid. The entire system operates at 6 volts.

The clutch has a pressed cone, the facing being mounted on easy-engaging springs and the throw-out device connected to a ball bearing collar. The drive is direct from the rear clutch member to the gearset at the rear through a 1 5/16 in. alloy steel propeller shaft fitted with a universal at each end. The gearset is bolted by means of a flange to the pressed steel housing of the rear axle and carries on its left side a torsion rod which connects to the main cross member of the frame just behind the forward end of the propeller shaft.

There are also two radius rods which are attached to the side members of the frame with flexible connections to allow for rear spring action, while preserving the alignment of the rear axle. A gear reduction at the axle of 4 to 1 on the



Studebaker series 18 seven-passenger touring car

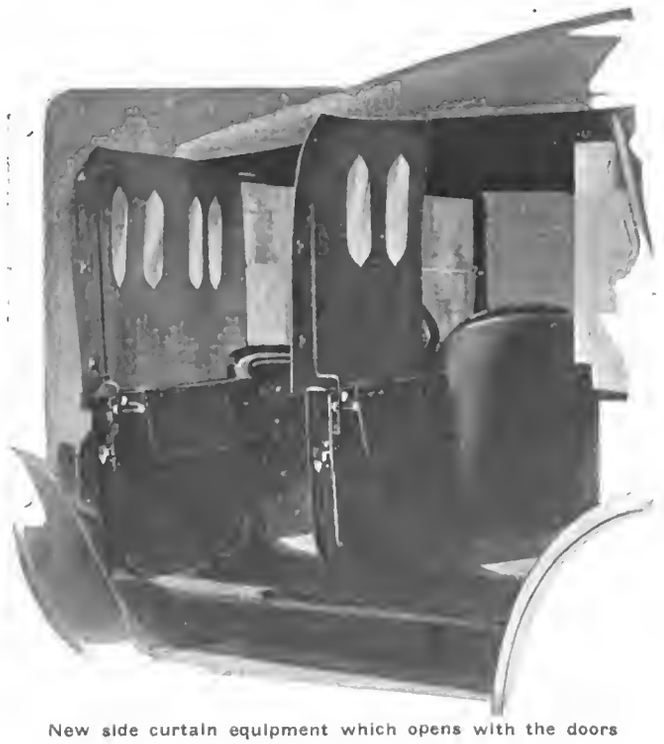


Plan view of the series 18 Studebaker six-cylinder chassis, showing layout of driving and torque members

four and 3.7 to 1 on the six is employed. The three-quarter elliptic spring suspension adopted last year has been continued, the springs being underslung beneath the axle. On both cars they are 51 in. in length with 38-in. front springs.

Wheelbases Differ

On account of the greater engine length there would naturally be a longer wheelbase on the six than on the four. There is a 10-in. difference in this respect, the four having 102 in. and the six 112 in. The tire equipment is 34 by 4 straight side on both cars. Non-skid safety treads are furnished in the rear, while each car is provided with a tire carrier at the rear of the body, together with an extra demountable rim. The wheels are artillery type covered by heavy pressed steel crowned fenders with clear running boards covered with corrugated rolled aluminum. The brakes operate on a 15-in. drum, the service brake having a 2-in. face width and being a contracting type. The hand brake is expanding and has a 1¾-in. face width. The steering gear is an irreversible, full worm-and-wheel type.



New side curtain equipment which opens with the doors

The body line is complete on both the four- and six-cylinder chassis, the cars now listed including the following:

Four-cylinder models:	
Chassis alone	$850
Roadster	930
Touring Car	940
Every-Weather Car (Convertible)	1,140
Landau Roadster	1,150
Six-cylinder models:	
Chassis alone	1,090
Roadster	1,170
Touring Car	1,180
Landau Roadster	1,350
Every-Weather Car (Convertible)	1,380
Touring Sedan	1,700
Coupé	1,750
Limousine	2,600

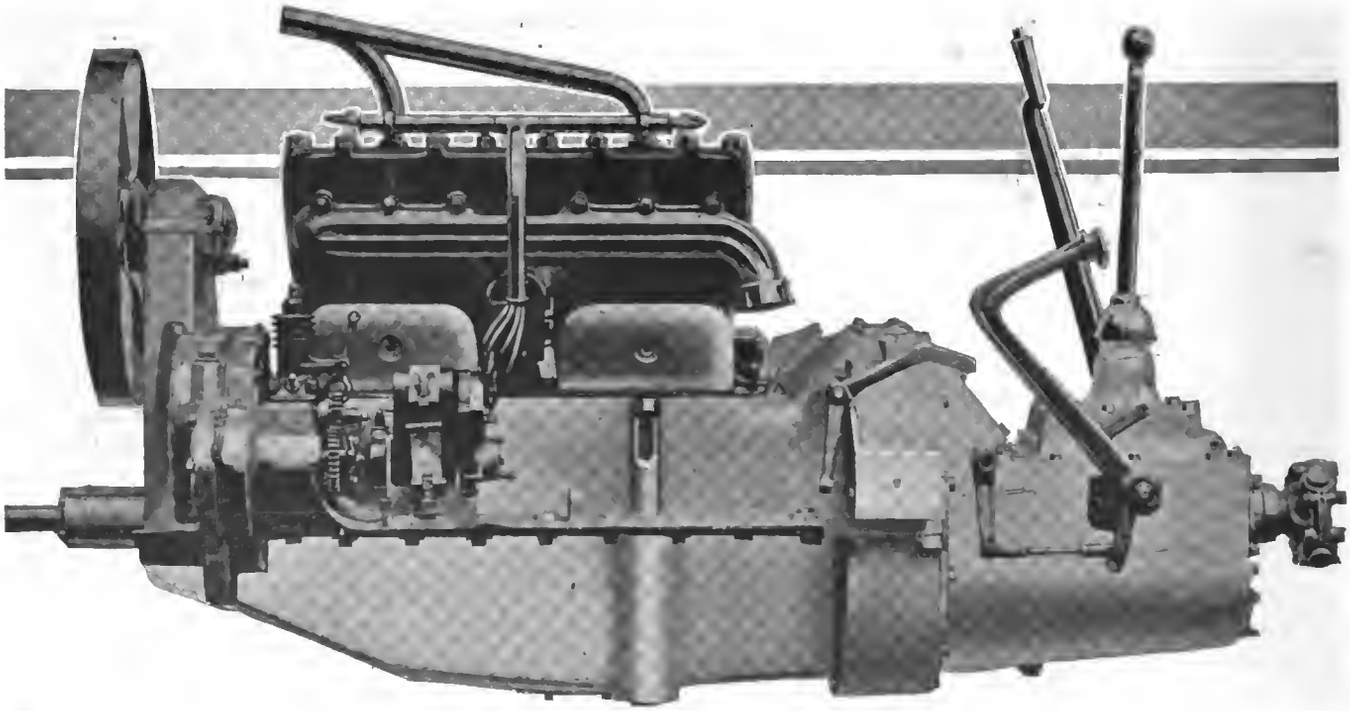
Complete equipment is included in the purchase price, which in all cases is f. o. b. Detroit. The upholstery in the touring and roadster models is straight-grained leather, while the sedan, limousine and coupé can be finished in many different shades and patterns with bedford cord and cloth upholstering. The side seats and back are finished in the same quality and workmanship as the cushions. In the sedan, limousine and coupé the carpet matches the upholstering. The front seats are divided and shaped to fit the back.

Windshield Is Adjustable

One of the features of the equipment is the windshield, which is a special adjustable type designed to fit snugly to the body. There is an overlapping portion of the upper glass which shuts out rain and snow. The steering wheel is 18 in. in diameter, and some of the additional equipment includes the leather covered instrument board, Stewart-Warner magnetic speedometer, battery indicator, oil pressure gage, carbureter control, gasoline gage on rear tank, Yale switch lock, Sparton horn and complete set of tools.

Pocket Book on Gearing

MANY useful tables and much data relating to gearing is contained in a little booklet issued by the Van Dorn & Dutton Co., gear specialists of Cleveland, Ohio, which they will be pleased to send to any engineer who will write them for a copy. Circular pitch, diametral pitch and metric pitches are all dealt with and there are long tables of conversion from diametral to circular giving the thickness of tooth, depth of cut, etc.: Formulas for strength of teeth and general information concerning bevel and spiral gearing are included.



Exhaust side of the new sixteen-valve, four-cylinder unit power plant which is a feature of the 1917 White. Note power tire pump mounting and magneto drive as well as inclosed fan drive

White Four Has Sixteen Valves

Two Wheelbase Lengths Provided on Otherwise Identical Chassis—Valves Are Set at an Angle

(*Continued from page* 949)

and in the experimental laboratory regarding the necessity for having the highest possible volumetric efficiency have been applied. As pointed out in the recent engine review in THE AUTOMOBILE, throughout the entire industry the motor engineers have realized that the way to success along the lines of thermal and mechanical engine efficiency is by securing the closest possible approach to 100 per cent filling on the intake stroke. The White company sums up the situation in the words, "valve efficiency is more important than the number of cylinders," and has used the sixteen-valve design to attain this end.

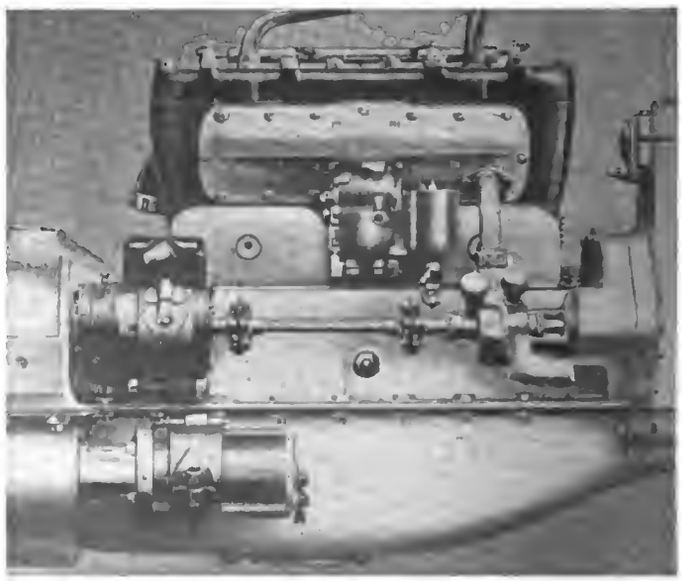
The White company advances nine reasons for the choice of the sixteen valve four. These are:

1—Greater volumetric efficiency.
2—Smaller valves for the same area.
3—Longer duration of maximum gas flow.
4—Cleaner scavenging.
5—Reduction of carbon deposit.
6—Reduction in number of times tuning is necessary.
7—Easiest course of gas flow.
8—Elimination of dead gas pockets.
9—Minimum area of combustion chamber wall.

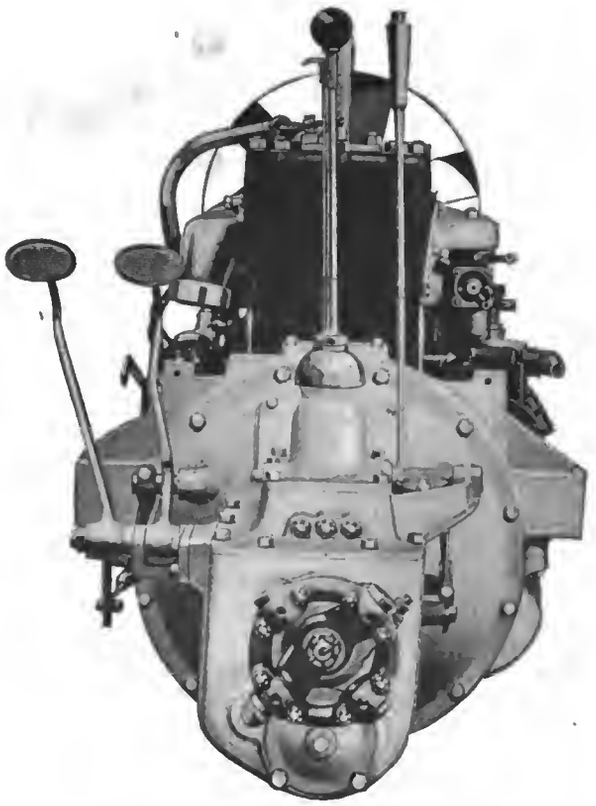
The chassis is made in two wheelbase lengths of 137½ in. for the touring, limousine and landaulet and 124½ in. for the runabout, sedan and coupé. With the exception of the wheelbases the two chassis are identical.

The Unit Power Plant

Combined as a single member, the engine, clutch and gearset form a unit power plant with three-point suspension. The 4¼ by 5¾-in. T-head cylinders are cast in a single block with the valves located at the four-corners of the square about the cylinder circle in the plan view. The cylinders are cast with an open arch between the second and third or middle two cylinders, for lightness this also serving as a factor in preheating the carbureter air. The head casting is entirely separate and contains no valve plugs, an unusual fact in conjunction with a T-head engine. The spark plugs



Intake side of the new White engine, showing mounting of carbureter and electrical units



Rear end view of the White sixteen-valve unit power plant, showing forward universal and control member mounting

are screwed directly through the head and fall in the diametric center of the cylinder, thus giving a symmetrical area for flame propagation and freedom from gas pockets. When the head casting is removed by taking out about fourteen studs, the spark plugs come off with it.

Removing the head exposes the valves and the combustion chambers, rendering the former free for grinding and the latter for cleaning. It takes 15 min. to remove the head and about 5 min. to take off all the side cover plates for the valves, to get at the springs and adjusting nuts.

The piston and rod assemblies are what would normally be expected in a high-speed engine of these dimensions. The pistons are aluminum alloy with three rings and other reciprocating weights have been kept low. The rods are drop-forged I-beams, and the crankshaft is carried on three main bearings which are lined with die-cast babbitt. The shaft is put into running balance by a series of counterweights.

There are two independent camshafts each carrying eight cams. These are driven by helical gears off the crankshaft, the timing gears being located in an independent case at the forward end of the crankcase. Stiffness is a feature of the camshaft to take the torsional stress of the eight valve springs, and the shaft is supported in five bushed bearings.

Valves Are Set at an Angle

A feature of the valves is that they are set on an angle to the vertical center plane. The principal reason for this being that it reduces the size of the combustion space and allows ample water space round the valves. Lubrication is by the full pressure system without splash. The pump is a gear design which leads the oil under a varying pressure commensurate with the speed of the engine to the main bearings. The shaft is hollow and the crank cheeks are also drilled, leading the oil directly to the lower rod bearings under pressure. The pistons and the cylinders are taken care of by the spray from the cranks and the oil then returns through a double bottom strainer to the aluminum crankcase reservoir in the bottom of the crankcase. All the bearings are carried in the upper half of the crankcase, so that when the pan is dropped the main and lower rod bearings are accessible for adjustment. By dropping the pan and removing the lower rod bearing caps the piston and connecting-rod assemblies can be withdrawn through the top of the cylinder, thus eliminating the necessity for removing the cylinder block.

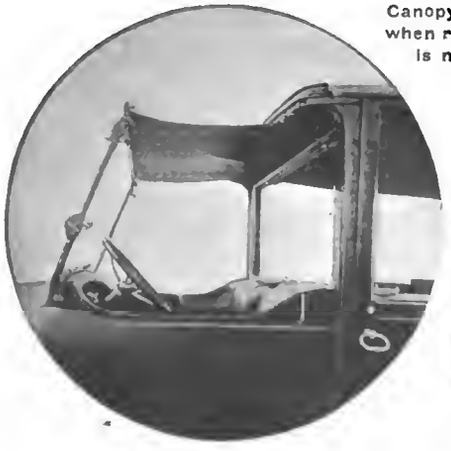
There is a level gage on the side of the crankcase, operated by a float which keeps the driver informed as to the oil supply. The condition of the feed is determined by the pressure gage. Former White cars have carried the oil supply in a dash reservoir. In keeping with the accessible design of the engine there is a removable plate through which the strainer can be taken from the crankcase and cleaned, and there is also a hand hole which allows of access to the inside of the case.

Vacuum feed is used for the gasoline system, the tank being mounted at the rear. The carbureter is a White barrel type of throttle bolted to a new design of intake. There is no header between the carbureter and the intake manifold to which it is attachd by a horizontal flange, the hot air passes through the arch in the center of the cylinder casting with a new type of adjustable stove attached to the exhaust pipe.

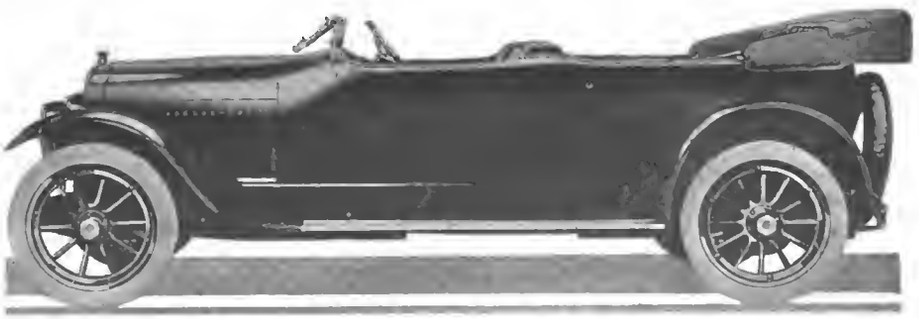
Provision for Heavy Fuel

As considerable attention is being paid to the heavier grades of fuel, the stove is of interest. There is a shutter valve on this, the air thus admitted being much cooler than that which enters the slot directly in the stove. The more the shutter is opened the greater the supply of cool air admitted, and the adjustment naturally depends on the atmospheric temperature. An accessible feature on this adaptation of the White carbureter is that both nozzles can be removed as a unit for cleaning by taking out two exterior bolts. The only adjustment on the carbureter is a knurled nut which governs the proportions of the mixture.

Pump circulation is used for the cooling water, with the pump on the generator shaft. The fan is a built-up alu-



Canopy for use when roof extension is not carried



White 1917 seven-passenger touring car which is fitted with the new sixteen-valve four-cylinder unit power plant. It sells for $4,600

minum unit with six blades and is driven by silent chain, the latter being inclosed. Adjustment of the fan drive is secured by placing the fan sprocket on an eccentric unit which is turned by a rack and pinion housed in the chain case. There is a nut connected with the pinion outside the case and when this is turned the adjustment is made by altering the center distance between the fan sprockets.

Two-Unit Electric System

For lighting and starting the Leece-Neville two-unit system is used and for ignition there is a single high-tension magneto. The generator is bolted to the crankcase at the right rear end, between the pump and generator, which are on the same shaft, there are two flexible couplings. The junction box is directly on the top of the generator.

Bendix gear connection is used between the electric starting motor and the flywheel ring gear. Current is supplied by a 12-volt, 75-amp. Willard or Exide storage battery, this voltage being used throughout all the circuits, and the two-wire system is employed.

A single plate, fabric-faced clutch running in oil is used. This delivers the power to a White four-speed gearbox which is over-geared on fourth. The shift is redesigned and, for the first time, the White company is using the cane type. The shifter is mounted on the cover of the gearbox following usual unit power plant practice. The gearset is carried on ball bearings and there is a removable plate at the bottom of the box through which the layshaft may be withdrawn, saving an hour at least on a repair job at this point.

Hotchkiss Drive Used

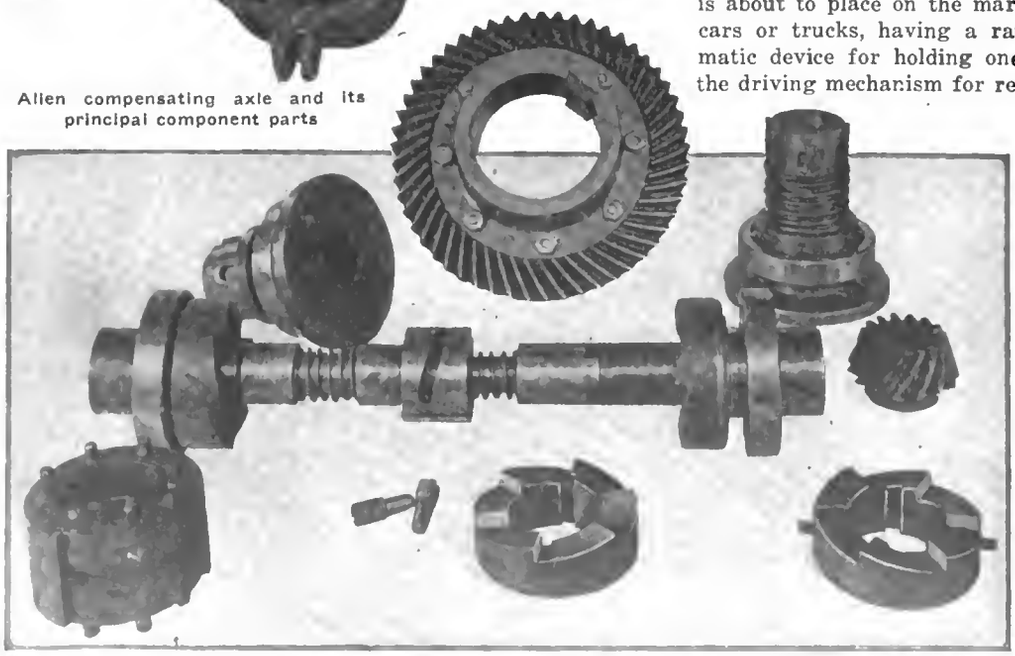
Two universals and a telescopic joint are used in the drive to the semi-floating rear axle and the hollow shaft is of chrome nickel tube. Both torque and drive are taken through the 60-in. semi-elliptic springs which are underslung beneath the rear axle. The drive connection is at the front end of the spring. There is a kick-up in the rear of the pressed steel channel frame. The brakes are on the rear wheels and the tire size is 37 by 5-in. all around with Goodyear and Goodrich cord tires optional. The extra tires are carried in the rear on forged brackets bolted to the frame and an extra rim is furnished as regular equipment. Steering is by worm and sector.

All the bodies mounted on the sixteen-valve four-cylinder chassis are new. The touring car is a center cowl divided front seat design with sloping windshield. A handy point is the mounting of all the switches and the carbureter control on the steering column. The color finish is optional within limits and there is a new design of one-person top which the White company calls the Mono-top. Full equipment including a power-driven tire pump is included in the purchase price, which for the touring car is $4,600.

Clutch Drives in Allen Axle

Differential Replaced by Ratchet Clutches —Drive on Inner Wheel on Turns

Allen compensating axle and its principal component parts



IF it were not for the necessity for providing a reverse gear, a very good automobile axle could be made by simply driving the two road wheels through ratchet clutches, so that the outer wheel on a turn would over-run the inner wheel, the latter doing all the driving. Such an axle, however, would not permit of reversing, and the engine would not be driven by the car in coasting, making it impossible to take advantage of the engine friction to provide braking effect.

The Allen Compensating Axle Mfg. Co., Philadelphia, Pa., is about to place on the market a new design for passenger cars or trucks, having a ratchet drive and a simple automatic device for holding one of the rear wheels rigidly to the driving mechanism for reversing or when the axle drives the engine.

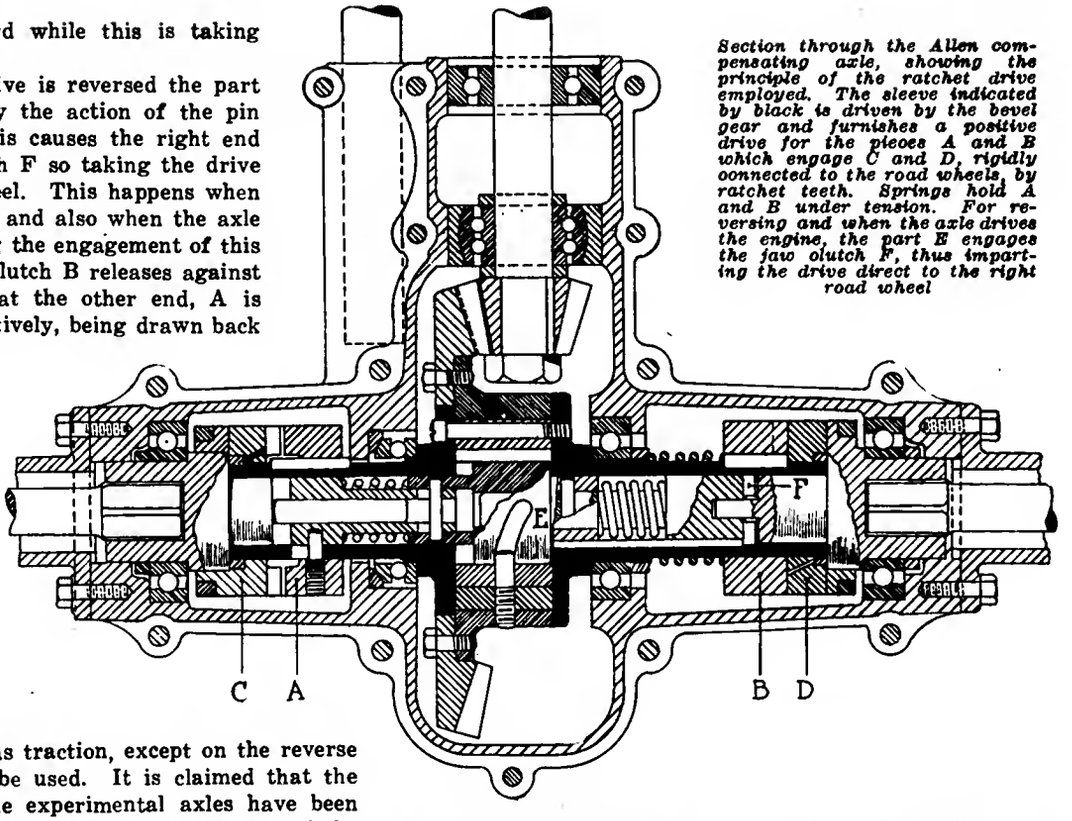
In the sectional view the sleeve shown in black is driven by the bevel gear and drives positively the two pieces A and B having ratchet teeth engaging the parts C and D which are connected rigidly to the road wheels. The springs which hold A and B up to their work are seen inside the black sleeve on the left and outside on the right. In forward driving the springs keep the ratchets engaged, but when a turn is made the outer road wheel over-runs the clutch on that side releasing against its spring. It is stated that the click of

the ratchet cannot be heard while this is taking place.

When the direction of drive is reversed the part E is moved to the right by the action of the pin and helical slot shown. This causes the right end of E to engage a jaw clutch F so taking the drive direct to the right road wheel. This happens when the reverse gear is engaged and also when the axle over-runs the engine. During the engagement of this reverse clutch the forward clutch B releases against its spring, but the clutch at the other end, A is held out of engagement positively, being drawn back by the movement of E as can easily be seen by following the details of the drawing.

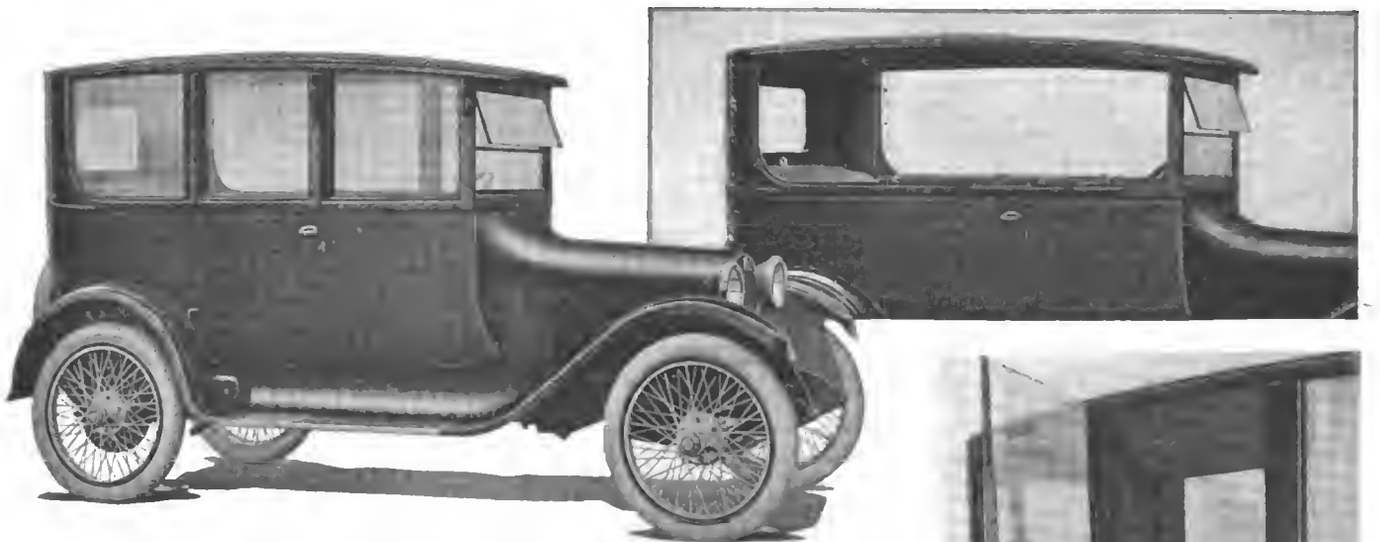
As soon as forward drive recommences the movement of the pin in the helical slot releases the reverse clutch and allows the main clutches to operate as before.

With this axle it is not possible to spin a wheel that loses traction, so there is always driving power for the wheel that has traction, except on the reverse where only one wheel can be used. It is claimed that the extensive tests to which the experimental axles have been put on heavy touring cars show that the elimination of the usual differential reduces the tendency to skid on applying brakes almost to vanishing point, since locking one brake cannot put a reverse drive on the other. It is planned to produce the Allen axle as a replacement part for several of the popular cars and also as a manufacturing proposition.



Section through the Allen compensating axle, showing the principle of the ratchet drive employed. The sleeve indicated by black is driven by the bevel gear and furnishes a positive drive for the pieces A and B which engage C and D, rigidly connected to the road wheels, by ratchet teeth. Springs hold A and B under tension. For reversing and when the axle drives the engine, the part E engages the jaw clutch F, thus imparting the drive direct to the right road wheel

Elegance in New Dodge Convertible Sedan



DESIGNED for use in either Summer or Winter, the new convertible sedan brought out by Dodge Bros., Detroit, is marked by conservative lines in which the influence of the latest American and European body styles is evident. The color scheme of the interior is gray with a bluish tint, a striped effect being carried out in the upholstery, curtains and flexible robe cords, with carpet, front compartment floor and running board coverings also gray. Cushions are of the Turkish type, upholstered in gray and trimmed with narrow lace. All fittings are nickel fitted and there is flush dome light. The front seats are divided.

The rear side windows may be removed and concealed in a narrow compartment in the back of the rear cushion. The other windows lower out of sight and the pillars may be carried under the rear seat. The sedan sells for $1,185, f.o.b. Detroit.

Four-Cylinder Best Tractor Engine

Tests of a Number of Engines Show Great Variations in Performance—Valve Timing Varies Greatly

By A. A. Potter and W. A. Buck

THE following gives the gist of an interesting account of investigations into the efficiency of tractor engines, and is extracted from a paper presented at the December meeting of the A. S. M. E. While many other engineers may not agree with the authors' conclusions, they have compiled their data carefully and the tables give information that cannot fail to be of value to tractor-engine manufacturers.

Authors' Conclusions

From the results of this investigation the authors have derived the following general conclusions:

The four-cylinder motor is better adapted for belt work on account of the greater number of impulses per revolution.

The single-cylinder motor and the two-cylinder motor operate better than the four-cylinder motor with fuels heavier than gasoline.

Carbureter Requirements

Carbureters now used are satisfactory for gasoline, but a carbureter jacketed with heat from exhaust gases should be employed when operating with kerosene or with the heavier fuels.

The ordinary automobile motor is too light for traction-engine work. The traction-engine motor should operate at lower piston speeds than the automobile motor. Motors operating at piston speeds of 700 to 900 ft. per minute are giving satisfaction.

Vertical Engines Preferable

The vertical types of motors are preferable on account of longer life and greater accessibility.

The valve-in-the-head type of motor has the more efficient combustion space and is to be preferred to the T-head or L-head types.

The combination of the forced feed and splash oiling system gives good results.

Jump Spark Ignition

The jump-spark system, on account of its mechanical simplicity, is the best system of ignition for traction engines of more than one cylinder.

The fuel-economy range is from about 1.30 lb. per brake horsepower per hour at one-fourth load to about 0.7 lb. per hour at full load. The fuel consumption in pounds per brake horsepower per hour is very nearly the same for both gasoline and kerosene.

Thermal Efficiencies

The thermal efficiencies at full load vary from 14.88 to 19.8 per cent for gasoline fuel, and from 13.7 to 15.97 per cent for kerosene.

The results of the tests relating to fuel consumption and thermal efficiency are given in Table 2. The lower fuel economy of the tests recorded for engine A as compared with tests on engine B (the same engine) was due to the difference in the spark advance. During the operation of engine A a greater spark advance was used, and more cooling water had to be injected into the cylinder with the fuel to prevent preignition. Water injection had to be used also during the tests of several engines with gasoline fuel (engines D, E and F).

Table 2. Fuel Consumption and Thermal Efficiency of the Traction-Engine Motors Tested

Engine	Per Cent of Full Load	Fuel per Hour per Shaft, Hp., Lb.	Thermal Efficiency, per Cent
	57.8	0.963	13.43
	99.8	0.808	15.88
	70.8	1.032	12.53
A	38.2	1.683	7.67
(60 B.H.P.)	111.3	0.928	13.93

[1]With mechanically operated inlet and exhaust valves.
[2]High-speed throttling type of governor that regulates the quantity of mixture.
[3]With K-W impulse starter magneto.
[4]Diaphragm type, using pressure of circulating water to control the speed.
[5]Valve in the head.
[6]Make-and-break system using an Accurate oscillating magneto.
[7]High frequency belt driven K-W magneto with trembler coil.

In the case of several engines the valve setting had to be changed before satisfactory operating conditions could be secured. In one case the preliminary tests indicated that the carbureter was too small for the engine. In order to facilitate comparison of various types the motors of the tests were grouped as follows:

Group I—Motors which develop at full load 15 to 26 hp. on brake. The tests recorded for motors H, J, K, L and M are included in this group.

Group II—Motors which develop 26 to 51 b.hp. In this group belong the motors recorded in the tables as D, E, F and G.

Group III—Motors which develop more than 51 b.hp. The tests recorded for motors A, B and C represent this group.

Average Fuel Economy

The average fuel economy for the various groups appears in the table at the right.

From the data on Group I and Group III Table 3 has been computed. Computations could not be made for Group II, as the engines in this class were not operated on kerosene. Table 3 shows the advantages of the kerosene-burning engine. Considering Group I, 10.07 gal. of kerosene will deliver as much power as 10 gal. of gasoline. With kerosene at 10 cents per gallon and gasoline at 20 cents, the cost with gasoline fuel will be 1.99 times that with kerosene fuel for the same power developed. Considering Group III, 12.32 gal. of kerosene will deliver as much power as 10 gal. of gasoline. This gives a ratio of 1.62 to 1 with prices of fuel at 10 cents per gallon for kerosene and 20 cents for gasoline. The advantages of the kerosene engine are offset to a greater or less degree, depending upon the operator, by the added trouble in handling. The life of the motor will also be somewhat shortened when using kerosene fuel. To this should be added the lower reliability with the heavier fuel. In some work done by traction engines reliability is the main factor.

Valve Timing

A study of the valve timing of the different motors in these tests shows no uniformity, except that the majority of the motors are so timed that the inlet valve does not open until after the exhaust valve is closed. The timing given in Table 4 is offered as a result of the authors' study and experience with traction engines.

TABLE SHOWING AVERAGE FUEL ECONOMY FOR THREE MOTOR GROUPS

Per Cent of Full Load	Fuel Consumption, Lb. per B.H.P. per Hour				
Group	Gasoline 1	Kerosene I	Gasoline II	Gasoline III	Kerosene III
25	1.853	1.990	1.416	1.47	1.827
50	1.147	1.265	0.893	0.93	1.190

Should Study Car Balance

Roadworthiness Equivalent of Seaworthiness and Different from Roadability—Proper Distribution of Weight on Front and Rear Axles Vital

By "Mercury"

WHEN a naval architect undertakes the design of a vessel, he must know accurately the weight and position of every bit of material which will enter into the construction. The sum of the weights must be exactly the displacement on which he has figured, to bring the ship to the water line he has laid down; they must be equally disposed on each side of the center line, so that she will float on an even keel; they must be properly distributed fore and aft, so that she may ride easily on the waves. Too much weight in the bow or the stern will make her steer wildly or plunge heavily into the seas; a lateral concentration of the weight will cause her to roll violently; while if her center of gravity is too high, she may be in danger of being rolled over by a beam sea, a menace to the lives of her crew and the safety of her cargo. In every part, the exact distribution of the weight must conform to the rules of science or the dictates of judgment and experience.

Weight Distribution

So this question of weight distribution has become as much a part of the work of those who design the carriers of the sea, as the determination of form, power and strength. In the design of the carriers of the land, it has received considerably less attention, although there seems to be little doubt that, as the distribution of weight in a ship affects the seaworthiness of the vessel, so the distribution of weight in an automobile affects its "roadworthiness." Perhaps some of this lack of attention may be explained by the fact that while water is a yielding medium which quickly makes apparent any defects in the distribution of the weights, the automobile rests on a solid base, and defects of this nature are not so readily discoverable. Perhaps also, "roadworthiness" is such an indefinable thing that it is difficult to formulate any rules in regard to it.

On the other hand, seaworthiness is also an indefinable thing, but although its attainment was for centuries, and still is, largely a matter for judgment and experience, nevertheless, many logical thories and some exact rules have been produced that have well-nigh revolutionized the art of ship design. While we can hardly expect theories and rules to be propounded within a few years, which in a similar case have required centuries for their production, nevertheless so many and such active minds have in recent years been concentrated upon automobile design and so much energy and wealth have been devoted to the attainment of perfection in automobiles, that it seems remarkable that more serious attention has not been given to this particular subject of the distribution of weight.

Old Models Often Superior

Many of our latest and most up-to-date designs suffer from this lack of attention, which is made only more apparent by their high degree of refinement in other directions. The ability to attain a high speed is a very useless accomplishment if that speed can only be attained on a road like a billiard table. Many a fine modern car that runs with the silence of an electric motor and that will show a fine turn of speed on the testing track, is put to shame on the road by some lumbering old Simplex or Fiat that rolls past, into the ditch and out again, with hardly a tremor, maintaining over all kinds of road surfaces a speed which the other would not dare to attempt. A plain board seat on a well balanced car may be more comfortable than the most luxurious upholstery on a car that bounces all over the road.

This is not entirely a matter of springs, as many people seem to think. One car that I have in mind, although very well sprung, is often at a disadvantage simply on account of the excessive weight of its rear axle. Another very popular car is a positive menace to its occupants and to other road users because of the high position of its center of gravity, and I have personally witnessed serious accidents which were attributable solely to this defect. Again, many chassis are entirely satisfactory when fitted with heavy touring or limousine bodies, but buck like bronchos when equipped as runabouts, while some touring cars that are quite comfortable with their full complement of passengers are very uncomfortable with only the front seats occupied.

Among the many advantages of the multi-cylinder V-sbaped engines, their compactness has often been cited, but it is also a fact that the great weight of the engine concentrated so far forward in the chassis has caused, in some cases, cars fitted with this type of engine to steer very wildly at high speed. Instances could be multiplied where "roadability" has been obtained at the expense of "roadworthiness." It is said that before the last British Tourist Trophy race, a competitor who had a very light car with a very heavy engine, arranged the engine to be movable, and by successive trials found the position of the engine in the chassis which would allow his car to maintain its best speed under the very varying conditions of the roads in the Isle of Man.

General Rules Possible

These instances simply point to the importance of this subject. While, of course, the wide variations in detail design make impossible an absolute standardization of the weight and position of each unit which enters into the construction, nevertheless it would appear that some general rules could be laid down for the position of the center of gravity, of the whole car, for the proportions which the weights of the various units should bear to one another and to the weight of the car as a whole and for the positions of these weights with respect to the center of gravity, to obtain the best balance and most satisfactory performance. Such an apparently elemental question as the proportion of the total weight which it is advisable to carry on the rear wheels is far from answered in the minds of most of us, and yet experience can readily supply a figure, which if not an inflexible rule, represents at least a satisfactory solution.

Years ago, the designer of the famous Lanchester cars, to whom we owe the introduction of the worm-drive and the wire wheel on modern cars, aroused considerable controversy by his original views on the proper distribution of weight, but since that time so little has been added to his investigations, that I think it would be extremely interesting, as well as instructive to many of us, to have the opinions both of designers and of users on this subject.

The Rostrum

Has 1905 Overhead Valve Peerless

EDITOR THE AUTOMOBILE:—I have an old four-cylinder overhead valve Peerless, No. 915, type 11. Can you tell me about what year it was made?

2—What is the gear ratio in fourth?

'—What is the horsepower rating and the r.p.m. of the engine?

4—What is the displacement of the pistons? E. A. F.

Philadelphia, Pa.

—This car was produced during the season of 1905.

2—The total gear reduction on fourth speed, which is direct drive, is 4 2/7. The maximum gear speed would, of course, be very difficult to determine on a car as old as this without some knowledge of its present condition.

3—Approximately 34 hp. figured at 1000 ft. piston speed, or roughly 1100 r.p.m.

4—The piston displacement is about 369 cu. in.

Removing Tar from Car Bodies

Editor THE AUTOMOBILE:—Supplementing my previous communication with reference to removing tar from automobile bodies, as it is a fact because tars are readily soluble in raw linseed oil, it is only necessary to apply the oil thoroughly in order to dissolve the pitch, and any convenient method of applying the oil that will not scratch the painted surface will be found satisfactory.

Would suggest, however, that the painted surface first be washed so as to remove all grit, then after same is dried apply the linseed oil with a soft rag, gently removing the spots of tar or pitch, and they will dissolve and come away from the painted surface without damage to same. Then after the pitch has been thoroughly dissolved, so that the painted surface appears to be free from same, due to the combination with the oil, then apply the ordinary wash of soap and water to remove the oil. This practice will be found more satisfactory than any other method I have ever known and is very easy to apply. H. A. M.

Philadelphia, Pa.

Cannot Change Steamer to Gas Car

Editor THE AUTOMOBILE:—I have a model 0.0 White steamer which has been run about 7000 miles. Would it be advisable to change it into a gasoline car if a suitable engine could be bought? D. O. W.

Marshfield, Ore.

—It is not practical to change your steamer into a gasoline car. Many persons have tried to do so in spite of advice that it cannot be done with any degree of efficiency. You would need a new radiator, engine, clutch, transmission and rear axle, to say nothing of necessary changes in the frame. The axle is high geared and not the right type for a gasoline car.

Timing for Model 17 Buick

Editor THE AUTOMOBILE:—Kindly give valve timing for the model 17 Buick.

Marysville, Ohio. M. M. CAR CO.

—The valves for the model 17 Buick will be correctly timed when the exhaust valve closes when piston is 1/16 in. past its upper dead center position and inlet valve opens when piston is 3/32 in. past its upper dead center. These measurements should be taken with a clearance of 0.010 in. between ends of valve stems and rocker arms when both valves are fully closed.

Wiring Diagram of 1910 Pierce 48

Editor THE AUTOMOBILE:—Kindly give wiring diagram of a 1910 Pierce 48 connecting up the coil with the battery and commutator, the original outfit of the Pierce-Arrow being used. I have been starting on the magneto and would like to have the battery to start on for the winter. H. C.

Brooklyn, N. Y.

—Wiring diagram of 1910 Pierce 48 is illustrated in Fig. 1.

Avoid Stopping on Main Highway

Editor 'THE AUTOMOBILE:—A remarkable demonstration of the wisdom of adopting and constantly living up to the principle of Safety First was given an automobilist of East Orange, N. J., recently. By exercising a little forethought he no doubt saved his wife's life and placed her in a position to safeguard his. On the side of a new and quite slippery road near Millburn, N. J., this gentleman was busy placing chains on his automobile when the thought occurred to him

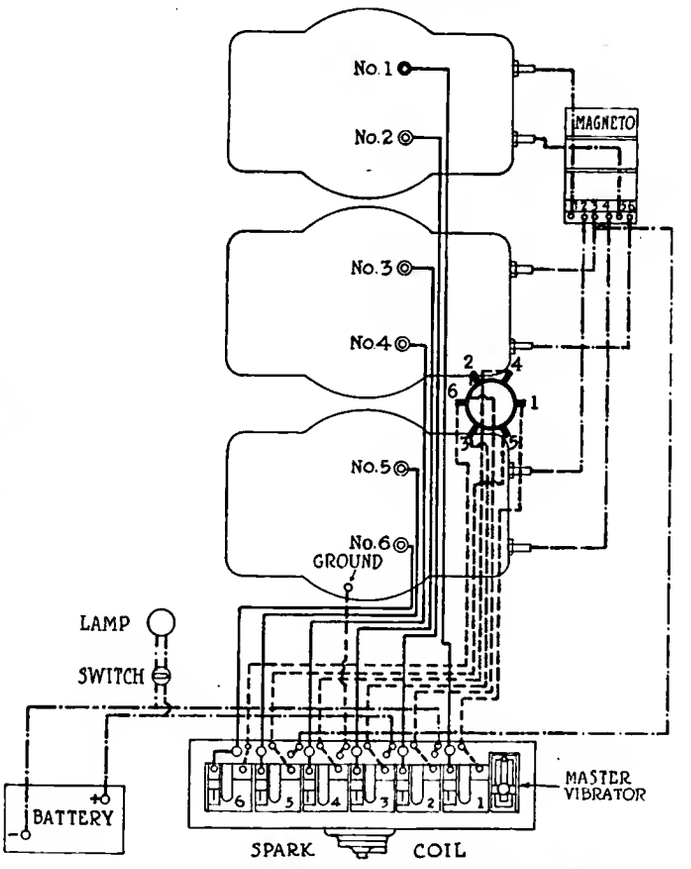

Fig. 1—Wiring diagram of 1910 Pierce-Arrow 48

that his wife, who was standing beside him, was in a dangerous position in the event of a car skidding into his.

Almost immediately after acting on his advice and stepping to the side of the car, a warning cry from her gave him sufficient time to step out of the way and avoid being struck by a large touring car which was skidding sideways and struck the rear end of his car with great force. The impact drove his car ahead, it afterward taking a course at right angles over an embankment down into a field.

This experience teaches automobilists that it is a very wise precaution and in obedience to the principle of Safety First to drive into a side street or roadway when conditions on main thoroughfares are dangerous and there stop for any needed purpose.

The fact that a part of your car is likely to stand in the way of passing cars making it necessary for the drivers to turn to one side, or possibly put on brakes, to allow traffic from opposite direction to pass—in either case inviting a skid—makes the above rule a wise one to follow.

East Orange, N. J. H. J. B.

How Delco Ignition System Operates

Editor THE AUTOMOBILE:—The Delco ignition on the 1916 Cadillac has been a puzzle to me for a long time. I have read instruction book as well as other books on it and still do not get it. Please tell me how the current travels from the battery to the plugs. Do the two breaker points break a primary circuit or does one break the primary and the other a secondary? Does the current come from the battery continuously even at high speeds or from the generator?

Brooklyn, N. Y. H. A. G.

—Current comes from the battery to each of the breakers. One breaker cares for one set of four cylinders and the other for the other set. No current is passing except when the one or other of the contacts is closed. When either pair of contact points come together the battery current passes through the primary winding of an induction coil. As soon as the points separate again the effect of stopping the flow of current suddenly like this is to cause a very high voltage current to be generated in the secondary winding of the induction coil. This high voltage current goes to the high tension distributer and this sends the discharge to the proper spark plug.

In an induction coil there is no connection between the primary and secondary coils. The former is a short coil of fairly thick wire, and outside this a great length of fine wire is wound. When current flowing through the inner coil is stopped a "surge" of high tension current is generated in the thin wire coil and the voltages are roughly in proportion to the lengths of wire in the respective coils.

At low speeds and at high speeds current is supplied by the generator, but it passes through the battery first. The battery is like a tank of water kept full all the time by a pump, the generator being the pump.

1910 Herreshoff Multiple-Disk Clutch

Editor THE AUTOMOBILE:—Will you kindly advise the number of disks in the multiple-disk clutch of the Herreshoff unit power plant in the 1910 or 1911 runabout? Also, please give the best timing for the engine. WM. M. L.

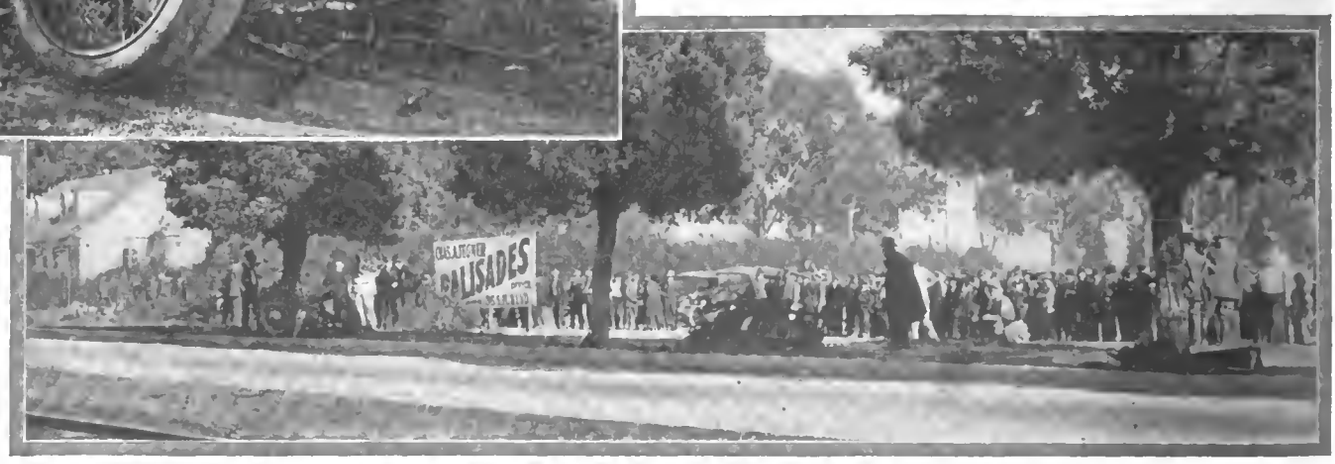
Paterson, N. J.

—There are fifteen driven and fifteen driving disks in the clutch of the Herreshoff 1910 and 1911 runabout. We are unable to furnish the timing of the motor.

A 2000-Hp. Crash at 100 M.P.H.

THE accompanying illustrations of Jackson's car wrecked in the thirteenth lap of the Grand Prize road race held at Santa Monica, Cal., Nov. 18, demonstrate the enormous amount of energy stored up in the rapidly moving car as well as the danger of modern high-speed racing cars traveling on ordinary streets and roadways. This machine was moving at 100 m.p.h. and probably weighed at least 3000 lb. It would then possess a kinetic energy of 1,007,390 ft.-lb. If this was dissipated in 1 sec. as the car struck the tree, work would be done at the rate of nearly 2000 hp. The force of the blow when the car hit the tree is equivalent to a blow from a weight of 1 ton falling freely for 500 ft.

The car hurdled the concrete curb, smashed two trees, one of which fell on a moving picture operator, killing him, and demolished a refreshment stand, killing the woman occupant and a spectator standing nearby. The car finished by wrapping itself around a third tree, cutting Jackson's body in two and hurling his mechanic, John Ghianda, 40 ft., seriously injuring him. Wreckage broke a woman spectator's arm and injured a man.



ACCESSORIES

Perry Lock Steering Wheel

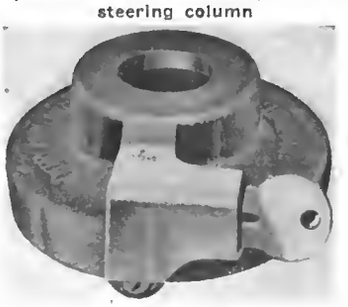
BESIDES in a complete steering wheel for any car, Perry locks are supplied to be mounted under the steering wheel on Ford cars. As shown in the illustration, the complete steering wheel is a very neat construction, the locking mechanism, consisting of a hexagon and a hub which is rigidly keyed to the steering post, being integral with the spider hub. When the car is locked, a key being used, the steering wheel has no connection with the steering column and is free to spin like a top, but when the wheel is in the driving position it is securely engaged. Different keys are supplied for every lock.

The device for Fords consists of a collar containing a locking device on the same principle as that used in the complete wheel, the steering wheel being locked out of engagement with the column. When in driving position the wheel is held as rigidly as if the lock were not used. In installing the lock no change is necessary except the replacement of the gear housing directly under the steering wheel. This can be done by anyone in 15 min.

With either of these devices the car cannot be towed or driven away as the front wheels are out of control. Price of complete wheel is $15. Ford lock sells for $5, installed.—Perry Auto Lock Co., 1238 Michigan Avenue, Chicago.

Perry lock steering wheel

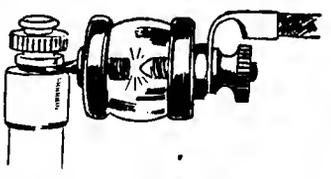
Perry lock for Ford cars in place on the steering column



Perry lock for Ford steering wheel

Marvel Spark Intensifier

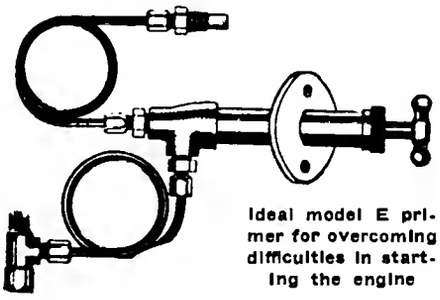
As shown in the accompanying illustration, this device embodies the principle that forcing the current to leap a gap before reaching the spark plug intensifies the spark which occurs between the points of the plug. A glass case incloses the two electrodes and the width of the gap may be readily adjusted by a small nut outside the case. Adjustment of the points is facilitated by having the spark gap in the intensifier visible through the glass. One intensifier should be fitted to each plug. The devices are neatly finished and simple to attach. Price 75 cents each.—Marvel Mfg. Co., 1020 Washington Boulevard, Oak Park, Ill.



Marvel Spark Intensifier attached to plug

Ideal Pressure Primer

The Ideal model E primer illustrated herewith is designed to overcome difficulties in starting an engine in cold weather, thus saving battery current. The primer, which is attached to the dash, is connected with the feed line and the proper amount of gasoline is injected into the manifold of the engine just before cranking. The stem is threaded and when the primer is not in use a few turns of the handle will close the valve, making it impossible for the device to leak, even under pressure. The manufacturer states that this primer can be used from one season to another without attention, due to the use of two materials on the plunger to avoid the trouble frequently experienced by the leather drying out. Special furnishings for any car are provided and directions included with each primer, the price complete with tubing and all connections being $5.—Ideal Brass Works, Tenth Street and Canal, Indianapolis.



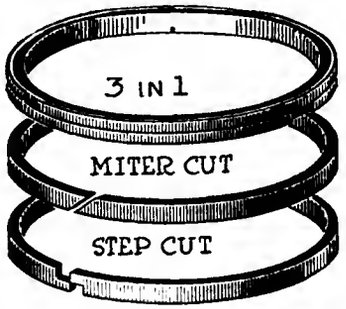
Ideal model E primer for overcoming difficulties in starting the engine

Fillometer for Fords

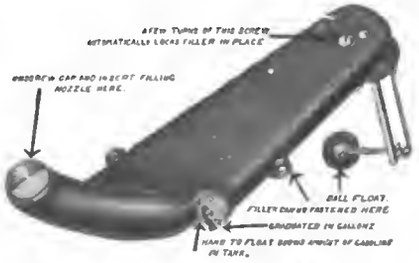
This device permits filling the gasoline tank of Ford cars without disturbing the occupants of the front seat. It consists of a metal casing that screws over the filler cap of the tank and fits flat under the seat cushion with its nozzle projecting past the edge of the seat. A gage is included that shows the amount of gasoline in the tank at all times.—Apex Electric Mfg. Co., 410 West Fifty-ninth Street, Chicago.

Stevens Non-Set Piston Rings

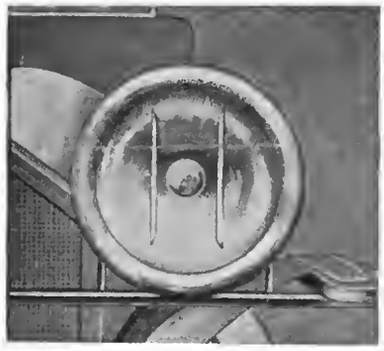
In these individually cast rings the natural skin of the casting is left in the finished ring. By the method of machining and polishing it is claimed that the resulting ring is extremely resilient and long-lived, making a gas- and oil-tight piston. Three styles of Non-Set rings are made—the miter-cut, the step-cut and the three-in-one. The latter is a compound ring made up of two narrow concentric rings lying on an inner ring in a manner that prevents any direct line for the gases to escape. Price,

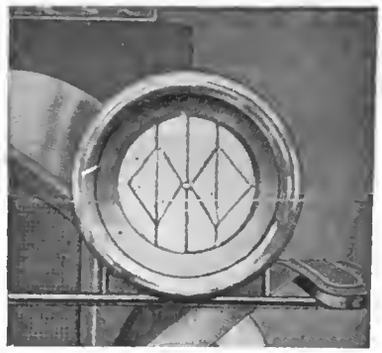


Stevens Non-Set individually-cast piston rings in the three styles made



Fillometer for filling Ford gasoline tank





Left—Hughes electric engine warmer for use in unheated garages. Above —Nodaz headlight dimmer, closed at left and open at right. The shutters employed in this device are operated by a push-button

miter-cut and step-cut, 25 to 40 cents each; three-in-one, $1 to $1.50, according to size and quantity.—Stevens & Co., 375 Broadway, New York.

Hughes Electric Engine Warmer

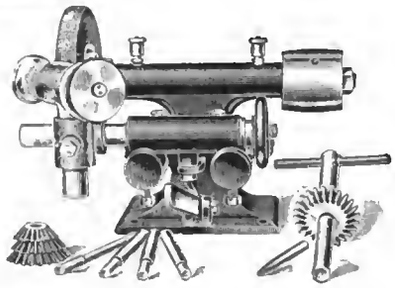
Engine and radiator are kept warm while in unheated garages by means of an electric heater operated from the lighting circuit. The heating element is inclosed in a metal case about the size of a dry battery, placed beneath the hood, and the hood and radiator covered with a blanket. The cost is said to be less than 1 cent per hour and the outfit well insulated and safe. Price, $4.—Hughes Electric Heating Co., 211 West Schiller Street, Chicago, Ill.

Walden Double Offset Wrenches

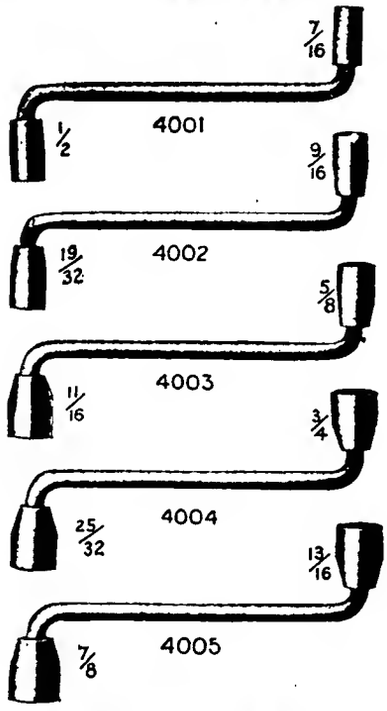
The sockets of these wrenches are placed at the end of a long handle that is bent in the form of a Z. These sockets are made of a solid steel bar, machine turned and broached to size. The handles are made of steel rod and have a length of 9 in. Price, No. 200 set, five wrenches, $2.—Walden Mfg. Co., Worcester, Mass.

Nodaz Headlight Dimmers

An electrically-operated translucent yellow shutter made in sections and installed in the headlight provides a dimming feature. When closed these shutters appear as narrow strips, permitting the searchlight beam of light to shine unrestricted. Pressure on a push-button near the driver's hand opens the shutters, causing the beams of light to pass through the translucent yellow material. Though giving a good driving light and a strong light at both sides of the road, glare is prevented, it is said. This company also makes a small rheostat for dimming headlights. Price, $10. —Ward Leonard Electric Co., Bronxville, N. Y.



Nasco valve grinder designed to secure any desired bevel



No. 200 set of Walden double socket offset wrenches

Nasco Valve Grinder

For grinding poppet-type valves to any desired bevel. A spindle, driven from an overhead shaft, carries a grinding wheel. The valve is carried in a swiveled chuck rotated by a small round belt, or, if desired, by hand. It is claimed to grind any valve to a perfect seat in 1 or 2 min., and not to require a skilled mechanic to operate it. Valve-seat reamer for refinishing the valve seats is also included in the set. Price, complete, $30.—National Auto Specialty Co., Tama, Iowa.

Bailey Muffled Heater

This heater is operated by the exhaust gases and is designed for either open or closed cars. The heater consists of a valve placed in the exhaust line between the engine and muffler. From here the gas passes through flexible tubing to a muffled seamless tube. The radiator lies flush with the floor and has an ornamented grilled nickel-plated surface. Price, $12 complete.—Riverside Machine Works, 228 Croton Avenue, New Castle, Pa.

No-Leak-O Piston Rings

The No-Leak-O piston ring is made of one piece. A groove is cut in the ring at right angles with the face and sloping downward for oil sealing. It is the oil sealing feature which is claimed to make the device proof against leaking. On the downward stroke of the piston the square edge of the ring will gather the surplus oil from the cylinder wall and pull it toward the oil pit. On the up-stroke the oil is distributed again on the cylinder wall from the sloping face of the groove. List prices range from 50 cents to $1.30, depending on the diameter.—Automobile Accessories Co., Baltimore, Md.

Bailey combined heater and muffler. It is easily and quickly applied

Industrial Miscellany

Factory

House Wire Wheel Co., Buffalo, N. Y., recently formed, is making arrangements for the erection of a plant for the manufacture of wire wheels for automobiles on a site recently acquired.

E. H. Sprague Mfg. Co., Omaha, Neb., has been formed to manufacture automobile accessories. It has taken over the plant of the Standard Foundry Co., that city.

Adams-Bagnall Electric Co., Cleveland, is completing an addition to its factory including a complete porcelain-enamel plant. Porcelain-enameled reflectors are largely used for industrial lighting.

Saxon Mfg. Co., Toledo, is planning to build a factory to manufacture automobile accessories.

Willard Storage Battery Co., Cleveland, has taken out a permit for interior improvements on its plant in this city. It will also build an $85,000 two-story plant, 135 by 222, at 280 East 131st Street.

Michigan Hearse & Motor Co., Grand Rapids, Mich., is building an addition to its plant. The addition is to be 100 by 60 ft. and will be devoted to the construction of bodies.

Specialty Mfg. Co., Minerva, Ohio, has been formed to manufacture automobile accessories. It will begin operations at once by the manufacture of an automobile light adjuster or tipper to be used in the place of a dimmer. Manufacturing will be concentrated in the Central Garage for the present.

Orrville Rubber Co., Orrville, Ohio, has started manufacturing tires and tubes.

Alpha Rubber Mfg. Corp. will locate in Genoa, Ill., to manufacture automobile tires and tubes. Up to this time the corporation has been selling a product manufactured expressly for it. Seventy-five employees will be worked in the new plant. J. A. Berger is president and general manager; Carl Schneider is vice-president.

Guarantee Tire & Rubber Co., Indianapolis, has been incorporated with a capitalization of $70,000 to deal in tires. The new company supersedes the Guarantee Tire Co. The officers are: G. F. Kreitlein, president; C. W. Minesinger, vice-president and treasurer, and Walter W. Kuhn, secretary. The company has taken over a five-story building at 214-216 McCrea Street for storage purposes.

Metallic Rubber Co., Columbus, Ohio, a subsidiary of the United States Rubber Co., did not open for operation Dec. 1, as was planned, because of delay in securing deliveries of machinery. The concern has taken over the former plant of the Midgley Manufacturing Co., on Dublin Avenue.

International India Rubber Co., South Bend, will begin the manufacture of automobile tires early next year. The first unit of the plant is nearing completion. The tread patterns for the tires to be manufactured by the company have just been patented.

Personal

Walter Woods and J. A. Clark are executives in the Van Cortlandt Vehicle Corp., New York Peerless representatives. Mr. Woods is vice-president and Mr. Clark is sales manager. Mr. Woods was formerly connected with the Peerless factory branch in New York. Mr. Clark managed the sale of the Peerless cars in New York for many years.

W. E. Heye, formerly with the Sharpleigh Hardware Co. of St. Louis, has been appointed traveling representative of the Gibson Co., Indianapolis, state Overland distributer and accessory dealer. He will have headquarters in South Bend, Ind.

Charles Campbell has been appointed manager of the used-car department recently installed by the Missouri-Haynes Co., Kansas City. He was formerly with the Moriarty Motor Co.

H. P. Nelson has been elected treasurer and sales manager of Robert Lurie & Co., New York, Metz representatives.

Henry McLaughlin has been appointed factory manager of the Detroit plant of the Lewis Motor Corp. He was formerly superintendent for Golden-Belknap & Swartz.

E. H. Gertz will manage the Mount Vernon and New Rochelle branches of the Hudson Motor Car Co., New York. He assumed his new duties Dec. 1.

F. E. Dennison has joined the sales department of the Hartford, Conn., branch of the Packard Motor Car Co. of New York and will manage the used-car department.

H. S. Jackson of New York has gone to Portland, Me., to manage the Gilson Automobile Co., Mitchell agent.

J. A. Lamkin, formerly of Boston, Mass., has gone to Portland, Me., as sales manager for the D. E. McCann's Sons Co., agent for the Smith Form-A-Truck.

W. M. Williams has opened a general advertising office at 132 South Salina Street, Syracuse, N. Y. Mr. Williams during the past year was a member of the advertising department of the Willys-Overland Co., Toledo, and previously was the advertising manager of the Franklin Automobile Co. for 2 years.

Dealer

De Lion Tire & Rubber Co., New York, has moved to 1922 Broadway.

Saxon Motor Co., New York, has moved to 1744 Broadway. The old store at 251 West Fifty-seventh street will be retained for display purposes.

A. J. Picard, metropolitan distributor for U S L batteries and national distributor for the Genemotor, has purchased the interest of E. S. Morrison in A. J. Picard & Co. Mr. Picard has incorporated his business and will continue under the old name of A. J. Picard & Co. A five-story building is being erected at 9 West 61st Street, which will be ready for occupancy on or about March 1, 1917.

Everard & Oberting Co., Columbus, Ohio, will distribute Macon cars in central Ohio territory. Sales offices are at 140 West Blake Avenue.

E. B. Fidler, Marion, Ohio, has purchased the garage and sales agency of Hoyes & Moyer for a consideration of $50,000. The concern will have the Buick agency. It is located on East Center Street.

Crow-Elkhart Sales Co., Milwaukee, Wis., has been organized to take the Wisconsin and Upper Michigan distribution of the Crow-Elkhart line.

Frank Hanrahan has become state representative in Iowa for the Champion Ignition Co., Flint, Mich.

Auto Tire and Rubber Co., Seattle, Wash., has taken the agency in Western Washington for the Johnson shock absorber.

Mack & Saurer Truck Co. of Missouri, St. Louis, has been organized to handle the trucks named. Negotiations are under way for salesrooms and service station quarters. These trucks were sold by George C. Brinkman Motor Car Co., which recently closed up its affairs.

Kunkle Wagon Works, Baltimore, has taken the agency for the Interstate cars.

Homewood Motor Co., Baltimore, will handle the Abbott-Detroit.

Walbeck Tire & Rubber Co., Louisville, Ky., agent for the Racine tire, has moved into its new building at 305 East Broadway.

Metcalf-Ericson Motors Co., Louisville, Ky., agent for the Empire and Regal, has been appointed state distributor for the Stearns-Knight.

Stahl Automobile Co., Kenosha, Wis., has become a Buick dealer as successor to the agency held for several years by F. A. Rice.

Hallstead Messersmith Co., 310 Michigan Avenue, Buffalo, N. Y., has taken on the King line for Buffalo and vicinity.

S. E. Barnwell, who handles the King line in Louisville, Ky., has moved into new quarters at 813 Third Avenue.

W. C. Wampler Co., King distributor for Dayton, Ohio, has opened up new showrooms and service station at 132 North St. Clair Street.

Times Square Auto Supply Co. has established a western distributing store in Dallas, Texas.

Bearings Service Co., Detroit, has established headquarters at Dallas, Texas, for the Southwest. This is the selling company for the Hyatt Roller Bearing Co., the Timken Roller Bearing Co. and the New Departure Ball Bearing Co. Headquarters are in the new Masonic Building, Main and Pearl Streets.

The Southern Auto & Electric Co., Little Rock, Ark., will handle the Liberty car for the state.

J. V. Le Blanc, Jr., New Orleans, will become distributer of the Jordan. Mr. Le Blanc is a sugar grower at Thibodaux, La., where he sold cars at retail, and recently removed to this city

Val Rolle Wagon & Automobile Co., New Orleans, has entered the field as builders of commercial bodies for Ford chassis.

Burke-Court Motor Co., Memphis, Tenn., has been named distributer for Chevrolet.

Dixie Motor Sales Co., Memphis, Tenn., has succeeded the Franklin Motor Sales Co. and will handle Franklin, Crow-Elkhart and Cole 8 and Gramm-Bernstein trucks.

Shartenburg & Robinson, a New Haven, Conn., department store, has taken on the agency for the Jordan car and a model has been placed on exhibition on the main floor of the store.

Todd Rubber Co. has established a branch in Bridgeport, Conn., and in addition to handling Kelly-Springfield tires will stock accessories. C. E. Minnerly is manager. The concern has branches in New Haven, Ansonia, Danbury, Hartford, New London and Waterbury in addition.

McQuay-Norris Mfg. Co., St. Louis, has made a number of changes in its representatives. L. H. Dally has succeeded H. G. Paro as Chicago manager and the Chicago office has been moved to 1140 S. Michigan Boulevard. Dally has been chief of the McQuay-Norris field force of engineers up to the present. H. W. Sweeney has succeeded J. W. McKeen as manager of the Pittsburgh branch office. R. W. Long has been transferred from the field force of engineers to be manager of the Denver branch. He succeeds H. W. Sweeney.

New Orleans branch of the Goodyear Tire & Rubber Co. is installed in new quarters at 818-20 Howard Avenue.

A. Meyers' Sons Co., Richmond, Va., for many years prominent in the wagon and carriage trade, has been appointed Ford agent. This firm also operates an accessory store at 325 West Broad Street.

Sterrett & Fleming, Washington and Baltimore, has opened a branch in Richmond to show Detroit electric cars and Philadelphia grid batteries.

Arkansas Reo Co., Little Rock, Ark., has been named state agent for the Scripps-Booth.

Patterson Harness Co., Little Rock, Ark., has obtained the state agency for the American tires.

Auto Tire Co., Hartford, Conn., has taken on the Faure tire.

John Millen & Son, Ltd., Montreal, Que., has been appointed distributer for the Boyce Moto-Meter.

P. C. Meredith, Des Moines, state distributor for Bull tractors, has taken the agency for the Dort, and will also distribute the Hercules truck. The new firm is called the Meredith Motor Car Co.

R. W. Llewellyn has been appointed manager of the Columbus, Ohio, branch of the Kelly-Springfield Tire Co.

O'Rourke-Muller Motor Co., New Orleans, has secured the agency for the Elcar and the Ames Ford attachments. A salesroom and service station will be opened at 824 Barronne Street. Temporary offices are at 853 Carondelet Street.

George A. Loque, Jr., New Orleans, distributer of the Hal cars, has opened a salesroom at 640 Barronne Street.

Goodyear Rubber & Tire Co., St. Louis branch, has moved into its new quarters at 3010 and 3012 Locust Street.

National Motor Co., Denver, National, Elgin and Wescott distributer for Colorado and Wyoming, with headquarters at 1616 Broadway, has dropped the Wescott and is now handling only the other two lines.

Northwest Mercantile Co., Kremmling, Col., has secured the Dodge and Velie agency for Grand, Summit and Eagle counties.

Wm. Thorney Auto Co., Denver, Apperson and Regal distributer for Colorado and Wyoming, with headquarters at 1315 Broadway, has gone out of the selling business and expects to start a garage as soon as a suitable location can be secured.

Estabrook-McGraw Tire Co., Denver, is a new tire-distributing agency for Colorado and extensive adjacent territory in the Rocky Mountain region for McGraw tires, with headquarters at 1646 Broadway. The new firm is headed by G. H. Estabrook, Hollier and Briscoe distributer and proprietor of the Estarado Garage.

The King Motors Co. has leased the premises at 2813 Locust Street, St. Louis, Mo., vacated by the Brinkman Motor Car Co., for a factory branch. William Schreiber, who has been connected with Paige, Premier and other distributing agencies here, will be manager. A service station carrying a complete set of parts will be opened in charge of a factory expert.

Nichoalds Co., Detroit, for many years dealer in automobile parts and accessories, has entered extensively into the jobbing business.

Kaehler Motor Car Co., Richmond, Va., has started a fall competition in sales by offering a free trip to the New York automobile show to the employe making the best showing between Nov. 1 and the date of the show.

No Profitless Days with Stewart Products

Dealers sell Stewart Products every day, every week, every month in the year.

Each season is a Stewart Products season. That is one reason why Stewart Products are such a fast-selling and profitable line for dealers.

Stewart Products have a big sale in Winter, Spring, Summer and Fall—they are needed and used all the year 'round.

There is the Stewart Tire Pump, needed in the Summer, but an absolute necessity in Winter. When ice and snow cover the ground—when it is bitterly cold—there is no task so unpleasant as to get out and hand-pump a tire. A Stewart Tire Pump will do the work quickly while the motorist sits in the car, out of the cold. It's easy to imagine the comfort and convenience a Stewart Tire Pump gives.

The same is true of all Stewart Products—each one is a Winter necessity.

"It will pay you to see that every car is equipped Stewart."

Ajax to Purchase Racine Co.

Will Ratify Deal on Dec. 26—Ajax Increases Capital to $10,000,000

New York, Dec. 12—The Ajax Rubber Co., Inc., of tbis city and witb a factory in Trenton, N. J., has arranged for the purchase of tbe Racine Rubber Co., Racine, Wis., and bas called a meeting of its stockbolders for Tuesday, Dec. 26, at wbich the purchase of the Racine Co. will be ratified. It is understood that tbis purchase will not cbange tbe present status of tbe Racine Co., wbicb manufactures Racine and Horsesboe brand tires. The purcbase of the Racine company is in exchange for sbares of tbe captital stock of the Ajax organization.

New Capitalization

As a part of this purchase the Ajax company bas increased its capital stock from $5,000,000 to $10,000,000. Up to tbe present tbere bas been 100,000 shares of capital stock with a par value of $50, but under the new arrangement there will be 200,000 shares at the same par value. Tbe entire stock is common and there are no bonds. As a result of tbe deal and the rumors of it Ajax stock rose on the New York Stock Exchange from $70 to $90 in the past 10 days. Tbe company bas been paying 10 per cent dividends.

Rapid Development

During the past year Ajax has developed very rapidly, increasing its daily output from 2000 casings to 5000. There bas been a similar increase in the manufacture of tubes. During the year a new factory building, 550 by 350 ft. and tbree stories in height, has been occupied. In addition other warehouses have been built. During the year the number of dealers handling Ajax tires has been increased from 4000 to 6000. In addition seven new branch houses bave been opened, bringing the total to 23.

The Racine Rubber Co. has sold its output to approximately fifty to sixty jobbing accounts in contrast with the Ajax distribution through 6000 dealers. In tbis respect the lines complement each other and the present policy of distributing tbe Racine product through jobbers will be continued. The volume of business of the two concerns is approximately tbe same.

—

Cadillac Prices $160 Higher

Detroit, Dec. 11—The Cadillac Motor Car Co. will raise prices on all models $160, effective midnight Dec. 14. All cars shipped after tbat time will be charged at the new prices witb the following exceptions subject to prior sale. It will furnish at present prices cars of each body style to customers' signed unfilled contracts in tbe possession of the dealers on Dec. 14.

Increase Mack Truck Prices

New York, Dec. 8—The International Motor Co., this city, will advance its list prices on the Mack truck Jan. 1, as follows: 1-ton, $2,000 to $2,150; 1½-ton, $2,350 to $2,500; 2-ton, $2,700 to $2,800; 3½-ton, $3,400 to $3,650; 5½-ton, $4,000 to $4,250, and 7½-ton, $4,500 to $4,600.

—

Austin Increases Prices

Grand Rapids, Mich., Dec. 11—Tbe Austin Automobile Co., has increased the prices on its different 1917 models as follows: The two and four-passenger roadster from $3,150 to $3,750; the five- and six-passenger touring car from $3,400 to $3,750, and the seven-passenger touring car from $3,400 to $3,750; the coupé from $3,950 to $4,550; tbe sedan from $4,350 to $4,950, and the limousine from $4,650 to $5,250.

Analyzes After-War Conditions

Report of Federal Trade Commission Manifests Confidence for Future

Washington, Dec. 12—What will trade conditions be after the war is one subject handled in the long-looked-for recommendations from the Federal Trade Commission which deal with problems that will confront the United States, especially exporters, when bostility ceases. This report is a comprehensive review covering years of foreign trade conditions.

With regard to meeting European trade, the three important considerations involved are:

First—The presence of concerted action among the foreign competitors of American exporters.

Second—The probable effect of similar action by American manufacturers in foreign trade, including its possible disadvantages to domestic consumers and smaller competitors.

Third—The effect of the present laws of this country upon such co-operation on the part of American manufacturers.

Co-operation Advantageous

"The commission believes," says the report, "that the advantages to be gained by effective co-operation in foreign markets need not entail any sacrifice of the firmly established policy of this country in regard to the maintenance of fair competitive conditions and the prohibition of monopolistic control within the United States. At the same time, co-operation for export trade will enable the exporting manufacturer to realize an increased return for his products along with decreased costs through larger scale production, and the country

Newby Resigns from National

Had Directed Company's Affairs for 16 Years—Dickson Succeeds Him

INDIANAPOLIS, Dec. 10—Arthur C. Newby, founder and for 16 years president of the National Motor Car and Vehicle Corp., has relinquished the presidency of the company to his chief assistant and general manager, G. M. Dickson. Mr. Newby has not been in the best of health lately and his retirement has been expected. He continues, however, to be the largest individual National stockholder.

A pioneer in the automobile field, having been with the National Electric Car Co., back in 1888, and 2 years later forming the National Gasoline Engine company, he has naturally been an enthusiast in the industry's activities. He was a leader in the early days of racing, being a staunch advocate of stock car racing. His cars were usually among the leaders, if not winning.

Recent connection made with the substantial new interests in the affairs of the National company, were the means of greatly increasing the size and production of the factory. With the company on the enlarged basis Mr. Newby proposed that Mr. Dickson be made president.

Mr. Dickson is not a newcomer to the automobile field, being associated with Mr. Newby at the National plant for 15 years.

With the change of titles the new officers are the same individuals who have assisted in the management of the factory for the past 10 years. They are: G. M. Dickson, president and general manager; W. Guy Wall, vice-president and chief engineer; and M. E. Elstum, secretary and treasurer.

—

Precision Die Casting Merges Two Companies

SYRACUSE, N. Y., Dec. 9—The entire business of the Van Wagner Die Casting Corp., formerly the E. B. Van Wagner Mfg. Co., and the Precision Die Casting Co. has been purchased from Charles Van Wagner and the two companies will be merged into the Precision Die Casting Co., with a capital of $315,000.

Alterations and extensions to the factories have already been undertaken and more capital provided to take care of increased business.

The officers and directors of the new company include: President, T. G. Meachem, vice-president and general manager of the New Process Gear Corp.; vice-president, J. W. Knapp, treasurer of the Van Wagner Die Carting Corp.; treasurer, H. S. Tenney, secretary of the Syracuse Trust Co., and secretary, E. J. Quintal, of the accounting firm of Farrell, Sehl & Quintal. The above officers and the following include the directors: A. P. Bellinger, of the Solvay Process Co.; G. W. Bowen, of the G. W. Bowen Mfg. Co., Auburn, N. Y., and W. A. Ball, of the Semet Solvay Co.

Gauvreau Joins Buick

DETROIT, Dec. 9—Victor Gauvreau has resigned as chief engineer of the Frontenac Motor Co. to join the Buick Motor Co., Flint, Mich.

—

Weed Chain Maker Plans Capital Increase of $6,000,000

NEW YORK, Dec. 13—Stockholders of the American Chain Co., maker of the Weed chains, have been notified that a meeting will be held on Dec. 22 for the purpose of voting on an increase of capital from $4,000,000 to $10,000,000 by increasing the preferred from 20,000 shares, par $100, to 50,000 shares, par $100, and by increasing the common from 20,000 shares, par $100, to 50,000 shares, par $100. Each share of additional preferred will be entitled to the same preference and priority over the common as the preferred now issued and outstanding.

—

American Chain Takes Standard

YORK, Pa., Dec. 12.—The Standard Chain Co., operating nine large plants throughout the country, passed into the hands of the American Chain Co., with the sale of its interests to the latter and the resignation of J. C. Schmidt, York, Pa., the president of the Standard Chain Co. for the past 17 years, this week. The products of the Standard company include at least 1500 varieties, sizes, styles and types of chain, with automobile chain and automobile forgings.

Besides the two plants in York the company had been operating chain plants at Braddock, Allegheny county; rolling mill and Hayden chain plant at Columbus, O.; and one plant in each of the following cities: Carlisle, Pa., Mansfield and St. Mary's, Ohio, and Marion, Ind. The company employs approximately 1700 hands, of these 1000 being employed in the two York plants.

Arthur C. Newby, founder and president of the National company for the last 16 years

Bans Newspaper Publicity

P. O. Points Out It Violates Rule Against Advertising as News Matter

WASHINGTON, D. C., Dec. 12—Automobile publicity which has been carried in daily papers has come under the finger of the third assistant postmaster general, who has notified several daily papers that this publicity is in violation of the act of Aug. 24, 1912, which forbids the running of statements which are properly advertising matter and not news. Large daily papers in many cities have received letters from the third assistant postmaster general drawing attention specifically to items published which are properly advertising information. The department expects to report later on the result of its investigations. The article in question appearing in the daily papers cover a variety of subjects, some refer to the opening of new agencies, others to the photographs of new cars, others to comments on winning contests and others on various subjects. The presumption is that many daily papers have been accepting reading notices from concerns placing advertising, it being stated that the reading notice is a verbal part of the advertising agreement. This situation has come to the attention of the third assistant postmaster general with the results as stated.

There are various suggestions as to how the matter reached official circles in Washington. It has been stated that paper manufacturers displeased with the complaints of publishers have intimated that if the daily press cut out the free readers there would be room for plenty of news that is at present kept out. Those large daily papers which have strongly and consistently opposed this method of publicity are naturally gratified at the present investigation.

In a Friendly Spirit

Third Assistant Postmaster General, W. M. Dockery, discussing with a representative of THE AUTOMOBILE the movement, said he was taking this step in the friendliest possible spirit as toward the newspapers of the country, and he felt and believed it would be only necessary for him to call the attention of publishers to the law which forbids such a practice, to bring about a cessation of this form of activity.

"While it is hard to draw the line of demarcation between a newspaper article discussing certain facts in connection with the performance of a suggested make of an automobile, which article might not constitute an advertisement,

To Facilitate Argentine Shipments

Mercantile Corp. Formed for Co-operative Trade in Non-Competing Lines

NEW YORK, Dec. 13—The Argentine Mercantile Corp., an organization for the purpose of co-operative trade in non-competing lines, has been started in this city for the purpose of making trade with Argentina easier to handle. Fifty to sixty different U. S. A. manufacturers in varied lines, none connected with the automobile industry, are reported to have met last week for preliminary organization work and will meet later this week to complete organization plans and elect officers.

The plan of this corporation consists in maintaining in the city of Buenos Aires a permanent exhibition of samples of all goods manufactured by those who are members of the corporation. This exhibit of samples will be in charge of salesmen and in addition there will be a force of salesmen traveling through the Argentine Republic in the interest of those belonging to the corporation.

To facilitate shipping of goods, exchange, collections, etc., the Argentine Mercantile Corp. contemplates maintaining a shipping department at the Bush Terminal, New York City, where 3700 sq. ft. of shipping space will be maintained and a clerical shipping force engaged. It will only be necessary for members to consign their merchandise to this office, after which all matters of crating, engaging accommodation, marine insurance, etc., will be handled by the corporation.

In the matter of payments, it is expected that members will be paid for their merchandise when delivered at the Bush Terminal and that the corporation will handle the entire work of collections in South America, banking accommodations, exchange, etc.

According to the present plans, which are very incomplete, each member of the corporation will place samples in the Buenos Aires exhibit, and that the rent for such exhibit building, overhead, and other charges will be paid for by the members according to the exhibit space they occupy. It is planned to place one salesman over each particular line of merchandise, such as agricultural machinery, or automobile accessories, or hardware lines, etc. Only one make of automobile or one make of motor truck would be handled.

The organization of the Argentine Mercantile Corp. has not progressed sufficiently to state what membership initiation fees, and annual dues will be charged. The corporation has been organized for the purpose of profit and dividends will be declared in some manner to those participating. It is expected that manufacturers will sell goods to the corporation at their export prices. It is planned to place the organization in the control of thirty-one directors, fifteen of whom have already been named.

The organization is being fostered by one William Hill Hunt. Mr. Hunt says he has spent some time during the past year in Argentina collecting information on those lines of goods which have sold best in the republic.

Joy Leaves Packard — Dividend Increase

DETROIT, Dec. 14—H. B. Joy has resigned as chairman of the board of directors of the Packard Motor Car Co. because of other interests. At its meeting here yesterday the board of directors increased the dividend on the stock from 7 to 8 per cent yearly payable as 2 per cent quarterly. The next payment is January.

—

Pfeffer and Brinegar Go to Cuba

DETROIT, Dec. 12—C. A. Pfeffer, who recently resigned as vice-president and assistant general manager of the Chalmers Motor Corp., and E. P. Brinegar, the man credited largely for the organization of the old E. R. Thomas Detroit Co., sailed from New York City last Saturday for a pleasure trip through Cuba.

—

Holmes Building Own Car

SYRACUSE, N. Y., Dec. 12—Arthur Holmes, formerly sales manager of the H. H. Franklin Mfg. Co., this city, has started a company of his own in this city for the purpose of manufacturing automobiles.

—

Chalmers to Retire from D. A. C. Presidency

DETROIT, Dec. 8—Hugh Chalmers has announced that he will retire permanently from the presidency of the Detroit Athletic Club, of which he has been the head for the past four terms. Coupled with his announcement Mr. Chalmers has presented the club with Herman Richir's painting "The Red Shawl," which he acquired following its exhibition in the Belgian section of the Panama-Pacific Exposition.

Mr. Chalmers has been the only president the club has had since moving to its downtown location.

—

Ball & Ball Carbureter on Winton

CLEVELAND, OHIO, Dec. 6—The Winton Co. has adopted the Ball & Ball carbureter, made by the Penberthy Injector Co., as standard equipment.

To Raise Tire Prices 15 to 20%

Increase in Price of Materials and Cost of Manufacture Responsible

NEW YORK, Dec. 9—Leading tire manufacturers are planning to make a substantial advance in automobile tire prices next year. This increase, it is expected, will be between 15 and 20 per cent. Early this year prices were advanced an average of 12½ per cent.

The high cost of the materials used in the manufacture of tires has necessitated this increase. Fabric is now selling at an advance of about 125 per cent over the figure of a year ago. Although crude rubber is not now commanding exorbitant prices, other materials used in tire making are advancing skyward and there is a greater amount of fabric than of rubber in an automobile tire. On an average, the cost of the materials used in tires has risen at least 20 per cent.

—

Lansdale Leaves Denby Truck

DETROIT, Dec. 11 —Henry Lansdale has resigned the vice-presidency of the Denby Motor Truck Co. Mr. Lansdale has been the vice-president and general manager for the company since 1915.

—

Girl Heads Standard Parts

CLEVELAND, Dec. 8—Christian Girl is president of the Standard Motor Parts Co., the combination of the Standard Welding Co. and the Perfection Spring Co. The Perfection plant will now be known as the spring department and the Stanweld plant as the rim and tube department.

Other officers of the new concern are: F. W. Prentiss, first vice-president; E. W. Farr, second vice-president; T. E. Borton, treasurer. C. C. Bolton and Arnold S. Goss, together with the officers above, will constitute the board of directors. P. A. Connolly is secretary, but not a director.

—

Jackson Goes to Europe

DETROIT, Dec. 11 —R. B. Jackson, factory manager for the Olds Motor Works, has gone to Europe to study automobile construction. He will visit London, Paris, Germany and Italy, and will attend the automobile show at Paris besides visiting all factories.

—

Bethlehem Truck Ready in February

NEW YORK, Dec. 12—Two truck models of 1¼ and 2 tons' capacity will be marketed about February by the Bethlehem Motors Corp., Allentown, Pa. A new

plant to have a floorspace of 199,000 sq. ft. is being built. The concern has a capital of $6,000,000, made up of $1,000,000 preferred, paid in, and $5,000,000 common. The preferred is all held by the four men who head the concern.

Arthur T. Murray, formerly of the Brady-Murray Motors Corp., local Chandler dealer, heads the concern as president. Associated, besides Allentown and Bethlehem capitalists, with Mr. Murray is W. S. Stevenson, formerly sales manager of the old Mack Bros. Motor Truck Co., who will be sales manager. D. G. Dery, a silk manufacturer, is vice-president.

—

Carburetion Subject of Ind. S. A. E. Meeting

INDIANAPOLIS, IND., Dec. 9—The December meeting of the Indiana Section of the Society of Automobile Engineers will be held Dec. 15 in the Assembly Hall of the Claypool Hotel.

The subject of the meeting will be "Carburetion and Manifolding," papers being read by F. C. Mock, chief engineer of the Stromberg Motor Devices Co., and by Professor Berry, professor of experimental engineering, Purdue University.

—

582 S. A. E. Banquet Tickets Sold

NEW YORK, Dec. 7—Tickets for the annual banquet of the Society of Automobile Engineers on Jan. 11 at the Hotel Biltmore are being sold fast. To date 582 have been sold out of a total of 750. Every seat, numbering 762, has been taken for the special performance of Ziegfeld's Midnight Follies, which comes as a climax to the dinner.

—

S. A. E. to Meet in Detroit

DETROIT, Dec. 11—The Engine and Transmission Division of the Society of Automobile Engineers, and of the Council of the S. A. E. will meet in Detroit on Dec. 14.

—

Stetson Motor Car Co. Formed

DOVER, DEL., Dec. 7—The Stetson Motor Car Co., with a capital of $1,000,000, has been incorporated to manufacture automobiles and appliances. The incorporators are P. A. Zizelman, W. Hanford and C. W. Van Ranst, all of New York.

—

Troy Trailer Sales Co. Formed

TROY, OHIO, Dec. 11—The Troy Trailer Sales Co. has been incorporated under the laws of Ohio by C. A. Geiger, C. N. Peters, G. R. Harris, R. C. Sykes and H. H. Tamplin. The Troy Wagon Works Co. will henceforth market its trailers under the name of the Troy Trailer Sales Co.

New Engine-Testing Method

Prof. Roesch, of Armour Institute, Describes His System Before Mid-West S.A.E.

CHICAGO, Dec. 9—A method of testing automobile engines and of charting the results of these tests in such a manner that a great deal more information becomes available than has been possible in present methods of testing has been developed by Prof. Daniel Roesch, associate professor of gas engineering Armour Institute of Technology. It is Prof. Roesch's contention that the present method shows the performance only under wide-open throttle conditions, a condition not often maintained in use, and that one engine showing superior merits to another under the usual test conditions might not be so good when tested under properly open-throttle conditions, at which most automobile engines are usually operated. His method involves, of course, tests made in the conventional way at various speeds with wide-open throttle and corresponding one at other throttle positions, thus giving power, gasoline consumption, heat losses, effect of spark advance, etc., under all conditions as driving. Prof. Roesch explained his method of conducting tests and outlined the results obtained and what was to be deduced from them in his paper presented at the quarterly meeting of the Mid-West section last night. This meeting was held at the Armour Institute of Technology, Chicago, and after the presentation of the paper and its discussion the speaker conducted the seventy-five engineers and motorists present to the testing laboratory of the institution and actually ran a partial test, according to his new method, on a twelve-cylinder Packard engine.

In the discussion G. A. Smith, of the Nash Motors Co., brought out the fact that the results of Roesch's tests showed the great advantage from economy standpoint of operating the engine at a certain definite speed and that it was one of the reasons for the better economy of European engines that more gear changing was done.

In reply to his question whether all the curves shown were the result of tests and whether all were made on the same carbureter setting, Mr. Roesch explained that the carbureter setting must he maintained constant.

Engineer Mock, of the Stromberg company, suggested that Roesch's method of testing could be used to co-ordinate curves of engine and car performance by using the deceleration test for car performance, and that he had witnessed car tests on the road which showed the practical value of Roesch's charts. He pointed out that chart No. 7 showed the economy of gearing the car low. He said he had witnessed an increase in economy of from 18 miles per gallon to 30 m.p.g. by gearing the car as a truck is geared and shifting as necessary. He felt the spark advance should be susceptible to control according to the throttle opening.

—

Buffalo Section S. A. E. Formed

BUFFALO, Dec. 13—*Special to* THE AUTOMOBILE—The Buffalo section of the Society of Automobile Engineers was enthusiastically formed here to-night at the Buffalo Engineering Society meeting, 150 being in attendance. The governing committee of the new section is: Chairman, David Fergusson, chief engineer pleasure car department Pierce-Arrow Motor Car Corp.; vice-chairman, C. M. Manly, vice-president and chief engineer Manly Drive Co.; secretary, D. W. Sowers, president and engineer Sowers Mfg. Co.; treasurer, John Younger, chief engineer motor truck department Pierce-Arrow Motor Car Corp. and chairman of membership committee, H. T. Parrock, manager Lumen Bearing Co.

Russell Huff, president of the S. A. E., Coker Clarkson, secretary and general manager, and A. Ludlow Clayden, chairman of the standards committee, spoke on the general advantages of the society, President Huff stating that within 4 weeks the society will have a membership of 2600, the Detroit section now having over 650.

The paper by A. P. Brush on the four-cylinder engine, appearing on pages 1006 and 1007 of this issue, provoked considerable discussion, seeming to fall in with the views of those present.

—

Re-organization of Ross

DETROIT, Dec. 12—It is reported that C. G. McCutcheon will resign his presidency of the Ross Automobile Co. to take effect Jan. 1, and that a number of New York capitalists will re-finance the concern to the extent of $500,000.

—

Muir Heads Maxwell Advertising

DETROIT, Dec. 12—Gordon Muir has been appointed advertising manager of the Maxwell Motor Co., Inc. Mr. Muir has been with the Maxwell company for the past year.

—

Weed Hal Advertising Manager

DETROIT, Dec. 11—J. C. Weed has been appointed advertising manager of the Hal Motor Car Co. of Cleveland.

—

Lloyd Is Cassidy Advertising Manager

NEW YORK, Dec. 11—L. M. Lloyd has become advertising manager for the Edward A. Cassidy Co., this city. The Cassidy company handles the national sales of many automobile accessories.

Makers Arrange Banquet Program

White Toastmaster—Speakers Include Leland, Coffin and Clarkson

DETROIT, Dec. 12—A reception committee has arranged a program for the Manufacturers' Banquet to be given by the Society of Automobile Engineers on Dec. 14. The committee is composed of D. McCall White, chairman, and chief engineer of the Cadillac Motor Car Co.; B. G. Koether, general sales manager of the Hyatt Roller Bearing Co.; Russell Huff, chief engineer for Dodge Bros.; W. C. Rands, president of the Motor Products Corp.; K. W. Zimmerschied, chief metallurgist for the General Motors Co.; R. F. Dyer of the Aluminum Castings Co.; J. E. Diamond, engineer for the Aluminum Castings Co.; A. H. Doolittle, sales and advertising manager of the Zenith Carburetor Co.; W. B. Stout, manager the aircraft department of the Packard Motor Car Co.; A. I. Stevens of the N. Z. Graves Corp.; C. L. Nedoma of the Chalmers Motor Co.; L. V. Spencer of E. E. McCrone & Co.; L. B. Fijux, branch manager of the Bijur Motor Lighting Co.; H. A. Brown, sales engineer of the Hyatt Roller Bearing Co.; R. T. Middletown, branch manager for the Steel Products Co.; W. C. Keys, assistant engineer of the Cadillac Motor Car Co.; C. T. Myers, consulting engineer, and O. E. Hunt, chief engineer the carriage division of the Packard Motor Car Co.

The program will be started by a speech from Russell Huff, president of the Society, who will introduce D. McCall White, who will be toastmaster for the occasion. Other speakers will include Coker F. Clarkson, general manager of the S. A. E.; Job Hedges of New York; Captain L. E. Goodier, Jr., of the aviation service; H. M. Leland, president of the Cadillac Motor Car Co., and Howard Coffin, director of the Hudson Motor Co., besides a number of others who are expected to signify their assent shortly.

—

Lozier Brothers Co. Announces New Cars and Officers

PHILADELPHIA, Dec. 11—The Lozier Brothers Co., recently formed with a $1,000,000 capital to build a four at $785 and a six at $1,595, announces its officers and directors as follows: H. A. Lozier, president; G. P. Grandfield, vice-president, former first assistant United States postmaster general; H. S. Evans, treasurer, manager of the International Time Recording Co., Philadelphia; P. E. Remington of New York; H. C. Shober, vice-president of the National Bank of Huron, S. D.; F. M. Byrne, Governor of South Dakota; Roswell Davis, president of the First National Bank, Freeport, L. I., N. Y.; Hugh Herndon, New York lawyer; Kern Dodge, consulting engineer, Philadelphia, and a director in the Link-Belt Co., Chicago, and James Levy, Chicago. The four-cylinder car will be featured with a 3⅜ by 5¼ valve-in-head engine, Stromberg carbureter, Remy distributer, thermo-syphon cooling, semi-elliptic springs, 32 by 3½-in. tires, and a 112-in. wheelbase. The six-cylinder model will have a 3½ by 5½ valve-in-head engine, Bosch magneto, 34 by 4½-in. tires, and a 127-in. wheelbase.

—

General Engineering Directorate Completed

DETROIT, Dec. 8—At a meeting of the stockholders of the General Engineering Co., this week, the organization of the directorate was completed. The members of the board include Abner Doble, J. H. French, M. J. Hammers, C. L. Lewis, A. W. Russel and W. F. Trant. Officers elected were C. L. Lewis, president; Abner Doble, vice-president, and M. J. Hammers, secretary and treasurer.

—

Bucyrus Rubber Elects Directors

BUCYRUS, OHIO, Dec. 7—The following directors were elected at the annual meeting of the Bucyrus Rubber Co., this city: W. A. Blicke, Jacob Coulter, P. H. Heater, Philip Browarsky, A. J. Richards, W. J. Schwenck, A. G. Stoltz, H. A. Paxton and George Donnenwirth.

The company is at present employing forty-five men with a daily output of eighty tires.

—

$10,000,000 Parts Co. Plans Industrial Town in Los Angeles

LOS ANGELES, Dec. 13—A $10,000,000 parts concern, under the name of the Eisenhuth Motor Co., has been formed and has obtained an option on a 364-acre site at Los Angeles harbor. It proposes erecting a parts and assembly plant, a foundry and factory buildings to construct parts for all makes of automobiles and trucks. It will build everything that enters into automobiles except tires.

J. W. Eisenhuth, president of the company, is a capitalist, formerly of New York and Brooklyn. He states that the project is being financed by eastern capital. Eisenhuth's idea is to surround the factories with an industrial town where living conditions are ideal. He says construction will start next month.

—

Monroe Buys Four-Story Factory

PONTIAC, MICH., Dec. 13—The Monroe Motor Co. has purchased the four-story factory formerly owned by the Auto Painting & Trimming Co. This acquisition increases the Monroe company's available floorspace by 100,000 sq. ft.

113,000 Overlands on Contract

Valued at $100,000,000—More Than 4600 Dealers Attend Convention

TOLEDO, Dec. 13—During Monday and Tuesday of this week 29,500 cars valued at $25,000,000 were signed for by Willys-Overland dealers in convention at the factory. This makes a total of 113,000 cars worth $100,000,000 taken by dealers since the opening of the convention, Dec. 4. Over 4600 delegates have arrived at the factory.

The convention will continue until Dec. 23, with fresh groups arriving every other day, and John N. Willys, president of the company, believes that the 3 weeks during which the dealers will be in Toledo will mark the sale of 200,000 cars, with a value of $200,000,000, which means that the company's entire output for 1917 will have been contracted for.

The company is doing everything in its power to make the convention a success from both an industrial and entertaining viewpoint.

—

Willys-Overland Increases Wages

TOLEDO, Dec. 9—Wages of the employes of the Willys-Overland Co., will be increased to total $1,250,000 per year. The wages of companies allied with the Overland company have been increased $225,000 per year at the Electric Auto-Lite Co., $350,000 per year at the Morrow Mfg. Co., of Elmira and $100,000 per year at the Morrow Mfg. Co. at Elyria, Ohio. The rates of increase are:

All rates up to and including 30 cents per hr. will be increased 10 per cent.

All rates over 30 cents and including 40 cents per hr. will be increased 7½ per cent.

All rates over 40 cents per hr. will be increased 5 per cent.

All piece work rates will be increased 5 per cent.

—

A. O. Smith Raises Wages 10%

MILWAUKEE, Dec. 13—The A. O. Smith Co., this city, has announced a 10 per cent increase in wages for all employees drawing less than $125 per month, effective Dec. 1. This affects approximately 1400 men.

—

Heinze Concentrates on Ford Starters

SPRINGFIELD, OHIO, Dec. 12—The John O. Heinze Co., manufacturer of starting and lighting apparatus, is at present confining its entire efforts to the manufacture of Ford starters. The factory has a daily capacity of 100 outfits and

has 280 employees. The company is manufacturing all of the electrical apparatus entering into these, such as manufacturing its own armatures, doing its own winding, and manufacturing its fixtures and regulators. The company incorporated in July a year ago and started production in March of the present year. It was not until last October that the present rate of production was reached.

—

Smith Truck Elects Directors

NEW YORK, Dec. 7—The Smith Motor Truck Corp. at its directors' meeting elected the following board of directors: A. D. Smith, E. I. Rosenfeld, A. G. Hanauer, J. M. Hoyt, C. B. Little and Louis Hennock.

—

Clodio to Concentrate on Houdaille Shock Absorber

NEW YORK, Dec. 12—Paul V. Clodio, until recently senior partner of the firm of Clodio & Engs, metropolitan distributor for Kissel, has resigned from that firm to form the Houdaille Shock Absorber Co., Inc., at 1737 Broadway, New York. Associated with Mr. Clodio as incorporators are John N. Van Vranken and Edwin Rushmore.

The plan is to exploit more widely the Houdaille patents and Mr. Clodio has found it desirable to confine his efforts more closely to the shock absorber, the American rights to the manufacture of which he has controlled for years.

The Houdaille shock absorber is standard equipment on the Mercer cars for 1916 and 1917 and on the Peugeot, Panhard, Delaunay-Belleville and other prominent foreign cars.

—

Star Prepares to Make Tires

AKRON, O., Dec. 11—The Star Rubber Co. is preparing a plant with 100,000 feet of floorspace for extensive manufacturing of tires. The Star company, organized in 1910, has manufactured to a large extent rubber goods for druggists and surgeons, and in 1916 started manufacturing tires in a small way. The company has been recapitalized at $500,000.

L. H. Firey is president and treasurer. He was for 15 years proprietor of the Coates House in Kansas City. R. R. Robinson, vice-president, is vice-president of the Robinson Clay Products Co., Akron. O. L. Weaver, secretary, was for 10 years with Goodyear, 2 years with Willys-Overland, and the last 4 years northeastern Ohio Pierce-Arrow dealer.

Other prominent stockholders include H. B. Manton, president of the Robinson Clay Products Co.; Francis Sieberling, connected with several Akron rubber companies; I. R. Manton, a director of the Robinson Clay Products Co.; J. P. Loomis, president of the Akron Coal Co., and George D. Bates, vice-president of the First-Second National Bank of Akron.

To Confer on Aeronautics

—

M. & A. M. and N. A. C. C. Interested—Five New Accessory Members Elected

NEW YORK, Dec. 11—Realizing the important part that aeronautics are destined to play in the future and their close connection with the automobile accessory business, the forthcoming First Pan-American Aeronautic Exposition to be held in Grand Central Palace, New York, Feb. 8 to 15 inclusive, was discussed and acted upon by the executive committee of the M. & A. M. at its monthly meeting in New York, Dec. 8.

Following a talk by Howard E. Coffin, of the Hudson Motor Car Co., and chairman of the Pan-American Aeronautic Exposition, who thoroughly explained the objects of the aeronautical exhibition and aeronautics in general, it was voted to appoint a committee of three to confer with similar committees from the National Automobile Chamber of Commerce, the Aero Club of America, the Pan-American Aeronautic Federation and the American Society of Aeronautic Engineers, at which time the matter of officially approving the aeronautical show will be discussed. Those who will represent the M. & A. M. include President C. W. Stiger, C. E. Thompson, chairman of the show committee, and William M. Sweet, director.

During the past week the M. & A. M. has been elected to membership in the Chamber of Commerce of the United States of America and President C. W. Stiger was elected as national councillor and Vice-President C. E. Thompson as delegate to represent the accessory association in connection with the Chamber of Commerce.

William M. Sweet, chairman of the banquet committee of the M. & A. M., reported in connection with the forthcoming banquet to be held at the Waldorf-Astoria, Jan. 10, that the sale of tickets had greatly exceeded that of any previous year and that it was expected that the 1917 banquet would be the most successful in the history of the M. & A. M.

Five new members were elected, making a total membership of 263 manufacturers of motors, part and accessories.

The new members are: Automatic Carbureter Co., Chicago; Superior Lamp Mfg. Co., New York; Amalgamated Machinery Corporation, Chicago; Warner & Swasey Co., Cleveland, and the Metal Stamping Co., Long Island City.

Those present at the meeting were C. W. Stiger, president of the Stromberg Motor Devices Co., Chicago; C. E. Thompson, president of the Steel Products Co., Cleveland; E. H. Broadwell, vice-president of the Fisk Rubber Co., Chicopee Falls; Christian Girl, president of the Perfection Spring Co., Cleveland; W. O. Rutherford, general sales manager of the B. F. Goodrich Co., Akron; William M. Sweet, assistant to president of the United Motors Corp., New York; Sidney S. Meyers, counsel of the M. & A. M., and L. M. Bradley, manager.

—

Kearns Is Lee Tire Manager

CONSHOHOCKEN, PA., Dec. 8—John Kearns has become general manager of the Lee Rubber & Tire Co. He was the organizer of the British Dunlop Co. of Australia. Mr. Kearns comes from the Fisk Rubber Co., Chicopee Falls, Mass., where he was vice-president.

—

Jackson Is Briscoe Comptroller

JACKSON, MICH., Dec. 13—W. V. C. Jackson has been appointed comptroller of the Briscoe Motor Corp. Mr. Jackson was formerly general manager of the motor wheel division of the A. L. Smith Co.

—

Kellum with Columbia Motors

DETROIT, Dec. 8—E. F. Kellum has been appointed as purchasing agent for the Columbia Motors Co. Mr. Kellum was formerly associated with the Weston-Mott Co., of Flint. G. J. Martin has been appointed auditor for the Columbia company. Mr. Martin was formerly deputy city comptroller of South Bend, Ind.

—

Rahan To Make Ford Starters

DETROIT, MICH., Dec. 12—Electric starters will be made for Ford and other cars by the Rahan Co., which is incorporating Jan. 15 under the laws of Michigan for $100,000.

It is a 12-volt, two-unit system made in straight line form, the generator and motor shafts being co-axial. The patents under which the machine is being made are held by Frank B. Rae, and the principal one is No. 1,153,338 on a transmission mechanism. This is a missing tooth differential operated by a cone which at the apex end terminates in an offset ball connection to the driving shaft and at the base end carries upon its periphery a set of gear teeth, one less in number than the set with which it meshes on the driven side. The device as arranged on the standard unit gives a 30-1 reduction.

The starting motor is series wound and has an over-running ball clutch engagement. It gives 81.6 ft. lb. stalling torque, it is said, with a weight of 42 lb. It is largely made from stampings and die castings. It is regulated by magnetic control. The generator has a charging rate of from 7 to 15 amps., cutting in at 8 m.p.h. The outfit for Fords will sell for $50.

Tanks for U. S. Army

Will Have Two Revolving Turrets, Armored Machine Guns and Motorcycles

WASHINGTON, Dec. 11—Chief of Ordnance of the Army Crozier, in a report just made, declares that the United States Army soon will be equipped with caterpillar tractors similar to those in use in the British army, the so-called "tanks." The report of General Crozier says armored cars, with two revolving turrets, mounted with machine guns; armored machine guns, equipped motorcycles and individual armor for the men of the ranks, also are under consideration.

Along this line the quartermaster general of the army, in a report, shows that $2,175,000 was spent by the army on motor truck equipment alone after the expedition was ordered into Mexico in pursuit of Villa.

The quartermaster general, in testifying before the House military committee, said that the use of trucks for transportation purposes has more than tripled the mobility of troops. He added that had General Pershing only mule trams to use in moving his command he could not have traveled half the distance he did in Mexico.

Col. Chauncey Baker of the Quartermaster's Corps testified that a motor truck made from 60 to 120 miles a day against a possible maximum of eighteen for mule teams. A four-mule team, he added, would eat in 4 days all the fodder it could haul. It was shown by Colonel Baker that the army now has 2600 motor trucks of several satisfactory types, and that the machines show less than 20 per cent depreciation in efficiency, despite the severe tests imposed by the hard service they were put to.

Representative Julius Kahn told the committee he was told by Brig-Gen. Franklin J. Bell that it would be possible to put 50,000 men into Chihuahua City in 2 days by motor truck.

Indorse 42-In. Head-lamp Law

NEW YORK, Dec. 8—A conference on the head-lamp situation was held at the S. A. E. office here to-day, among those present being A. Reeves, National Automobile Chamber of Commerce; A. G. Batchelder, A. A. A.; Elmer Thompson, Automobile Club of America; C. A. Stewart, Motor Dealers' Association; A. Ludlow Clayden, chairman S. A. E. standards committee, and Alden McMurtrie, consulting engineer, who has made many experiments with automobile lighting. It was agreed that the limitation of head-lamp rays to rise not more than 42 in. above the road at a distance of 75 ft. or more in front of the car was a solution of the difficulty which was desirable. It is easy to make lamps which will conform to and to adjust existing lamps to suit a regulation of this sort. What is required is a much more general spreading of the knowledge of how to focus and set head-lamps. It was remarked that of all instruction books issued by automobile manufacturers, very few indeed gave any instructions for focusing a lamp, although this is almost as important as adjusting a brake. Thus it seems that the chief work of the different bodies representing automobilism will be to educate users of cars, dealers, repairmen and manufacturers into the art of lamp adjustment. The work now being done by the S. A. E. committee in an experimental way will benefit the manufacturer most of all by indicating how to make lamps in the future that will require a minimum of adjustment.

—

Win Temporary Injunction Against Ford

DETROIT, Dec. 9—A temporary injunction, restraining Henry Ford and the Ford Motor Co. from the erection of a $12,000,000 blast furnace plant was granted in behalf of John F. and Horace E. Dodge by the Wayne county circuit court in the decision rendered to-day in their suit against Henry Ford. The extensions to the Ford plant, now in process, are not affected by the decision. The judges recommended that the suit come to a hearing on its merits within 60 days.

The suit will come before the court again Dec. 13, when counsel for both sides will appear before Judg Wiest to arrange for carrying out the conclusions of the judges.

—

Two Ghent Models for 1917

CHICAGO, Dec. 13—The Ghent Motor Co., Ottawa, Ill., will bring out a four at $750 and an eight at $1,050 in 1917. Both models are touring cars. The four will use an L-head 3¾ by 4¼-in. motor, developing 37 b.hp. Oiling is accomplished by force feed and splash system. It also uses the model R Schebler carbureter with hot air stove and the electrical system is the three-unit Gray & Davis. A 6-volt starting and lighting and manual control ignition system with a 90-amp. hr. storage battery and a motor-driven horn are used. Rear axle is floating and the drive is Hotchkiss. Springs are semi-elliptic, both front and rear. The wheels are Parker hydraulic pressed steel. The body has the center cowl with straight stream line from radiator back. The windshield is set at an angle of 25 deg.

With the exception of the rear axle, which is three-quarter floating, the specifications of the eight are practically the same as the four.

Military Tractor Train Tested

U. S. Government Makes Exhaustive Test in Texas of Caterpillar Type

MARFA, TEX., Dec. 7—The initial test run of the military tractor train recently received here from Peoria, Ill., for use in the Big Bend region of the upper Rio Grande border, has just been finished. The run was made over a rough stretch of country, and is said to have come up to the army requirements in every way. The test was conducted under the direction of Capt. H. A. Hegeman, quartermaster in charge of the motor truck shops at Fort Sam Houston.

The run was made between Marfa and Presidio, a distance of 63 miles, over a desert, rough region where water is scarce. The equipment consisted of a 75-hp. caterpillar tractor and four trailers, each equipped with caterpillar tread instead of wheels. Each trailer had a cargo-carrying capacity of 15 tons.

The trip was made at an average speed of about 2½ m.p.h. over a road that is a road in name only. The train was loaded to full capacity with supplies on its outgoing trip. Captain Hegeman will make a complete report on the trial trip to Col. H. L. Rogers, chief quartermaster of the Southern Department, with headquarters at Fort Sam Houston.

—

Anderson Motor Co. Incorporates

ROCK HILL, S. C., Dec. 8—The Anderson Motor Co., this city, maker of the Anderson car, has incorporated with a capital of $1,500,000. The incorporators are J. B. Johnson, J. G. Anderson, T. L. Johnston, J. M. Cherry, Alex Long and J. W. O'Neal, all of this city, and J. A. Carr of Birmingham.

—

United Takes Over Fairbanks Hammers

BOSTON, Dec. 9—The United Hammer Co., this city, has purchased the power hammer business of the E. & T. Fairbanks & Co., St. Johnsbury, Vt., which marketed them under the name of Dupont. In 1902 the business was taken over by E. & T. Fairbanks & Co., which has been manufacturing them since.

—

Willis Is Hal Vice-President

DETROIT, Dec. 11—F. B. Willis, who recently resigned as sales manager for the Chalmers Motor Corp., has become the vice-president of the Hal Motor Co., of Cleveland. Mr. Willis will be in charge of the sales, service and advertising and in addition will be assistant to the president of the company.

South Is Buying More Cars

States There in Sound Financial Condition—Good Roads Promote Sales

ATLANTA, GA., Dec. 7—The South is buying more automobiles this year than in any time in its history. A comparison of automobiles shipped this year reveals an increase of nearly one-half over that of last year. The sounder financial condition of the Southern States is largely responsible for the increased shipments.

Twenty cent cotton has done much toward filling the coffers of the South. This condition holds with especial force for the planters in Georgia, Alabama, and Texas. But turpentine as much as cotton is cutting a figure in southern incomes. The discovery of the use of resins in the production of synthetic leathers and harder products like Bakelite has boomed the turpentine industry. Old stills that have been abandoned for years have reopened, and both owners and commission men find themselves buyers of automobiles.

In other parts of the South, diversified farming is demonstrating its profitableness. Grain crops and stock at new price levels are adding materially to farm revenues. This fact holds true particularly in Texas, where many of the smaller landholders in the last 2 years have become prospects for medium-priced automobiles.

Kokomo Rubber Refinanced

NEW YORK, Dec. 11—The Kokomo Rubber Co., Kokomo, Ind., organized in 1895 with a capital of $200,000, will soon incorporate under the laws of New York under the name of the Kokomo Tire Co. and will have a capital of 100,000 shares of stock of no par value. Fieldsteel & Co., this city, will underwrite 25,000 shares, 25,000 shares will be offered to stockholders and 50,000 will be held in the treasury.

This company, which has been manufacturing bicycle tires extensively, will develope its automobile tire business. It also manufactures automobile tubes. The officers will remain unchanged.

Annual earning, it is stated, will approximate $550,000. The old company has paid out $600,900 in cash dividends and $135,000 in stock dividends.

Decker Buys Universal Car Equipment

DETROIT, Dec. 11—The Decker Auto Top Co. has purchased the Universal Car Equipment Co., this city. The combination continues business as the Universal Car Equipment Co. The new combination is moving into a factory of its own with much larger manufacturing facilities.

Four Wheel Takes Over Utility

CLINTONVILLE, WIS., Dec. 11—The Four Wheel Tractor Co. has taken over the Utility Steel Tractor Co., Antigo, Wis., and will market the Utility tractor with improvements. David S. Stewart, who invented the Utility tractor, has opened an electric theatre in Appleton, Wis.

S. O. Raises Gasoline Prices

CHICAGO, Dec. 8—The Standard Oil Co. of Indiana has advanced the price of gasoline 1 cent a gallon to 16½ cents in all of its territory. In the Kansas City district Standard Oil and the independent companies have advanced prices 1 cent a gallon to 15.8 cents, tank-wagon basis.

Another increase of 1 cent a gal. in gasoline in 10 days has been made in Milwaukee, Wis., by the Standard Oil and independent companies. Current quotations are: 59-deg., 17.6 cents and 16.6 cents, filling station and tank wagon delivery respectively; 62-deg., 21 and 20 cents; 65-deg., 25.5 and 24.5 cents. Los Angeles prices have gone up 1 cent to 20 cents retail. The standard Oil and Union Oil companies are the leaders in the movement and so-called independent producers follow suit. The price of gasoline in Southern California has been raised 9 cents a gal. in the last 14 months.

Rubber Prices Are Higher

Para Reaches 98 Cents a Lb. and Ceylon 81 Cents—Crude Oil Quoting High

NEW YORK, Dec. 12—Rubber prices featured this week's activities in the automobile materials market. Prices fluctuated and closed yesterday higher. Para rose 2 cents a lb. to 81 and Ceylon rose to 83 cents a lb., a net gain of 6½ cents. Shipments have not been regular of late with the consequent rise. Lead prices went up 25 cents a 100 lb. to $8.00. Linseed oil rose 1 cent to 94. Tin dropped $1.25 per 100 lb. to $43.25.

The advance in rubber is attributed to several causes. The chief one is said to be the great delay experienced in ocean transportation between the Far East and London. Formerly, under normal conditions, a shipment of rubber could be brought from London in 45 days. Under present conditions it is not unusual for a cargo to be in transit for 3 months. There has been great delay also between London and New York. Against a voyage of seven days, often twenty-five days have been required in recent months.

In spite of an increased production of plantation rubber, these conditions have enabled speculators in London, and to some extent in this city, to bid up prices without buying very much of the product. Stocks in London are not large, but consumers in this country are said to be fairly well supplied.

It is estimated that the yield of plantation rubber for 1916 will be 160,000 tons, against 107,000 tons in 1915.

Crude oil prices are at present the highest in twenty years. The new production is small in volume, and the cost of drilling the wells is quite heavy. Pennsylvania crude oil is quoting at $2.75 per barrel. The previous record price was in 1895, when it was quoted at $2.60 a barrel. Indications point to $3 a barrel shortly.

Continental Asks for Stock Issue

DETROIT, Dec. 11—Stockholders of the Continental Motors Co. will be asked by the board of directors to approve a plan by which $15,000,000 common stock and $3,500,000 preferred will be issued. Each common stockholder will receive three shares for each share now held and $5 cash.

It is stated by the company that the purpose of the plan is to provide sufficient working capital to meet the needs of the concern. In addition, $1,000,000 funded debt will be paid off. The outstanding preferred stock of the company will be retired or exchanged for

new preferred stock. There is $472,300 preferred outstanding.

In their letters to the stockholders the company directors state that they have refused offers for control of the capital stock of the company. The plan, they say, has been approved by stockholders having 80 per cent of the stock. The directors have placed their stock with the Security Trust Co., which will act as depository, and ask that other stockholders do likewise.

Under the plan, a new committee will be formed under the supervision of a committee composed of B. F. Tobin, R. W. Judson, H. J. Warner and A. H. Zimmerman. The new stock issue will be handled by William P. Bonright & Co. and Lee, Higginson & Co. It is stated that the common stock taken by the bankers will be held for investment and will not be offered to the public.

—

Dividends Declared

Willys-Overland Co., regular quarterly of 1¾ per cent on preferred, payable Jan. 2 to stock of record Dec. 20.

—

E. & J. to Pay Dividend

DETROIT, Dec. 12—The Edmunds & Jones Corp. will pay its third dividend on Dec. 20, amounting to 1¾ per cent on the preferred stock and $1 per share on the common stock, according to a statement by G. D. Edmunds, president.

—

Pierce-Arrow Pfd. on 8% Basis

NEW YORK, Dec. 13—The Pierce-Arrow Motor Car Corp., Buffalo, has declared an initial dividend of 2 per cent, putting the stock on an 8 per cent per annum basis. This dividend will be payable Jan. 2 on stock held from Dec. 6 to Dec. 31, inclusive. Quarterly dividend payments will be made in January, April, July and October.

Securities Drop on Peace News

—

Chevrolet Drops 20 Points—United Motors 2 Points Lower —Market Weak

NEW YORK, Dec. 13—News of Germany's peace proposals was the cause of the widest break in stocks in the last 2 years. Heavy selling on the part of professionals was followed by liquidating orders from the commission houses. This selling movement continued until noon, when more than 1,000,000 shares had changed hands. After the second wave of selling, both on the Stock Exchange and the Curb, had receded, motor issues were found to have suffered badly.

Chevrolet was the largest loser with a drop of 20 points, General Motors dropped 7 points, and United Motors dropped 2 points. Stutz went down to 63, National dropped 2 points to 36, and Springfield Body common had a similar drop to 85.

Before the German news had been published, that is, for the week ending Saturday, automobile stocks were fairly active and higher. Ajax Rubber featured the market with a gain of 16½ points on the strength of the deal with the Racine Rubber Co., which is planned to be taken over by it. Ajax Rubber is now quoting at 86½. Stewart-Warner stock will be listed on the Stock Exchange.

—

Hayes Capital Now $1,500,000

DETROIT, Dec. 13—The Hayes Mfg. Co., body builder, this city, is increasing its capital to $1,500,000. The present capital consists of $500,000 in common, $135,000 preferred, and $60,000 in bonds. The company has a surplus of $440,000 for this year. A part of the increase in capital is a 75 per cent stock dividend, $625,000 worth of stock being issued in all. Earnings for the 5 months of the current year are $114,000.

—

Harrison Radiator Granted Charter

ALBANY, N. Y., Dec. 8—The Harrison Radiator Corp., Lockport, N. Y., has been granted a charter to manufacture radiators, parts and accessories. It is capitalized with 20,000 shares, half of no par value. It will carry on business with $1,050,000. The directors are Beononi Lockwood, F. A. Gaynor and R. G. Coad. This company was recently taken over by the United Motors Corp.

—

Phelps Capital to Be $400,000

COLUMBUS, OHIO, Dec. 9—The capital stock of the Phelps Mfg. Co. will be increased from $100,000 to $400,000 in the near future. The company is manufacturing wire wheels for automobiles.

—

Paige-Detroit Issues $1,000,000 Preferred Stock

NEW YORK, Dec. 8—The Paige-Detroit Motor Car Co., Detroit, has issued, through Chandler & Co., this city, $1,000,000 of 7 per cent cumulative preferred stock, par value $10 a share. The amount authorized is $1,500,000. The Paige-Detroit company also has $2,000,000 of common, par value $10, of which $1,500,000 has been issued.

The preferred stock will be redeemed at par and accrued dividends at the rate of $100,000 annually, beginning with Jan. 1, 1918, and ending with Jan. 1, 1927.

For the 13 months ended Dec. 31, 1916, the net income available for dividends was $609,755; for the 10 months ended Oct. 31, 1916, $964,442. Ten months'

Rickenbacher Sails for Europe

NEW YORK, Dec. 12—Ed. Rickenbacher, racing driver, sails for Europe Saturday to visit England, France and Italy to purchase two racing cars for next year's campaign in this counrty. He goes as a representative of Wm. Weightman, Kenova, Va., who made his debut in racing by driving a Duesenberg in the Astor Cup Race and later won third place in the recent Vanderbilt Cup Race in a Duesenberg. Rickenbacher expects to take the matter up with the Sunbeam Co. and has been approached by that organization to drive for them next summer. He prefers however to purchase cars outright. It is expected that he will visit Fiat and one or two of the French makers.

—

Boston to Have Salon

BOSTON, Dec. 9—Manager C. I. Campbell of the Boston automobile show today leased the ballroom of the Copley Plaza Hotel for the week of the Boston show in March to hold the automobile salon. While the Mechanics' Building exhibit is to open Saturday night, the salon will not open until Monday night. The exhibitors in the salon will be members of the Boston Automobile Dealers' Association. There will be a limit of not more than two cars for each dealer. Another restriction limits the exhibits to limousines, landaulets, coupes, sedans, etc., with the exemption that no open touring car whose price is less than $2,500 will be admitted.

—

Two More Show Exhibitors

NEW YORK, Dec. 12—The Craftsman Motor Co., Chicago, will be an exhibitor at both national shows. The Superior Lamp Mfg. Co., New York, has just been given space at the New York show.

Safety First Advocates Education

Punishment of Traffic Violators Censured at 3-Day Session of Association

BALTIMORE, MD., Dec. 7—Education will do more toward reducing accidents than punishing violators of traffic rules. Such was the keynote of the annual convention of the Safety First Federation of America, which opened a three-day session here to-day. With the ever-increasing volume of automobiles on our streets comes a corresponding increase in the traffic chaos of busy thoroughfares and a consequent need for more ease of movement of vehicular traffic and the necessity for extreme care on the part of pedestrians and operators of automobiles and horse-drawn vehicles alike.

Perhaps the one great message that was brought to the convention came with Joseph Sabath, now superior judge of Cook County, Ill., and former head and originator of the speeders' Court in Chicago. Judge Sabath's experience in handling some 20,000 cases in the speeders' court has given him a knowledge of motor traffic such as is possessed by few, if any, other individuals. It is his opinion that the problem confronting a judge in his former position requires something more than a cold administration of the law, the exacting of fines and penalties, the adding of revenue to the city treasury, something that the administration of the law does not reach—the question of guarding human life. "The levying of fines and penalties is insignificant," said Judge Sabath, "compared with the real service a judge in such a court can render the community if he takes the problem seriously and devotes himself to a study of the question and urges such remedies as his experience shows him to be best for all concerned."

In his plea for education as a substitute of penalization, Judge Sabath declared that the man who is fined usually leaves the court room defiant. His penalty is paid and he owes nothing more to society. However, if the judge patiently and earnestly points out to him the seriousness of his offense, because of its danger to society, his better self responds and he becomes a champion of the work the court is doing.

Summing up, Judge Sabath said that no mercy should be shown an intoxicated driver of a car, for he is a real menace, and a prison sentence should be meted out to him. Among other things he advocated as being necessary for greater safety on our streets are the abolishment of glaring headlights, better regulation of motorcycles, licensing of every person driving a car and the establishment of a special court in each city to handle violations of the traffic rules and run along educational lines.

Several speakers at the convention advocated that all vehicles be brought to a full stop a certain number of feet—preferably ten—back of a street car that has stopped to take on or discharge passengers, unless there is a safety zone or the street is sufficiently wide to allow the vehicle to pass and give passengers 8 to 10 ft. of space between the car and the vehicle passing.

Education both of the pedestrian and the vehicle operator in the principles of Safety First was the prevailing thought expressed.

Studebaker Six Has 122-in. Wheelbase

NEW YORK, Dec. 13—The wheelbase of the 1917 six-cylinder Studebaker is 122 in., and that of the four-cylinder model is 112 in. In the description of these cars published in THE AUTOMOBILE last week the four was incorrectly given as 102 in. and the six as 112.

—

Harkness Resigns as Sheepshead President

NEW YORK, Dec. 12—Harry S. Harkness has resigned as president of the Sheepshead Bay Speedway Corp., to take effect at once. No reason is given for his resignation. The speedway made little money this year and Mr. Harkness and other heavy stockholders were obliged to put up much money to cover the heavy expenses.

Analyzes After-War Conditions

(*Continued from page* 991)

will enjoy greater industrial stability resulting from a broader market."

Laws Must Change Slightly

The present laws, the report says, in many cases as they stand operate to prevent formation of co-operative organizations for export trade. Changes must be made, it says, to relieve the manufacturer of even doubt as to their application in foreign trade organization, but leaving them as at present to protect the domestic consumer against combinations to control prices.

Probably the most important part of the report is that which goes into detail touching the question of legislation under which the American exporter may be protected in his business, once peace is restored abroad.

Several months ago a preliminary report along this line was made by the Trade Commission, and following this action Representative A. Y. Webb, chairman of the House Judiciary Committee, introduced a bill covering the recom-

mendations made by the commission. Mr. Webb said to-day that he is prepared to push his bill at the present session of Congress.

The trade report suggests that unnecessary alarm is being felt by American exporters just at this time because of the fact that high costs of raw materials, increased taxes, probably higher wages, to say nothing of the capital and stocks of material necessary to repair the wastages of war, are expected to delay the full power of European competition until it regains its normal state. But laws to put the American exporter on a footing with his foreign rival by authorization of collective foreign selling agencies are recommended.

In studying the export situation the trade commission, it is declared, has tried to take the problem in its broad, historical aspect, considering the present war as a temporary interlude, the permanent influence of which it is difficult to estimate.

Competition Will Be Sharper

"It is frequently asserted," says the report, "the manufacturers and producers of the belligerent countries will take effective measures to regain their former trade. Such foreign manufacturers and producers may be expected to fully utilize their highly efficient organizations for the promotion and handling of trade beyond their borders, even foregoing profits or taking a very low profit till their costs again become normal and they have re-established their trade. Hence, competition from foreign industrial combinations, aided by foreign ship lines and foreign banks, and backed by foreign governments, may be even sharper than before the war."

Other Countries Considered

The report takes up competitive conditions in most of the countries of the world, devotes a chapter to competition in South America, gives competitive conditions in particular industries, and carries a mass of tables and statistical data concerning trade conditions everywhere.

Detroit Show Space All Sold

DETROIT, Dec. 8—Every square foot of floor-space for the 1917 Detroit automobile show has been sold. More space is available at the Billy Sunday tabernacle where the coming show will be held, than was at the disposal of the Detroit Automobile Dealers' Assn. last year but demands have been so great that members have been held down on space and non-members have been forced to tak cut allowances in order to partially meet the demand. As it is, there will be many pleasure car dealers and accessory companies who will be unable to display their exhibits.

Battery Service Discussed

—

Ind. Service Managers at Meeting—Advocate Co-operation by Garages and Owners

INDIANAPOLIS, IND., Dec. 10—Closer co-operation on the part of garage men and automobile owners with manufacturers as a means of eliminating many storage battery problems as they relate to starting and lighting systems was recommended at the regular monthly meeting of the Indiana Automobile Service Managers' Assn. held here last night. The meeting was attended by about seventy-five persons with members of the Indiana section of the Society of Automobile Engineers as guests.

"The Battery Service Problem" was the subject of a paper read by J. Whyte, service manager of the Prest-O-Lite Co. H. S. Bentley of Cleveland, manager of agents of the Willard Storage Battery Co., read a paper entitled "Proper Care of Batteries on Cars Held in Stock."

The chief topic of discussion among the service managers was the cold weather problems that result from the lack of care of storage batteries, and as a result of this discussion car manufacturers were asked to request their service men, agents, and owners to make the following recommendation for starting cars in cold weather:

> Throw the clutch out—do not keep it in neutral position—while trying to start engines in cold weather. By throwing out your clutch you relieve your starting battery of a heavy load, thereby increasing the efficiency of your starting system.

The service managers expressed the belief that not one motorist out of twenty-five knows of or practises this simple rule which would accomplish much in the elimination of battery and starting system troubles.

—

Earle & Boggs Take Buda Motor

NEW YORK, Dec. 12—Earle & Boggs, 1790 Broadway, New York City, manufacturers' representatives carrying a general line of automobile materials, have been appointed representatives of the Buda Co. in the East.

—

P. O. Bans Newspaper Publicity

(*Continued from page* 992)

and a similar article which might be an advertisement," said General Dockery. "Cases have been brought to our attention in which these alleged news items, undoubtedly written by the same fellow, have appeared in different publications. Therefore, in view of all the facts, while not saying the newspapers are violating the law, in view of complaints being made we are investigating.

"The construction of this law is very clear, and likewise the evident intention of Congress is very clear. Otherwise, Congress would not have gone so far as to make the violation of it a criminal offense, in addition to the denial of second-class mail privileges to the offenders. This particular feature is a part of the section of the law which calls for the publication, ever so often, of sworn statements as to ownership and circulation. As I said before, I hope the letters I am sending out, together with the possibility that I may have to call some of the offenders before me, will suffice. If not, I am then required by the law to have recourse to the courts, and the procedure would be to refer my complaints, together with the information obtained by me, to the United States District Attorneys in the territories where offenses seem to have been committed."

General Dockery then continued to discuss in an interesting manner his views as to the line of demarcation already referred to. He said, in this connection, that if a news notice and a display advertisement are run at the same time, and the two are apparently connected, the natural presumption would be that the news notice is in effect an advertisement, and if not so marked would be a violation of the law.

Traffic Men Indorse N. A. C. C. Methods

DETROIT, Dec. 13—Twenty-five traffic managers of leading automobile companies met here yesterday and voted to approve the methods of the National Automobile Chamber of Commerce traffic department for relieving freight congestion.

—

Madison Square Garden Sold

NEW YORK, Dec. 11—Madison Square Garden, the cradle of the automobile industry and the scene of exhibitions and spectacles of all descriptions for the last twenty-six years, has been put up on the block. Last week it was sold for $2,000,000 to the New York Life Insurance Co. Lovers of the staid old structure had visions of a modern building in its place, but the insurance company has since expressed its intention of selling it, so there is a slight chance that the building will continue to be for exhibition purposes.

In Madison Square Garden was held the first automobile show of this country. This was in 1900, and for thirteen consecutive years the place was the setting for the local national show. Each time since that rumors claimed the sale of the Garden. When the industry enlarged and more room was needed to harbor the show, a worthy successor to the historic old building was found in the Grand Central Palace.

Carbureter Demands

THE attitudes of the purchasing agent and the engineer of an automobile factory are typical of the problems the carbureter maker of to-day has to solve. The purchasing agent looks upon the carbureter as a necessary piece of brass which must be bought to make the car complete, but which, like all other equipment, must be bought at the lowest possible figure.

On the other hand, there is the engineer, who knows he has a fine power plant, but must have the best possible carbureter in order to bring out the power of which it is capable. He wants 3 m.p.h. on high. He wants quick starting after a night in a zero-temperature garage. He demands acceleration from 3 to 30 m.p.h. in a city block, and all this at a reasonable economy figure and with a high peak on the power curve.

To meet these standpoints of the purchasing agent and of the engineer offers a problem that does not tempt the faint-hearted. In fact, more than one carbureter maker who believes that he has a good instrument will not even attempt to bid for factory business. Instead these manufacturers go after the retail trade, and more than one are successful.

To be a commercial success, however, the carbureter of to-day is like the rest of the car. It must not only be designed to do its work in the best possible manner, but it must be a commercial proposition which adapts itself to quantity production. It must not have to be hand-filed and lapped after entering the assembly room. It must come through so that the assembly is a matter of course and not a matter of expediency. Every carbureter, in other words, must go through alike and not be hand fitted in the assembly process.

City Exits

THE wider use of the automobile is restricted to-day due to several of our largest cities not having adequate exits and further not having adequate streets leading into the main business centers from residential sections. The first situation, that of insufficient exits, is serious. The automobile has largely changed the face of city life. The man of wealth no longer lives where he was 10 years ago. The street he then lived on is to-day a fashionable business street. His residence is now 15, 20 or 30 miles out. The railroad train is at his service but many prefer the automobile. The use of the automobile for such service will increase, but its increase will largely depend on the street facilities. If an hour or more will be needed to get out of the traffic zone as at present in some cities, then the automobile's use in this respect will be unfortunately restricted. What is needed is a wide street, preferably with double roadways and if possible no trolley crossings. This is impossible in some cities but it is not improbable that there will in the next 10 years be elevated roadways for motor travel leading out of our cities. The automobile is of sufficient importance to-day to demand such. In at least six or seven largest cities the elevated motor road is not only a possibility, but very much of a probability. New York, Chicago, Boston and other cities need such to-day. New York is perhaps the easiest city to get out of in America. On the other hand, Boston and Chicago are among the worst. Wider exits are questions that our makers should give attention to, and they are problems that can be handled better and cheaper to-day than 10 years hence.

A. C. Newby

THE withdrawal of A. C. Newby of the National company from the active management of the company is an opportune time for rendering unto Caesar that which is Caesar's, etc. Mr. Newby, while not one of the most conspicuous figures in the automobile field, has been a good representative of that conservative element in the industry which has served so as a stabilizing influence throughout the varying vicissitudes the industry has passed through. He was one of the pioneers in the field, first with the electric vehicle industry and then with the gasoline type of vehicle. Every manufacturer has admired that stalwart spirit of honesty which has been a part of every word and action of Mr. Newby. In the automobile contest field the same spirit had an inspiring influence and Newby was a force for good in automobile racing at a time when such an influence was highly essential.

Germany After the War

By Edward Allen Langdon*

¶ Germany has all told nearly 300,000 automobiles in use to-day.
¶ Germany is now using approximately 160,000 automobiles in the war—one-half on the Western front, one-fifth on Russian, and the remainder in the Near East.
¶ There will be a demand for 300,000 to 500,000 automobiles in Germany after the war closes.
¶ After the war it will be impossible to market automobiles in Germany unless there are good U. S. A. service stations there.
¶ Germany will buy automobiles as a unit and not as individuals after the war.
¶ Germany will offer a good market for U. S. A. accessories and parts.
¶ Adoption of metric system of measurement will gain headway after the war.

GERMANY, while carrying on a warfare admitted to be highly efficient by her very enemies, is already making extensive preparations for the time when peace shall have been restored. This holds good of every department of national life, industry, finance and trade, as well as agriculture and countless illustrations of this activity could be cited. Instead, the following remarks will be limited to the automobile situation, and particularly to those phases thereof which are of necessity of practical interest to American makers and exporters of automobiles.

160,000 Cars Used by Empire

While the official figures are impossible to obtain, thanks to the intense secrecy which surrounds all data of any direct or indirect military importance, the ideas of people inofficially in touch with the situation indicate that the State, *i.e.*, the Empire, is now using close to 160,000 automobiles. One-half of these are in service at the Western front, one-fifth along the Eastern front between Riga and Lemberg and the remainder along the Rumanian and Saloniki fronts.

Besides, there are now in Government service perhaps 50,000 machines far carrying officials and industrial products in Germany herself, and perhaps the same number is employed for private purposes. In all, there are in Germany between 250,000 and 300,000 motor vehicles, and as these are being used up the supply is being replenished; but there is hardly any increase of the total number, because the automobiles on hand are sufficient for German requirements, and also because the raw materials are more urgently needed in the making of munitions, which industry during the last few months has been pushed more energetically than ever before.

The automobiles, the number of which is practically constant, will however not be considered efficient when the war is over and money once more will have to be reckoned with. For this reason it is safe to predict that after the war two-thirds of the automobiles will be replaced by new ones, and it is understood that this will be done on the following plan. The Government will keep the machines commandeered during the war, to be rebuilt and used, either for public works, or to be sold practically at cost to small agricultural individuals or concerns, so as to facilitate farming. On the other hand, the former owners of these cars will receive a Government subsidy of from 45 to 65 per cent toward the purchase of new automobiles built in Germany along standard lines and approved in their specifications by the Imperial Government. Thus, there will be a sure demand in Germany, immediately after the war, for about 200,000 cars.

Horses Are Scarce

But this is not all. Before the war, horses were still extensively used in German cities as well as in the country. They are now very much decimated and it is doubtful whether raising horses will be favored by the Government, and it must be understood that Government control of all economic affairs is a thing growing in Germany by leaps and bounds. Horses have not only proved vastly inferior to motor equipment, but were also somewhat of a disappointment to the German stomach. Very likely all the energy formerly turned toward raising horses will, after the war, be devoted to cattle breeding, and the millions of working horses will have to be replaced somehow.

A 1,000,000-Car Market

If the war ends within a year, assuming developments somewhat similar to the past, Germany will have a population of 60,000,000 people when peace is made. The Empire will then be a highly industrial country and therefore require ample facilities for transporting passengers and merchandise. If the demand will be for one machine to every sixty of the

*EDITOR'S NOTE—Edward Allen Langdon has for many months been in different parts of Europe studying automobile conditions in those countries. Mr. Langdon is a critical student of conditions. He is making a comprehensive study of trade and all his utterances savor of conservatism.

population, the market will call for a million automobiles, of which Germany will be able to supply, with international conditions restored to normal, from 50 to 70 per cent. There still remains a market for from 300,000 to 500,000 automobiles of simple, strong construction, efficient in operation and moderately priced which could be supplied by American exporters.

Points to Be Considered

Following are the points to be considered by German buyers:

1—*Fuel Economy.*—Efficient operation will be as necessary after the war as it is now. Taxation will be high, there will probably be a general and fairly high tariff, and every cent will count.

2—*Durability.*—Automobiles will be driven by careful, well-taught drivers, of whom there are now hundreds of thousands, thanks to the army training. Nevertheless, each automobile will always be worked to its full capacity, and wherever seven-passenger touring cars or five-ton trucks are bought, they will be expected and called upon to prove their true character every minute of a working day.

3—*Diversity of Fuel.*—It is quite likely that industrial alcohol and benzol will be cheaper than gasoline after the war, as they were already before its outbreak. Other things being equal, motors adapted for such fuels will have a point in their favor over ordinary gasoline motors.

4—*Agricultural Field.*—Many thousand of cars will be required which are of the passenger type, lightly built, of 18 to 24 hp. and adaptable to driving agricultural implements, such as ploughs, hoes, spreaders, etc. These machines will have to be very simple and very strong in construction and it will be necessary to not only give clear demonstrations of their ability to do the work, but to submit doubtless proof of past performances.

5—*Passenger Cars.*—They should be completely equipped, with self starters and electric lighting, high-tension ignition and substantial tires.

6—*Trucks.*—Simplicity of design and strength will be the chief features looked for, but starting and other equipment will count, as many machines will be driven by women who have now assumed a definite position in Germany's industrial life. Electric trucks will find a specially good field in the industrial cities.

Service Absolutely Necessary

7—*Service.*—It will be almost impossible to market an automobile in Germany, unless there is a service station including a complete stock of repair parts within the Empire.

It is now almost certain that Germany will buy abroad, and perhaps also from importers in the Empire, as one corporation, with the double advantage of eliminating competition among bidders and also of enormously reducing overhead expense. This does not mean, however, that trading with Germany will not be profitable; only, it will be necessary for American business men to meet efficiency with efficiency. In other words, if Germany's automobile industry and the users of automobiles in Germany will face the world market as a solid financial unit, Americans will have to adopt the same policy, at least in dealing with Germany.

Co-operation Favored

The German Empire does not know the reactionary unscientific legislation against progressive concentration in business and rather favors than hampers it. Therefore, American automobile dealers in Germany can quite well work together, conducting a permanent automobile exhibit in Berlin, Frankfort-on-Main, Leipzig and one or two more of the most important centers, using corporate advertising and letting their salesmen work hand in hand, distributing the products of all the companies to best advantage.

As has been said, taxation and duty will be high in Germany after the war, and only very efficient management will be able to successfully combat these handicaps. Duty on chassis and cars will most likely be higher than on automobile parts, and here the opportunity for the parts manufacturer begins. Motors, axles, steering and transmission gears, which America can easily supply, and which would come up to Germany's demand both in regard to quality and quantity, should find a ready and highly profitable market in the German Empire.

The same holds true of certain classes of equipment, especially electric starting and lighting sets. There is less opportunity for makers of speedometers and particularly delicate instruments, as the class of labor required for such manufactures is specially cheap in Germany.

Look to U. S. A. Industry

To some people consideration of all these points may seem premature, but if Germany who is at war considers them of sufficient importance to give them at least initial attention, American manufacturers ought not to overlook their possibilities. In fact, when the magnitude of this field is considered and that the business to be done is bound to amount to hundreds of millions, it is not surprising that Germans engaged in the automobile business are expecting the American industry to take well-organized steps toward capturing the lion's share of this business.

If the U. S. A. automobile industry, as a body, should approach the German government, it would in all likelihood succeed in obtaining for the buyers of U. S. A. cars, if not the same, then at least part of the subsidy extended to purchasers of native cars conforming with Government specifications. Perhaps, if the Government should feel unwilling to take such a course, an agreement could be obtained for a short term, say 2 to 5 years.

Getting a Foothold

Even if the market for American cars should be made more difficult after such an introductory period, many users would thereafter stick to the American product if it gave them satisfaction. This point, of getting a foothold in Germany immediately after the war, is the more important, as interests across the Channel will hardly be sentimental enough to sidestep profitable business with Germany, and as the very machine tools now making munitions against the Empire will then be used for making other, and marketable, products.

Before the war, Germany was England's best customer; after the war, if she can do so without serious loss, she will prefer to buy from others than her former enemies wherever possible, without declaring any distinct trade war.

Subsidies Are Possible

This immediately brings to the light another point, which is only of indirect bearing on the automobile situation, namely, that subsidies for cars built along lines approved by the Government will, as has been mentioned, be continued vigorously. This, however, indicates nothing more or less than the preparation for a renewal of the conflict now going on. As a matter of fact, well-informed Germans even to-day admit that, while they are perfectly confident as to the result of the war, they do not expect it to bring a definite decision; but they do expect that when the struggle is renewed they will have more friends among the nations than before the present war. From this viewpoint, Germany will very likely be ready to make greater advances in its trade relations to America than in the past, and this will be specially true where products of military value, such as automobiles, are concerned.

Another point to be remembered in dealing with Germany is that unless the war will continue to the utter exhaustion of Europe, its end may find Germany dominant in the Near

East, directing the affairs, in a larger sense, of not only Austria-Hungary and Bulgaria, but of Turkey, the Balkans and very lik ly Italy, with a strong influence in Scandinavia thrown in. Therefore the relations of any power with Germany will materially weigh in determining its dealings with the countries belonging to the German sphere of influence, which sphere during the past 18 months has been constantly increased. From this viewpoint, too, German business will pay.

Present Conditions Temporary

There are quite a number of materials formerly imported into Germany but now not available, due to the blockade. For most if not all of these serviceable substitutes have been found and the Germans are as a matter of course very enthusiastic over all these discoveries. There is no doubt, however, that a great many of these substitutes though they made fine makeshifts will not prove commercial when peace returns; although it may be that with some additional experimenting and study they *may* develop into profitable propositions. The fact that an article found extensive use during the war has almost nothing to do with the possibility of producing it profitably, or even, for that matter, without a loss.

It must be remembered that the consideration for profit, at least from the State's point of view, is being completely thrown to the winds for the time of the war's duration. The Government pays liberally for everything, money circulates at a very lively rate and everybody makes plenty of it. But, as remarked, these conditions will almost instantaneously cease with the war. Hence, a great many effective substitutes unless profitable in competition with the original articles will disappear.

Rubber Most Important

The most important of these products, so far as the automobile industry is concerned, is rubber. The Germans claim that they are now using a lot of synthetic rubber, and from the fact that automobiles are equipped with the necessary tires, it would seem that their statement is correct. It is not so certain, however, that the production of the synthetic product will be able to continue after the war, in competition with natural rubber; and here, too, there may yet be a very great field for American manufacturers. The competition in the normal European market, so far as tires are concerned, includes a considerable supply of English and French made goods; for which reason the above remarks, referring to the need of Americans being awake to the very earliest trading opportunities offered by Germany after the end of the war, hold true in the tire field also.

Parts and Accessories in Demand

When the chance and probability of hundreds of thousands of American cars being sold in Germany, is considered, it follows that reserve parts and accessories, from springs to spark plugs, will find a ready market here, too, as long as these American cars are used and continue to come in. Accessory and parts makers and tire exporters, for that matter, also will do well to consider the same principles of economy and efficiency in German exporting as were laid down in the foregoing remarks for makers of automobiles.

Poland May Develop

The European war, reducing Europe to two spheres of interest and influence, as it is bound to, will also bring into prominence once more the world-wide adoption of the metric system. There is a considerable probability, according to the opinion not only of German but of neutral engineers as well, that England will very soon and completely adopt the general use of the decimal system for weights and measures. This will be one of the minor effects of the war, but will be of considerable bearing upon international trade in products made according to mathematically exact measurements.

Although officially independent of Germany, the new Kingdom of Poland, one-quarter as great as Germany and populated by almost 15,000,000 people, will present a noteworthy market resembling in many respects that of the Empire itself. Poland is a rich grain country, although the population up to now has been anything but prosperous, and very likely will now be developed not only to greater agricultural efficiency, but also into an industrial section of quite some importance. The country is level and the roads not as bad as 2 years ago. The Germans are already doing a good deal in modernizing conditions and soon after the war Poland ought to offer a good market.

In a way, this holds true of the Balkan States, too, which have once more been roused to more modern ideas and methods by the war. No matter what the political distribution after the war, the territories now known as Servia, Bulgaria, Rumania and Greece will be in the market for all sorts of modern appliances, including automobiles and kindred products.

Must Begin Now

As has been stated in the introductory paragraph, only the most striking features of the situation now developing in Germany are given attention here, and a great deal will be left to the ingenuity of American business men regarding the best way of getting the business to be obtained in the Empire and its Confederate States. Too much stress, however, cannot be laid on the point that conditions should be studied and plans outlined—as far as possible—now, without waiting for the end of the war. Capable people should be despatched to the Continent to look matters over and so far as can be done now, prepare for commercial relations to be taken up as soon as normal conditions are restored again. The earlier this is done, the more favorable will be the conditions American manufacturers will be able to obtain in dealing with the authorities handling these matters.

After the War

To sum it all up in so many words:

After the war, more than ever before, the devil is bound to take the hindmost; and the hindmost will be everybody who will fail to realize very early that the whole fabric of European economic life is being completely rewarped by the war.

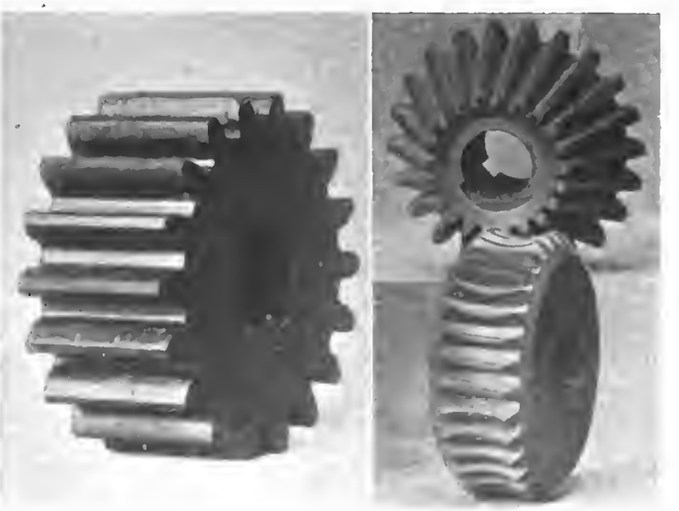
Westinghouse Noiseless Bakelite Gears



Examples of gears made by the Westinghouse Electric & Mfg. Co. from Bakelite-Micarta-D. This material is claimed to be almost noiseless in operation and to be so strong that it can be used without metallic inserts for timing gears. It machines easily, takes a high polish and is not affected by oil

Four Is Ultimate Engine

Sixes, Eights and Twelves Have Special Uses but Four Is Automobile Engine of Greatest Value—Production Restricts Development

By A. P. Brush *

ISN'T the four-cylinder engine coming back? Will the four-cylinder engine ever come back? As a matter of fact, the four-cylinder engine isn't coming back and never will come back. Such a thing is impossible, for the very simple reason that it has never gone out.

Considered solely from the standpoint of numbers, the four-cylinder engine is, and has been for the last 10 years, the standard prime mover for self-propelled road vehicles and, in my judgment, will continue to be so long as the four-cycle internal-combustion engine holds its place as the most satisfactory prime mover for mobile use. Other engines of the four-cycle internal-combustion type, such as the six-, the eight- and the twelve-cylinder forms, are more or less special engines built for the purpose of securing results outside the range and capacity of the four.

Naturally the question will suggest itself, if the four-cylinder engine is susceptible of development and improvement, and if it is even numerically the most popular engine and has the greatest amount of capital invested in its production, is it not reasonable to suppose that its development has been carried further than that of any other mobile prime mover?

Multi-Cylinder Development

It is my opinion that the six-, the eight- and the twelve-cylinder have all been developed more nearly to their ultimate possibilities than has the four-cylinder engine, and it is also my opinion that the greatest obstruction to the development of the four-cylinder toward its ultimate possibilities has been and is its very popularity. *Volume of production makes for efficiency of production and stagnation of development.*

The production engineer has carried his work nearer to the ultimate with respect to the four-cylinder than with respect to the six, the eight or the twelve, but to secure this result the production engineer has been an obstructionist as regards the development engineer. With his face set firmly in the direction of efficiency in production, he has been, with equal fixedness, opposed to change, because change is the arch enemy of production efficiency.

Progress in design, so far as the large-quantity manufacturer of four-cylinder-engine cars is concerned, may be said to originate only in the minds of the sales department, finding its expression in their effusions, to the end that it may exist as an hallucination in the mind of the ultimate consumer.

Production vs. Engineering Progress

While the foregoing may sound like an arraignment of the large manufacturers of four-cylinder-engined cars, I for one do not consider it as such. The efficiency of production that has been achieved was only possible because of this artificial stagnation in engineering progress. My only purpose in bringing these conditions as regards the four-cylinder engine to your attention is that these conditions are, to my mind, justification for the statement that relatively more progress can be made in the design of the four-cylinder engine than in any of the other types.

A Commercial Angle

There is another very real obstruction to the development of the four-cylinder engine. It has come to be accepted as the engine for the extremely low-priced automobile. It is, of course, possible that these Kresges and Woolworths of the automobile industry are producing the only marketable type of light-weight car of limited passenger capacity. That is a commercial rather than an engineering question and, technically at least, outside our consideration at this time. For use in the so-called pleasure type of automobile the four-cylinder engine is pre-eminently the engine to be used in light-weight cars whose ultimate owners are their own chauffeurs and mechanics. Right here I want to venture the opinion that this class of user is entitled to, and a considerable proportion are willing to pay a reasonable addition for, better car performance and higher comfort value combined with the same or greater simplicity and compactness of mechanism.

Let us consider first the question of performance. Four of the leading manufacturers of four-cylinder cars claim for their engines maximum horsepower per cubic inch of piston displacement ranging from 0.142 to 0.206, with total piston displacements ranging from 170 cu. in. to 213 cu. in., and maximum total horsepowers ranging from 25 to 35.

During the past year a four-cylinder engine has been designed, tested, and its production in a light-weight car has been arranged for. The cylinder dimensions are 3¼ in. by 4½ in., giving a piston displacement of just under 150 cu. in. Its maximum power, as determined by exhaustive dynamometer tests, is just over 44, giving a horsepower per cubic inch value of 0.29. Comparing this with the best four-cylinder engines previously referred to, you will find an increase of over 40 per cent in power output per cubic inch of piston displacement and an increase of over 25 per cent in total horsepower available.

Performance the Question

Comparing maximum horsepower output does not tell the whole story. Good performance in an automobile means, in the engine, a high power output throughout a wide percentage range of speed. In this respect this little engine probably surpasses its popular predecessors to at least an equal degree. Owing to the absence of published power curves I cannot make a direct comparison in this respect. I can only tell you that it excelled the maximum power output per cubic inch of its predecessors throughout a range of over 2000 r.p.m.; that is, it developed over 0.2 h.p. per cubic inch from 400 r.p.m. to 2600 r.p.m. Because of its smaller cylinder diameter, and, further, because of the fact that it is of the two-bearing-crankshaft type, this engine occupies much less room in the car than any of the other engines used for comparison. This means, of course, either more passenger room and comfort for a given wheelbase or the same passenger room and comfort with less wheelbase. These comparisons,

*Paper read before Buffalo Engineering Society, Dec. 13.

I think, clearly demonstrate the possibility of increased performance values in the light-weight four-cylinder car.

Now, let us see what are the results in comfort value. The objectionable characteristics of a four-cylinder engine are vibration at high speed, due to the weight of the pistons and the angularity of the connecting-rods, and another class of vibration which may be described as torque vibration, due to the relatively heavy and infrequent torque impulses at very low speeds. Obviously these smaller cylinder dimensions mean a reduction in piston weight, with a consequent reduction in vibration tendencies at high speeds, and because of its greater speed range it is obviously possible and advisable to use a lower rear-axle gear ratio, which means, of course, greater frequency of impulse and therefore less torque vibrations at low speeds. This marked increase in performance and comfort value has been secured with no increase in the complication of the mechanism which the owner-user must understand and care for, and production efficiency is equal, with very little if any increase in engine cost.

Valves Are Adequate

To avoid making this paper too long I shall give you only the briefest possible résumé of the essential details which were the means employed to secure the results outlined. The little engine is of the overhead-valve type, and, by the omission of valve cages and some other minor details of arrangement, valves of adequate size were used. Having secured valves of adequate capacity, the next problem was to secure a carbureter and manifolding arrangement which would give somewhere near maximum power at high speed and not destroy the engine performance at low speed. This result was secured by means of what may be described as a low-velocity down-draft dry manifold.

The Lubrication Problem

The next difficulty encountered was the failure of conventional lubricating systems to function properly in an engine of large power output and extreme speed and power range. This difficulty was overcome by using an oiling system which automatically controls the temperature of the crankshaft and its bearings, which gives a positive delivery of oil to the crankshaft and crankpin bearings, and which is interconnected to the engine throttle so as to vary the oil pressure with variations in power output.

To secure compactness the center bearing of the crankshaft was omitted, distortion of the crankshaft at high speed being prevented by fully counterbalancing the shaft and also by the use of an extremely rigid shaft, the crankpin diameters being 2¼ in., with crank cheeks of equal rigidity. I have given you this brief outline of the results obtained in this engine and the essentials of design by which these results were obtained, not as an example of ultimate possibilities but simply as one example showing a substantial advance toward that ultimate.

Warming a Manifold for Using Heavy Fuel

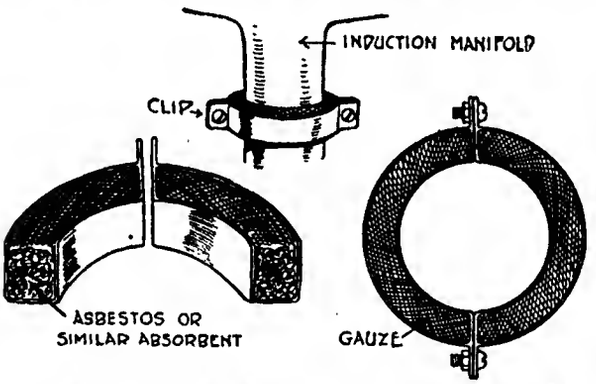
A SIMPLE method for warming up an induction manifold so as to enable an engine to be started on kerosene or something nearly as heavy without the use of gasoline, is described in a recent issue of *Motor Traction*, London, as the Wilkes method.

"The apparatus (which has been patented), as will be seen from the illustration, is an exceedingly simple and valuable asset. The small methylated alcohol stoves which are used in many households for the emergency warming of a small saucepan or kettle are well known, and it is this principle which has been adopted for warming up the induction pipe prior to starting.

"The arrangement consists of shallow metal circular or annular cups attached by suitable clips to the induction pipe immediately above the jet. The base of these circular cups is filled with asbestos wool or similar material, which is covered on the upper surface with fine wire gauze. Into these cups is poured the substitute or other suitable fuel, which impregnates the asbestos wool; this is ignited by means of a match or otherwise, producing a flame which burns for some time around the induction pipe, warming the latter sufficiently to obviate condensation, assisting the vaporizing of the liquid from the jet, and thereby rendering starting quite easy. In practice the time necessary on a standard Zenith carbureter for starting from dead cold has, we learn, been proved to be only 3 min.

"For purposes of running when once the engine is started, it is desirable to fit an exhaust-heated pipe immediately over the carbureter jet, so that vaporization of the fuel is assisted, such additional exhaust pipe being included in the patent specification.

"We understand the apparatus has been thoroughly tried and has proved most satisfactory in practice. When once the engine has been warmed up it will usually restart within a reasonable period by use of the handle only in the usual way."



Details of Wilkes method of starting on heavy fuel

Committees on Welfare Work at Reo Plant

THE Reo Motor Car Co., Lansing, Mich., is devoting many efforts toward welfare work for employees. A number of interesting and valuable methods devised to aid workers have been installed. The welfare work branches into a number of different departments and is done under supervision of department heads or by committees of men and foremen.

The safety committee comprises a chairman who gives his entire time to this work, and seven members each representing a division of the factory. Through this committee a constant oversight is maintained on the machines and safety appliances and the practices of the employees using them. Financial aid is given men, first through a fair wage, the minimum at the factory being 30 cents an hour. And a man in financial trouble receives additional help if the case is worthy by means of temporary loans or adjustment with the creditors.

A real estate commitee advises employees in the purchase of homes or the sale of real estate and is a great aid to foreigners unacquainted with conditions.

The company also maintains a first aid and hospital service, an industrial hall seating 1600, four bowling alleys, a library and dining rooms. They are at present erecting a clubhouse for employees which will probably be completed in December.

Pressure Lubrication Advantages

Theory of High Pressure Oil Feeding Borne Out by Experiment — Difficulty in Applying Very High Pressures to Automobile Engines — Importance of Cooling Effect of Oil on Bearings

By A. Ludlow Clayden

THE reason that splash lubrication is still more used than the pressure system is not entirely because the former is cheaper to manufacture. In an automobile engine the problem of keeping oil out of the cylinders has been more absorbing than the other problem of insuring enough for the bearings. With splash oiling it is easier to prevent overlubrication than with a pressure system, and splash oiling will, when well designed, give the bearings a supply sufficient to insure a reasonable life for the bushings.

On the other hand, bearings fed with oil under high pressure will outlast similar bearings fed by splash; they *can* be made almost everlasting. Engines have been built in which the crankshaft and connecting-rod bearings were able to keep their original tightness for 50,000 car miles. Give such an engine enough clean oil at regular intervals and you can almost forget that it has any bearings in it. Of course engine bearings in any good motor require renewal only at long intervals, so that they are not very costly to keep in repair, but everything that can be done to lengthen the period during which a car will run without mechanical attention is worth doing. Rear axles used to need tearing down and inspecting every 5000 miles or so. Now they will operate for years without any adjustment. It is but seldom now that a gear in the transmission has to be replaced, and ball and roller bearings have reached a pitch of perfection that enables them to outlast the gears. Even clutch facings now last an immense time, and the only part of the electrical equipment that needs much attention is the battery.

The day is in sight when an automobile will run for five years with no more attention than supply of lubricant and perhaps an annual wash out with kerosene before filling up with fresh oil. This is the reason why it is worth while to try to improve upon engine lubrication, which is already quite reasonably good.

From the viewpoint of the bearings in an engine we should design the lubrication without regard to the cylinders and, having cared for the bearings properly, we can then devise means for preventing cylinder flooding.

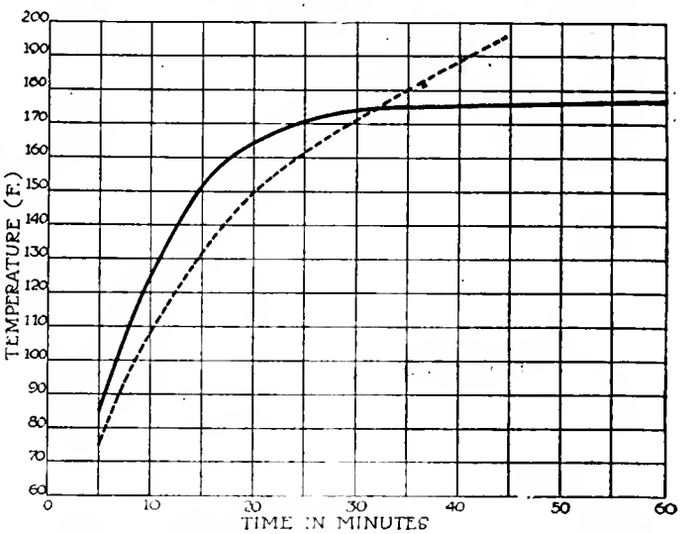
Theory of Pressure Oiling

The theory of lubrication has made a study for engineers of all nations for many years, and there are points which are still undecided. There are, however, a few simple rules which are accepted as fundamental.

1. Frictional resistance of a bearing decreases as the thickness of the oil film increases.
2. The loading for a given speed must not exceed a certain limit at which the oil film breaks down.
3. This limit is raised by making the bearing longer, because this increases the cooling effect of the oil.
4. The oil temperature varies throughout the bearing, being greatest where the oil film is thinnest.
5. Oil grooves placed wrongly may destroy the continuity of the film and so actually prevent proper lubrication whatever the oil supply.
6. A bearing with a reciprocating load is easier to lubricate than one with a constant load, as the relief of loading allows the entrance of oil (if it were not for this, splash lubrication for automobile engines would be impossible).

The value of pressure lubrication is mainly explained by item 1. We can regard the shaft and the bushing as being separated by a thin layer of jelly. When the load comes on, this jelly will be compressed on one side and allowed to expand on the other. Now, with a lubricated bearing the shaft and bushing ought not to touch. The frictional resistance is due to the force required to "shear" the oil film. The power required to do this decreases as the film grows thicker. Returning to the jelly illustration, it is obvious that the amount which the load would move the shaft relative to the bushing must depend upon the strength of the jelly. If the jelly is viscous it will resist displacement better than if it is thin. Actually, in a bearing, the effect of shearing the oil film is to heat the oil, thereby reducing its viscosity. If we can remove the oil as fast as it is heated, replacing the hot oil with cold lubricant, the viscosity can be maintained, and the shaft kept more nearly concentric with the bushing.

The function of pressure is to compel the continuous change of oil in the bearing. The cold oil being forced in drives the hot oil before it, giving it a chance to recover its viscosity before it returns to the bearing again. It is also beneficial in another way. Regarding the bearing as containing oil that can only escape at the ends, we see that the outlet consists of two narrow rings equivalent to a slit, twice the circumference of the bearing in length, and of a width equal to the clearance between the shaft and the bushing. No liquid will flow through a slit or other orifice in direct proportion to the pressure behind it, but in a proportion that decreases as the pressure rises. If a certain quantity flows



Effect of circumferential groove in bushing in reducing temperature. In this test the most efficient cooling, as shown by the full line curve, was obtained with a simple central groove to feed oil under the 40 lb. pressure. The other curve shows the greater rise of temperature when oil was fed to two longitudinal grooves close together and connected

out when there is a 5-lb. pressure behind, then less than double that amount will escape when the pressure is 10 lb. When the pressure on the oil supply is small the bearing is not kept completely full. With splash oiling, for example, the oil enters by suction of a sort. The oil in the bearing is squeezed out by the load on the shaft, and a partial vacuum is left in its place. This enables the atmospheric pressure on adjacent oil to drive it into the bearing, so displacing the vacuum.

Now with pressure-fed oil the bearing is kept permanently full, which means that the oil film is always as thick as possible; there are no variations in film thickness except those due to the oscillations of the load. Experiments made on bearings have shown that the friction decreased steadily as the oil pressure increased. In one particular experiment made on a steam engine giving 120 hp. at 450 r.p.m. it was proved that the friction horsepower was 3.33 with splash-fed oil and that this dropped to 2.13 with an oil pressure of 30 lb. per square inch, a steady fall in friction being noticed as the oil pressure was raised in small stages from nothing up to 30 lb. This is just one from a long series of similar experiments all showing the same thing, namely, that the power absorbed by friction in a bearing decreases as the oil pressure increases.

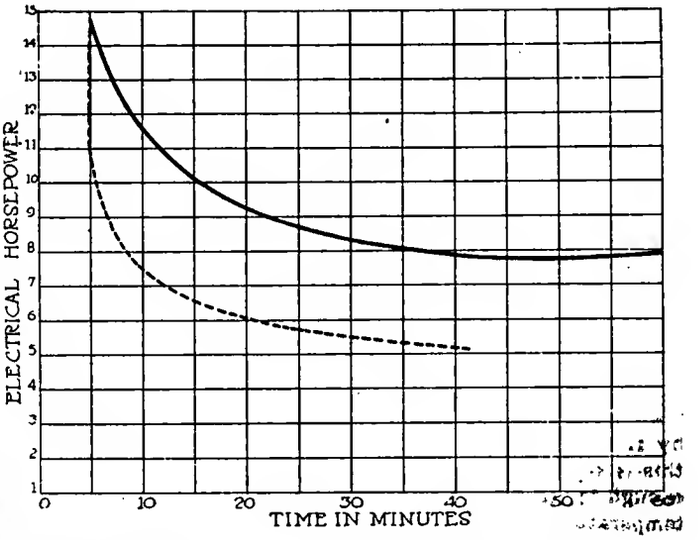
Precisely why this is remains a matter for argument, but some idea of the effect of high pressure oil may be obtained from the following analogy, which is not strictly a parallel case, though it serves to show the idea.

Suppose we regard the oil film round the shaft as a pneumatic tire and imagine that a series of rapidly varying loads are put on the shaft; then, obviously, the greater the pressure in the tire the less will the shaft move as the loads vary. If the tire is soft a big load may absolutely flatten it, driving out all air at one place; if the tire is hard this will not happen.

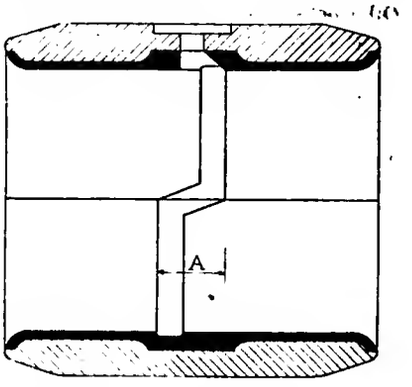
So with an oil film; one under high pressure will keep the shaft away from the bush while one under no pressure may be broken down by a sudden heavy load. An oil film in a bearing may be likened to the tire mentioned above, but with a constant leak in it, so that air is escaping all the time and has to be replaced.

Pumping Action of Bearing

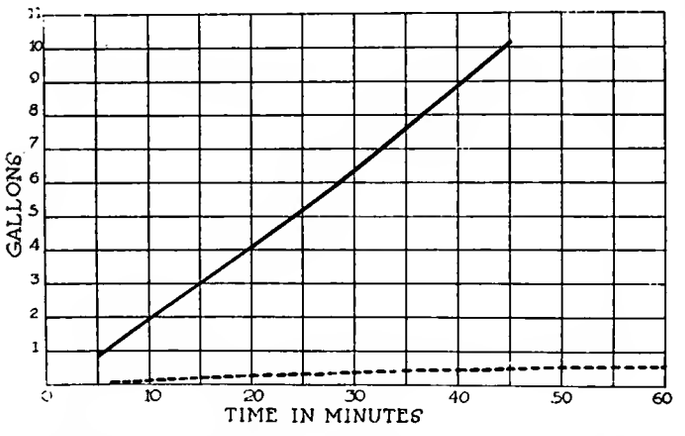
Luckily, a rotating shaft in a bushing is itself an oil pump. If it were not, lubrication by any other method than forced oil would be impossible. To use another rough analogy, suppose the shaft to have a series of blades on it and to be floating central with the bushing with the tips of the blades just clearing the bushing. Now put a load on the shaft so as to displace it relative to the bush, and we see that the space between the tip of the blade and the bush will be greatest on the side of no load and least on the side where the bush is supporting the shaft. Now imagine the shaft to be turning and the oil clinging to the surface of the bush. A blade descending toward the place of least resistance will be carrying a certain quantity of oil before it, and as the clearance decreases some of this oil has to escape. But the nearer the blade gets to the bottom the narrower will be the clearance through which such escape can occur; thus the pressure in the oil at the point of smallest clearance will be a maximum. In actual fact the point of smallest clearance is *not* directly opposite the point of loading, except when the shaft is not turning. The shaft carries the point of maximum oil pressure a little past the point opposite to the load, the exact location depending upon the speed of rotation.



Above — Curves from same pair of bearings showing the electrical horsepower taken to drive the shaft under load. After the state of equilibrium had been reached the bearing with the more copious lubrication required more power to drive it, but the bearing with the restricted supply was too hot to be safe to run further after 40 min.



Right—Groove for obtaining the best flow of oil in a bearing supplied with oil under pressure



These curves show the relative quantities of oil passed by the two systems of grooving the bushings. The bearings are the same as those used for the test of increase of temperature with time of running, showing that the lower temperature is due to the larger amount passed with the central, circumferential groove

There are several factors, the size of the shaft and length of bearing, the load, the speed of revolution and the viscosity of the oil. For any particular case, all things being settled except the load, we can find a maximum load which will just be supported without breaking through the oil film at the point of smallest clearance. Taking the same conditions but putting the oil *supply* under pressure, we gain an effect equivalent to an increase in the strength of the oil film, allowing a higher load to be carried before breakdown in the film takes place.

There have been many learned works on lubrication and many long series of experiments, but these all serve only to give an indication of what may be going on in an automobile engine bearing. Nearly all the experiments have been made with large bearings running under constant loads, and the load in an automobile engine bearing varies constantly. Variations in cylinder pressure, coupled with the inertia effects of the reciprocating parts, cause perpetual variations in the oil film conditions. It is thought by most investigators

that this is of great assistance in maintaining the film. Suppose a load placed suddenly on the shaft, as by the explosion, it must take some fraction of a second to squeeze out the oil. By the end of this period the load is smaller or has changed its direction, thus offering relief to the oil film an instant before its fracture occurs, and the same thing is repeated throughout the whole cycle. Were it not for this, lubrication of a piston pin by splash would be utterly impossible. Here again the effect of having the oil under pressure can be seen, for it takes longer to squeeze out compressed oil than oil under little or no inherent pressure.

Another thing that is but little understood is the cooling effect of oil and its influence upon friction and the wear of bearings. In the sort of steadily loaded bearing with which experiments have been made there appears to be a definite oil temperature at which friction is lowest, but in these cases the only heat that reaches the bearing is the heat produced by friction. This is not true of an automobile engine, for this is kept hot and the 180 deg. or so in the water jacket is enough to maintain the crankshaft bearings at a fairly high temperature without the heat of friction.

Oil Cooled Bearings

Working on the assumption that lubrication will be assisted if the crankshaft is provided with more than ordinary methods for getting rid of its heat, A. P. Brush has devised his ingenious system of lubrication which uses the crankshaft itself as the main oil distributing channel. In this layout oil is pumped to an end bearing of the crank and led right through to the other end, small side holes giving the supply to the various other bearings. The idea is to pass through the crankshaft a much larger volume of oil than could be passed through the bearings.

No doubt in a splash system of oiling the oil which covers every portion of the inside of the crankcase carries off a good deal of heat as it drains back to the sump, thus using for cooling purposes more oil than passes the bearings, but there is one thing that must not be overlooked in considering the use of the oil as a cooling medium as well as for lubrication, and this is the ability of the oil in the sump to part with its heat to the atmosphere. The sum total in effect of supplying a bearing with a small quantity of *cold* oil might easily be the same as that of giving it an equivalent quantity of warm oil, using more warm oil to help cool it in other ways. If we assume that the oil, by some means, has to carry away so much heat from the bearings, we must provide the sump with means for transferring just that same quantity to the atmosphere.

Oil Radiators

In this connection it may be remarked that C. Y. Knight is reported to have wished, when designing the first Daimler engine, to pump the oil through external radiating tubes; possibly a few tubes in the water radiator could have been isolated for this purpose, but the Daimler Co. objected for fear it might be said that this was *necessary* with the Knight engine. In some racing cars oil radiators have been used most successfully, and in the short races at Brooklands a very usual trick was to have a big hand pump full of cold oil which could be shot into the crankcase about 150 yards from the finish, the result being a sensational jump in speed lasting just long enough to get over the line. This was in the early days and did not apply to modern machines with lubrication systems suitable for continued high speed work.

Another detail of lubrication which has had practically no attention is the grooving of bearings for obtaining the best distribution of oil. The few experiments made and reported go to show that most oil grooves do more harm than good. The reason for this is that the oil film is broken by the groove. Why this is can be realized when we remember that a groove connects different parts of a bearing and that the oil film pressures are different at different places. If we link two spots together by a groove we cannot easily maintain different pressures at the two ends, since the groove acts like a passage external to the bearing.

In a splash system the oil groove ought to run lengthwise of the bearing so as to carry oil nearly the full length, and the groove should be located at the point of minimum oil pressure. Here it will not interfere with lubrication, since the pressure will be the same for the whole length. Diagonal grooves are disturbing to the equilibrium of the oil. But there is a difficulty here, this being that the point of minimum pressure on the circumference of the bearing is changing every instant as the direction of load changes. This means that a number of grooves linked together may be better than a single groove, despite their drawback.

Need Only Central Groove

With forced lubrication, however, grooves lengthwise of the bearing are seldom necessary, since automobile engine bearings are short for their diameter. Experiments made by R. K. Morcom, the head of the first manufacturing firm in Europe to build high speed steam engines in quantities, showed that the power absorbed by a bearing was reduced as the quantity of oil passing was increased. This probably is due to two things, to the cooling effect of the extra oil and to the fact that a big flow forced through means that the oil film is thicker and the danger of its breakdown less. The result of Morcom's researches showed that the best form of oil groove where lubrication is under pressure is a shallow groove right round the middle of the bushing with no longitudinal grooves. The theory of the effectiveness of this is that it forms a reservoir of oil under pressure, and thus insures a direct supply at whatever point on the circumference the minimum pressure due to the load may happen to be least at any instant. The plain circular groove, however, has one disadvantage, this being that it will, after a time, provoke the growth of a ring on the shaft. To overcome this Morcom staggered the upper and lower halves of the groove, this giving essentially the same effect as the plain groove so far as lubrication is concerned, but removing any danger of uneven wear on the shaft.

The results of Morcom's work were summed up in a paper read in England as long ago as 1910, and most of the curves shown here are taken from that paper. It is rather remarkable that nothing of the same character seems to have appeared since, for Morcom admitted that his research could be carried much further. For example, he stated that the flywheel end bearing in an automobile engine might need a lengthwise groove as well as the central ring, in order to permit enough oil to be passed through, but the exact location of such an additional groove and its proportional dimensions have, so far as the present writer is aware, never been studied completely. There is no data available on small bearings under alternating load with different groove proportions and fed with oil under different pressures, and there is an opportunity here for some engineer with a good laboratory to do some most valuable work.

Cylinder Oiling Separate Problem

Automobile engine lubrication has been complicated terribly as a problem by the need for using the same oiling system for the bearings and the cylinders. The effect of the smoke trouble and of carbonization has been to cause lubrication systems to be designed for the cylinders rather than for the bearings, and this has perhaps been a factor in restraining proper examination of the subject *from the bearing viewpoint.*

Ideally we should design our lubrication for the bearings and care for the cylinders afterwards, but the presence of too much oil in the cylinders seems so very difficult to prevent that engineers have perforce given most of their attention to what ought to be a subsidiary problem. Thus any investigations that may be made ought to be independent of

the cylinders, for what we want to know is the facts regarding bearing lubrication. Once having these we can proceed to devise means for caring for the pistons.

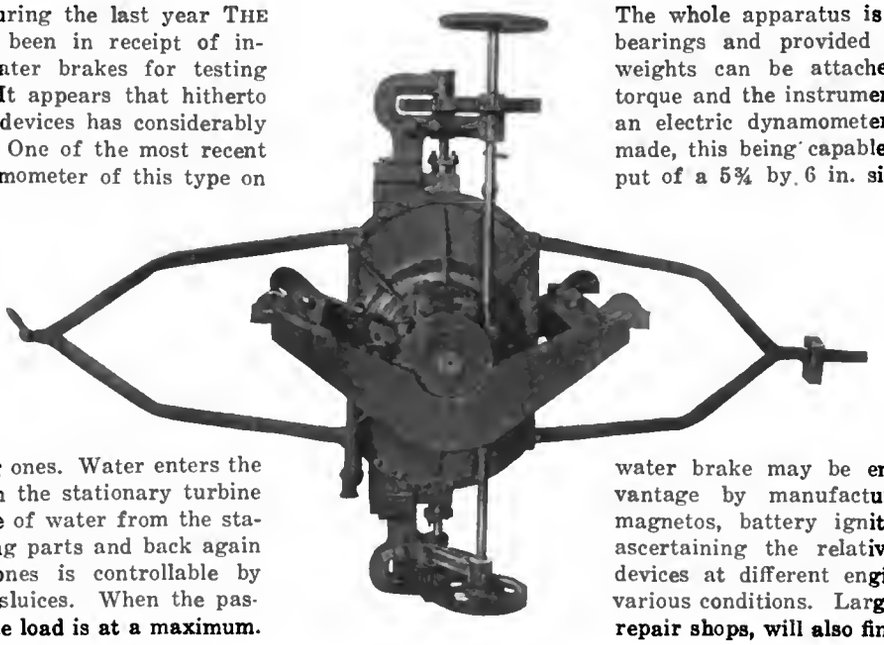
In discussion of an S. A. E. paper on a quite different subject, K. W. Zimmerschied questioned whether we might not some day come to thermostatic control of oil temperature. That we shall soon have an almost constant water temperature both winter and summer seems more than probable, so having thus removed one variable, it is not unlikely that Mr. Zimmerschied's suggestion for removing another may be followed out. If this is found possible in a commercial way it should be easy to discover by proper tests what pressure variations are desirable for the oil. Pressure, temperature and load are all connected in some way. To get the lowest bearing friction they must all be proportioned.

If the subject of bearing lubrication, here briefly outlined, waits the attention of a scientific investigation, there are other factors which are purely mechanical and do not require the same sort of laboratory study. One is the relation between size of pump and of oil leads to provide a desired flow at a desired pressure, and the other is means for keeping oil away from the cylinders. Since these matters are separate altogether from the theory of bearing lubrication, they are better considered as an entirely different subject, and it is the writer's intention to attack this phase in a subsequent article.

Herschell-Spillman Co. Manufactures Water Brake

Brings Out Device for Testing Automobile Engines

SEVERAL times during the last year THE AUTOMOBILE has been in receipt of inquiries concerning water brakes for testing automobile engines. It appears that hitherto the demand for such devices has considerably exceeded the supply. One of the most recent firms to place a dynamometer of this type on the market is the Herschell - Spillman Co., North Tonawanda, N. Y., maker of the Herschell-Spillman engines. The instrument consists of a double rotating turbine with two stationary members and two revolving ones. Water enters the brake through holes in the stationary turbine blades and the passage of water from the stationary to the revolving parts and back again into the stationary ones is controllable by opening and shutting sluices. When the passages are wide open the load is at a maximum.



The whole apparatus is mounted upon roller bearings and provided with arms to which weights can be attached in measuring the torque and the instrument is used exactly like an electric dynamometer. One size is being made, this being capable of handling the output of a 5¾ by 6 in. six-cylinder engine. It weighs 350 lb. and measures 8 ft., 2 in. from tip to tip of the two arms, as shown in the accampanying illustration.

Besides being useful for testing automobile engines, the Herschell - Spillman water brake may be employed to great advantage by manufacturers of carbureters, magnetos, battery ignition systems, etc., in ascertaining the relative efficiency of their devices at different engine speeds and under various conditions. Large service stations and repair shops, will also find it useful.

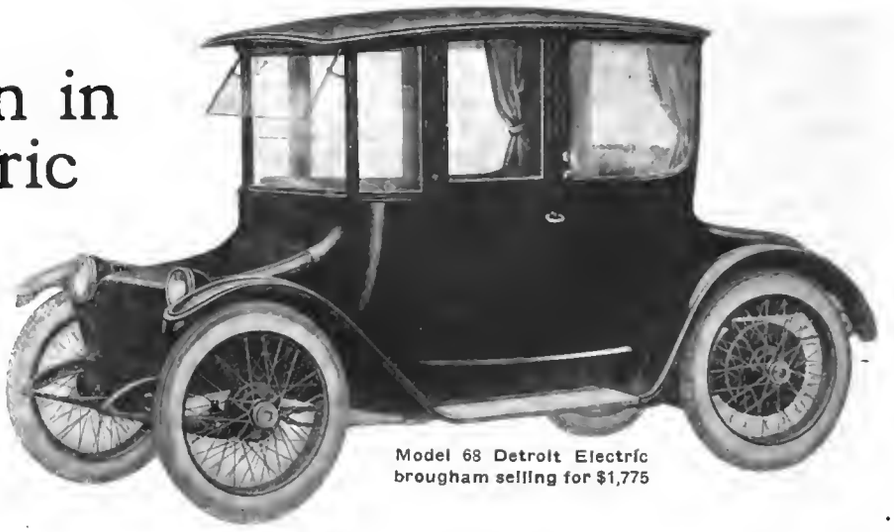
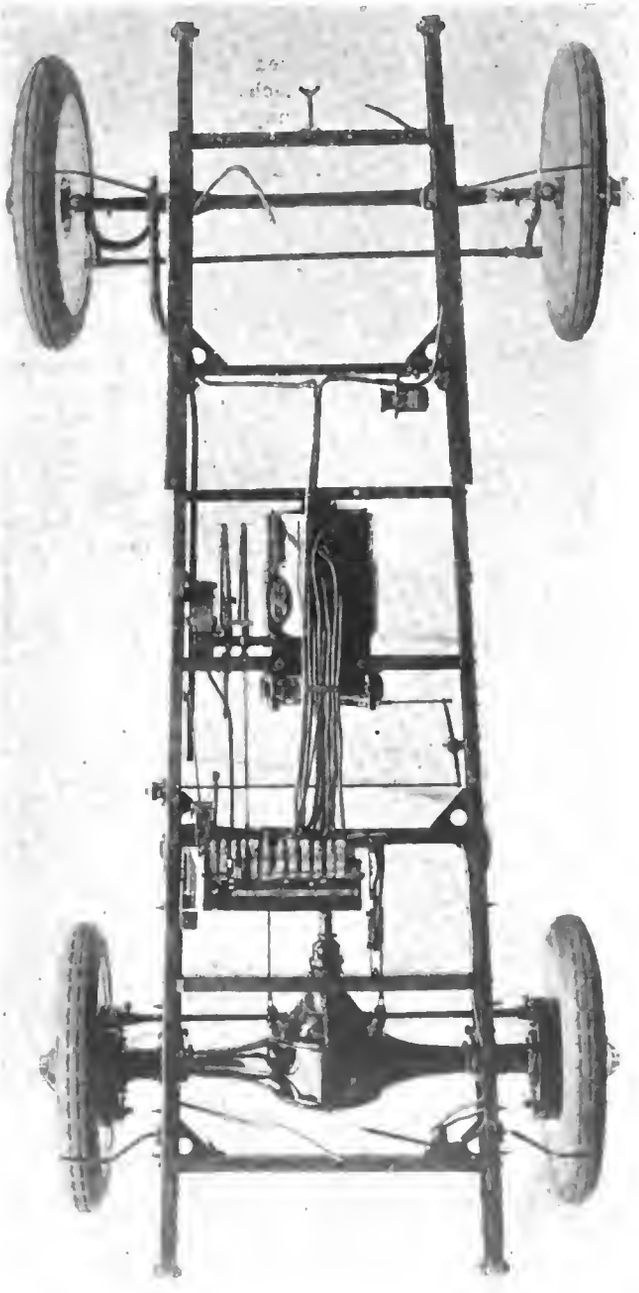
Standardization in Detroit Electric

Car Lightened, Tire Size Reduced, and Spring Suspension is Changed to Semi-Elliptic



Model 68 Detroit Electric brougham selling for $1,775



Plan view of the chassis illustrating the motor mounting, controller set and layout of wiring

STANDARDIZATION and all that quantity production infers have resulted in a reduction of $1,100 in 2 years in the price of Detroit Electrics made by the Anderson Electric Car Co., Detroit, Mich. The cuts last year were from $600 to $725 below the former cost, and this year $500 additional has been taken off the selling price without lowering the quality of the product, but simply by applying the rules of scientific manufacture on a quantity basis.

The reduction in price has been made possible by increasing largely the supply of up-to-date automatic and semi-automatic machinery, by using the chain method of production and by standardizing the product through the elimination of a wide variety of options in color, upholstery, finish, etc. The only changes in the specifications outside of the fewer options are a reduction in tire size from 34 by 4½ to 33 by 4½, a change in the spring suspension from elliptic rear to semi-elliptic all around and a reduction in the size of brakes and some of the dimensions due to the elimination of considerable overweight in the construction of the body. In spite of the great reduction in price this year, from $2,275 to $1,775, there was no apparent difference in the exterior of the cars with the exception that the side lamps are eliminated on the new model and the running lights incorporated in the head lamps.

Two Chassis Models

The more expensive chassis is continued, thereby giving the Anderson company two chassis models in place of one last year. The leader, however, will be the new model which is known as 68 and which is the product that is being put out on a quantity basis.

One of the important changes which has lowered the price of the car and has made it lighter, giving a considerable advantage in mileage rating, is the use of leather roof in place of the sheet aluminum. Weight has also been saved by the use of Hotchkiss drive, in the semi-elliptic spring and in the smaller wheels which have, however, the same section diameter of tire. The difference of weight is reflected in the smaller battery which is a forty-two-cell, thirteen-plate in place of a forty-two-cell, fifteen-plate which gives the same mileage as in the more expensive model. Some of the details on the new body are weight savers also, as they are in the line of greater simplicity. A good example of this is in the rear corners of the body which were formerly equipped with windows, while in the model 68 these are not installed.

Pressed Steel Used

Pressed steel is used in the structural work on the model 68 chassis, all the assembling being done in the Anderson factory. The cross members, brackets, and gusset plates are hot-riveted with automatic hammers to the side frame members. The cross members are designed to carry the electric

motor and the driving units which are assembled upon it. The motor is bolted to the frame in the center and the battery equipment is equally divided. Twenty-one cells of this are in front and twenty-one in the rear, giving a balanced car with the weight on the front and rear axles approximately equal.

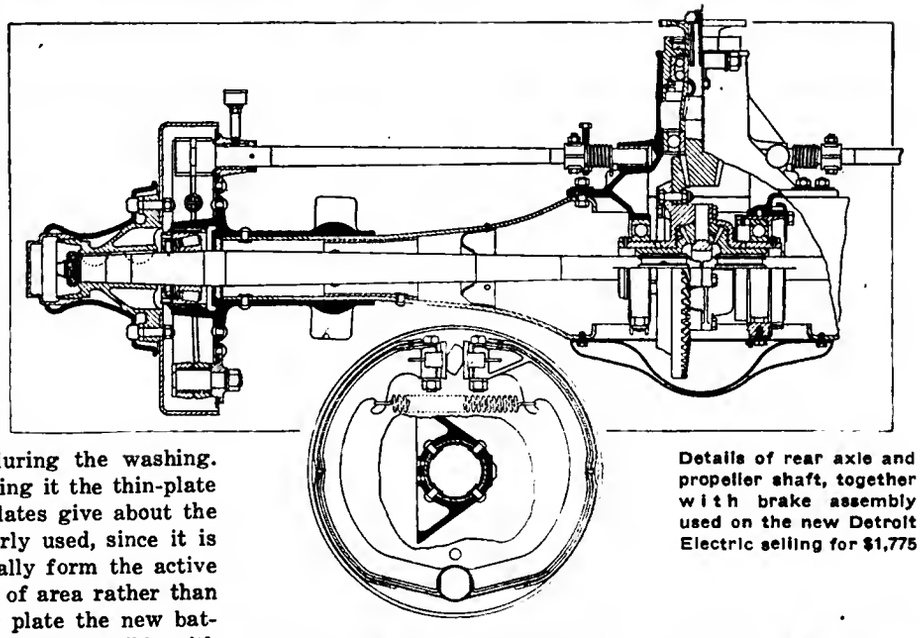
Wiring on Chassis

One of the assembly features of note is that all the wiring is made up in a standard form before it is assembled to the chassis by special cleats. The entire wiring with the exception of the body lights is carried on the chassis.

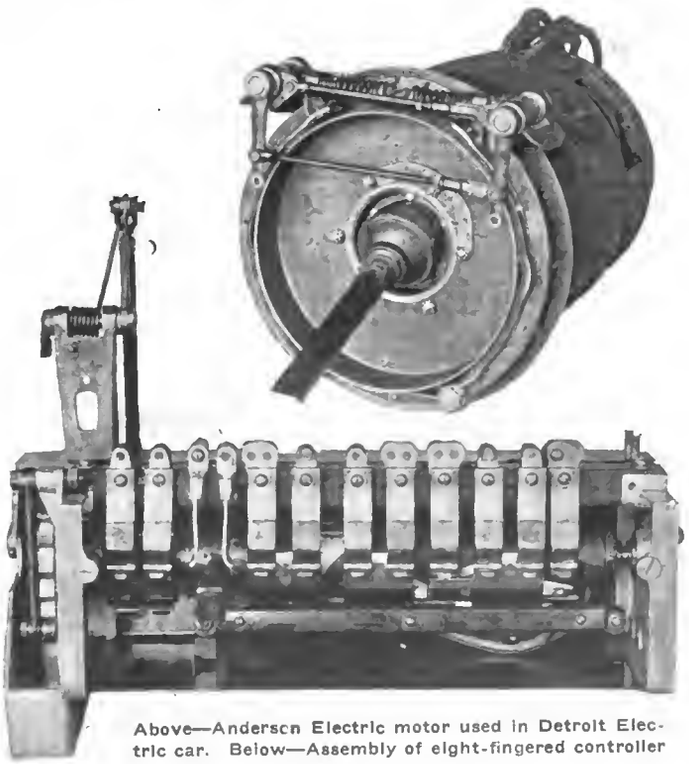
Timken bearings are used in the wheels with ball bearings for the steering parts and at the knuckles. The friction points in the majority of instances are equipped with self-lubricating bushings and the others with grease and oil cups accessibly located. The standard tire equipment is the Goodrich Silvertown cord.

High-ribbed jars are used in the new Detroit Electric batteries. These ribs are sufficiently high to hold all the active material which will come off the plates during their normal life, thus making a non-wash battery, or one that does not require washing. The purpose of this is to give the user more total life, as some of the active material is always lost during the washing.

Weight is saved in the battery by making it the thin-plate type. It has been found that the thin plates give about the same capacity as the thick plates formerly used, since it is only the surfaces of the plates which really form the active working parts and capacity is a question of area rather than plate volume. With the less weight per plate the new battery has a greater capacity per pound than was possible with the old construction. More plates can be placed in each jar, thus reducing the current used per plate and adding to the life of the battery. The Anderson company now guarantees a battery for 8000 miles or 2 years normal service. The capacity of the Model 68 with thirteen plates, six positive and seven negative, is 150 amp. hr. The battery is located under the hoods, front and rear, so that it is easily accessible for filling, etc. It can be removed by loosening the hold-down bolts.



Details of rear axle and propeller shaft, together with brake assembly used on the new Detroit Electric selling for $1,775



Above—Anderson Electric motor used in Detroit Electric car. Below—Assembly of eight-fingered controller

A series-wound motor of slow speed characteristics is used on Model 68. The feature of a series motor is that the torque increases with the load, and the electric car is thus enabled to increase its output to accommodate adverse road conditions. By using the slow speed motor, reduction gears have been eliminated with a saving of weight and an increase in transmission efficiency.

Motor 90 Per Cent Efficient

Hess-Bright bearings are used for the armature and as these are packed in grease they require minimum attention. There are four sets of carbon brushes distributed on a commutator of large area giving a high current carrying capacity. The efficiency of the motor is said by the Anderson engineers to be 90 per cent at normal running speed, this efficiency being obtained by using a large amount of copper.

Five speeds forward are supplied by the drum type of controller. This is a finger-and-blade design of large size to carry the heavy current resulting from overloads. As an additional safety precaution there is a self-lubricating felt oiler which rubs against the contacts on the controller, keeping them continually lubricated. Refinement of design has cut the number of fingers on the controller to eight, and this, together with the fact that the reverse switch aud cut-out switch are both mounted in the same housing as the con-

troller, has added simplicity and reduced weight. The controller is assembled underneath the rear seat and is covered by a dust-proof housing.

For the main circuits No. 1 wires are used and all the leads are short, as the motor, controller, cut-out and reverse switch are close together. In assembling the wires taper terminals are used sweated to the wires. These terminals fit into taper sockets and are screw-fastened.

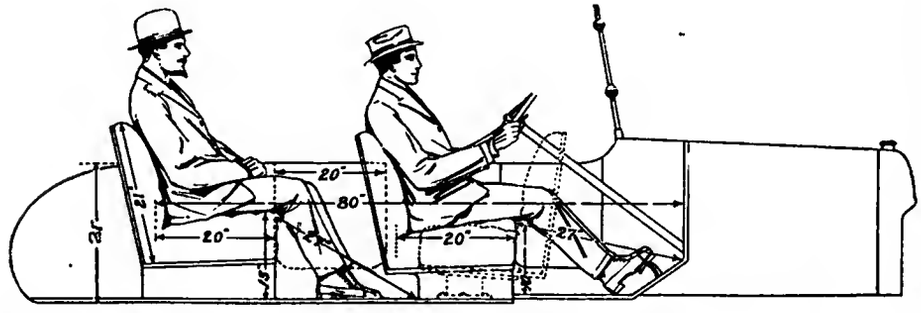
Direct drive through a short propeller shaft with two universals transmits the power to the three-quarter floating axle, the drive being through spiral bevel gears. Two separate sets of brakes are provided, those on the rear hubs being internal expanding, 16 by 2½ in., and these are operated by pedal. To the left of the brake pedal is a small pedal, pressure on which locks the hub brakes and automatically cuts off the power. This is for use when parking the car. The second brake operates on the motor and is applied by a slight backward movement of the control lever so that the motion for shutting off the power and applying the brakes is continuous.

In controlling the car, the operating levers are mounted at the side of the rear seat, in parallel position, one above the other. The longer lever is operated by the right hand and is for steering the car. The shorter lever controls the speed. When the driver leaves the car these levers may be turned up out of the way and locked, preventing theft. Speeds of from 6 to 25 m.p.h. are available, and the mileage per charge is between 75 and 100.

In finish and equipment, the electric brougham affords a vehicle of fine appearance. The fenders are pressed steel, oval-crowned designed and are skirted to the body, protecting it against mud. The standard painting is cobalt blue with white stripes. The wheels are painted in white, cream, red or blue, as specified. The upholstery offers a selection of three designs of whip-cord. It is Turkish type with deep cushions padded with curled hair. With the 100-in. wheelbase chassis a capacity of four passengers is provided.

Body features have always been carefully looked after in electrics and the new Detroit incorporates a number of comfort features. There is an upholstered package box in the left front corner which may also be used as a passenger seat. In summer weather the windows may be lowered by a patent device; and the door windows are sashless and are operated by a lever from the inside. The seat widths are generous, the rear seat being 49 in. with 18 in. depth, the door opening 24 in., and the distance from the front to the rear window, 63½ in. Houk wire wheels are furnished exclusively on this model.

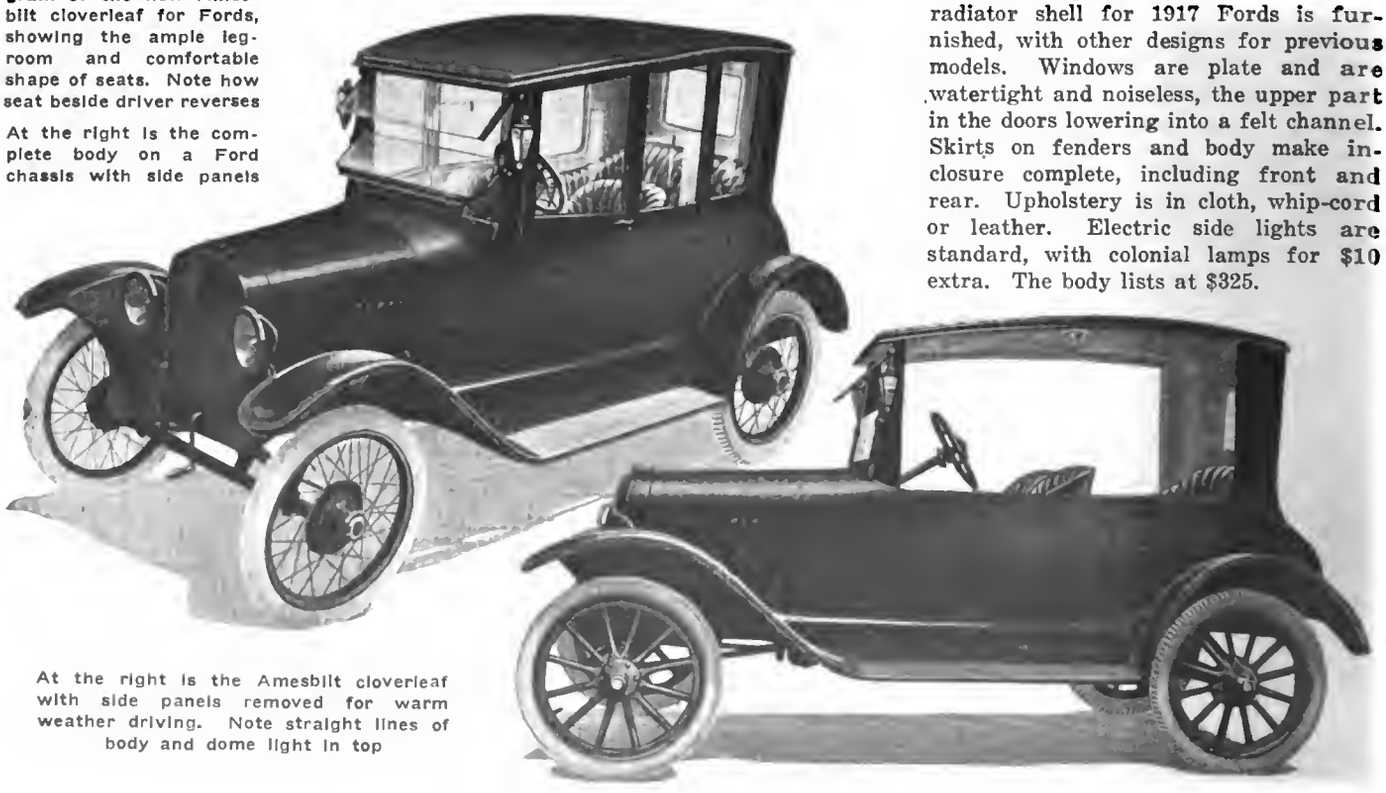
Amesbilt All-Season Cloverleaf for Fords



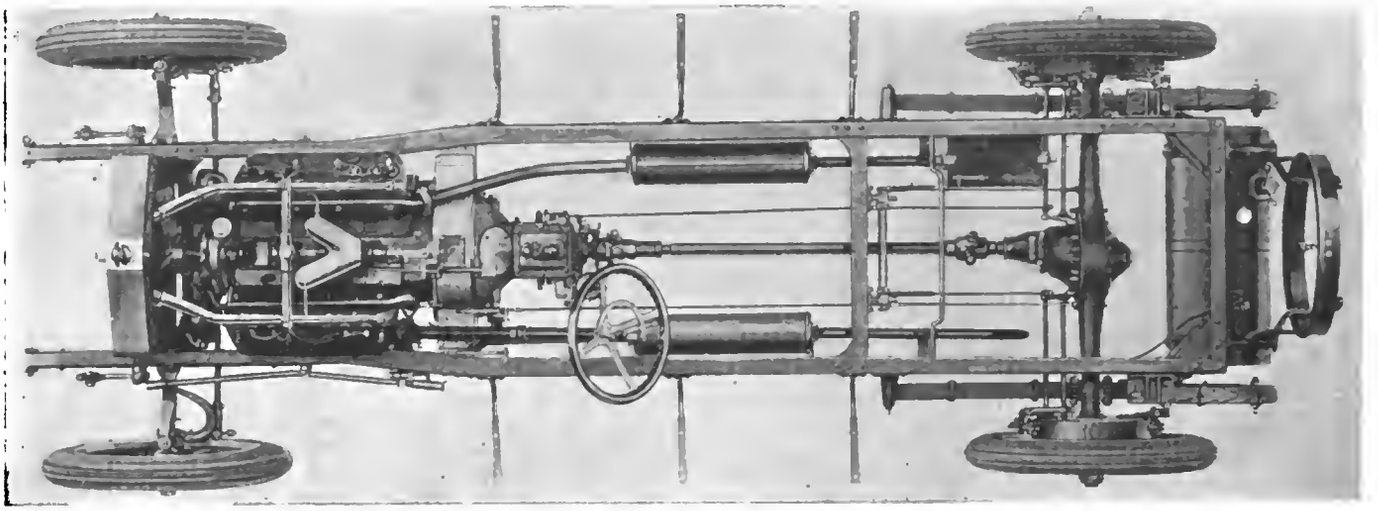
Above is a seating diagram of the new Amesbilt cloverleaf for Fords, showing the ample legroom and comfortable shape of seats. Note how seat beside driver reverses

At the right is the complete body on a Ford chassis with side panels

DESIGNED to render possible mounting an up-to-date streamline four-passenger all-season cloverleaf body on a Ford chassis, the Amesbilt construction illustrated herewith has been brought out by the F. A. Ames Co., Owensboro, Ky. As shown in the diagram, measurements have been arranged to provide ample leg-room and comfortable seating, the seat beside the driver being reversible without sacrificing rigidity. Top and side panels are removable but are securely fastened so that rattling is prevented. A special streamline hood and radiator shell for 1917 Fords is furnished, with other designs for previous models. Windows are plate and are watertight and noiseless, the upper part in the doors lowering into a felt channel. Skirts on fenders and body make inclosure complete, including front and rear. Upholstery is in cloth, whip-cord or leather. Electric side lights are standard, with colonial lamps for $10 extra. The body lists at $325.



At the right is the Amesbilt cloverleaf with side panels removed for warm weather driving. Note straight lines of body and dome light in top



Chassis of the Murray eight, showing the mounting of the unit power plant, position of storage battery, rear fuel tank and tire carrier and the layout of the double exhaust line

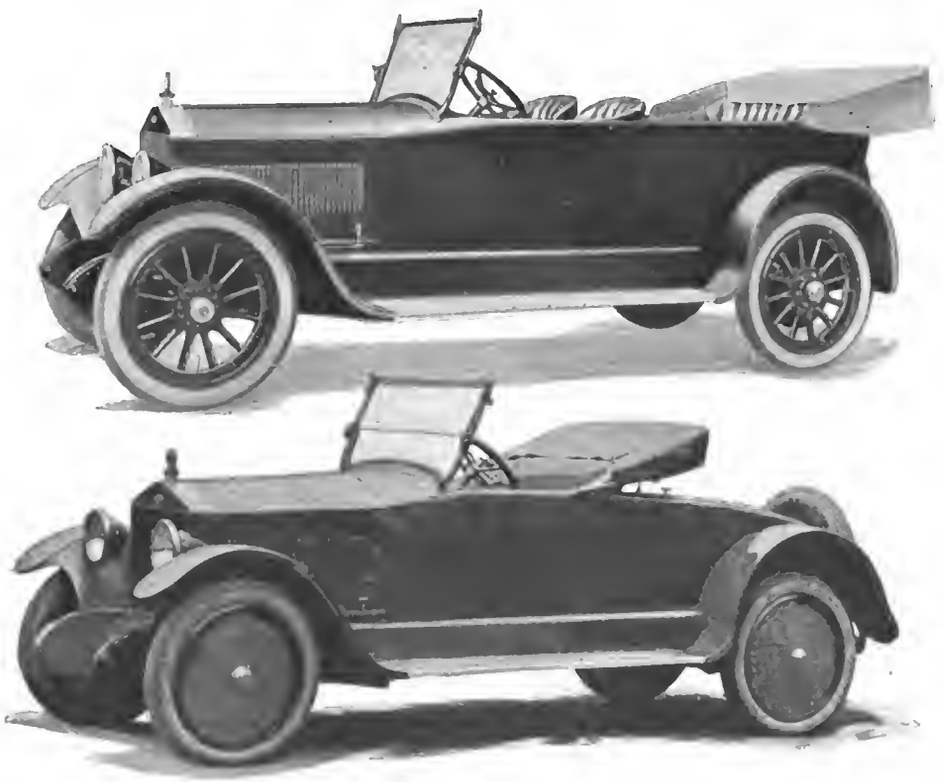
Murray Eight Has Custom Style

Standard Units Used in Substantial Chassis—Appearance Is Distinctive—Equipment Is Very Thorough

THE avowed aim of the Murray Motor Car Co., Pittsburgh, Pa., in designing the Murray eight has been to produce a car of broadly conventional design but with a distinctiveness of appearance and a general soundness of construction in excess of the normal. It is a powerful car and everything about it is after the custom-built style, the equipment being exceptionally thorough, and the price of $2,500 includes the option of finish in any color.

The power plant consists of a Herschell-Spillman engine, 3¼ by 5 in., which is claimed to have a b. hp. of 75, and a Covert three-speed gearset, the clutch being a Borg & Beck dry disk. The axles are both Timken, the floating pattern being used at the rear, and Hotchkiss drive is used, the rear springs being three-quarter elliptic. The electrical units include Westinghouse generator and starting motor with 100 amp.-hr. battery and ignition is furnished by a Dixie magneto.

Rigidity has been aimed at in designing the frame, which is of deep section, and it is dropped a little to give a low body position. The wheelbase of the chassis is 128 in. and 34 by 4½-in. Goodrich Silvertown cord tires are fitted as standard equipment. The smaller details of the chassis equipment include a Zenith duplex carbureter with a Stewart vacuum feed from a tank at the rear end of the chassis. The general equipment comprises every minor detail as well as such important features as an electric clock, a power tire pump, Hartford shock absorbers and a Boyce Moto-Meter.



Two body styles obtainable on the Murray eight-cylinder chassis for $2,500. The European influence is evident throughout the general design of both cars

Chassis Price $2,000

The chassis can be obtained without body for $2,000 and any sort of body is provided that may be called for, the illustrations showing a touring and a roadster obtainable for the $2,500 figure. It will be observed that the general scheme of the hood and body gives a European effect, making the car instantly recognizable.

Wheels are wood, of the artillery type, with the front wheels cambered, this constituting standard equipment, although wheels of other styles may be fitted.

The FORUM

Criticizes Vacuum Brake—Overlooks Important Feature

By H. M. Brayton

AS a student of mechanical engineering, I wish to submit the following criticism based on the article which appeared in THE AUTOMOBILE for Nov. 2, 1916, on the design of a vacuum brake for automobiles by the Prest-O-Lite Co. of Indianapolis, Ind.

The vacuum brakes designed by the Prest-O-Lite Co. seem to be inadequate to meet all the requirements demanded of a power brake for this class of work. Foremost among the faults of this apparatus is the fact that the brake is of absolutely no value unless the engine is running. It very often happens that the automobilist in descending a long grade, wishes to save fuel by allowing his engine to stop entirely. He could not do this unless his car was equipped with another brake and unless this vacuum brake will in itself cover all needs its field of usefulness must be very greatly reduced.

In heavy traffic where the surroundings are noisy it often happens that the engine will stop when the clutch is released and the driver be unaware of it. The brake would again fail with good chances for a smash-up and damages.

In the article mention is made that a difference of pressure of 10 lb. is available from the suction. I wish to show that in the average car with a volume ratio of 3 to 1 we have, assuming Boyle's law to hold and an isothermal suction, that

$$P^2 = \frac{PV}{V^2} = \frac{14.7 \times 1}{3} = 4.9 \text{ lb. absolute}$$

when P and V are the pressure and volume respectively, at the beginning of the suction stroke and P^2, V^2 the same quantities at the end of the suction stroke. This shows that the theoretical limit with this volume ratio is $14.7 - 4.9 = 9.8$ lb. difference of pressure available for the brake.

It is a well-known fact that gas engines nearly always exhaust above atmospheric pressure, and so it seems unlikely that the theoretical limit could be reached in practice. However, the lower pressure could readily be multiplied by leverage.

A cylinder 7 in. in diameter seems rather crude and takes up altogether too much space with this size, and a stroke of 4 in., the volume of which must be reduced in pressure before the full force can be exerted on the brake is very large and an appreciable time would be required.

The control valve is indeed an ingenious mechanism, and if the suction were only more reliable this brake would have a wide field of usefulness, especially in heavy work such as heavy touring cars and trucks.

EDITOR'S NOTE—Mr. Brayton appears to have overlooked the fact that this brake must operate as long as the gear is engaged and the car moving. When coasting with the clutch out if the engine stopped it would only be necessary to let in the clutch to obtain suction immediately.

Regarding the pressure available, running with the throttle shut in the idle position the pressure in the cylinder at the end of the exhaust stroke would not be above atmospheric. As to the size of the cylinder, this is by no means so large as a muffler and on most chassis there is plenty of room for it, since it can be mounted almost anywhere.

Melting Scrap Aluminum a Difficult Operation

THE melting of aluminum scrap, particularly chips from machine shops, might, to the uninitiated, appear a very simple process. How difficult it is to perform without excessive loss through oxidation is, however, made abundantly clear by Bulletin 108 recently issued by the Bureau of Mines. This bulletin has eighty-eight pages devoted entirely to this matter. The book is very interesting reading even to an engineer not too closely acquainted with foundry practice and in it, in addition to much very valuable information, there are some interesting figures regarding the quantity of aluminum absorbed by the automobile industry. It is stated that a conservative estimate of the amount of aluminum employed in automobile manufacture in the United States from July 1, 1914, to June 30, 1916, was 50,000,000 lb.

The percentage machined off from a rough aluminum casting in the finishing process seems, from data obtained by the writer, to average about 15 per cent, a figure which is much higher than was estimated offhand by several people connected with the automobile and aluminum casting industries, whose guesses averaged 3 to 4 per cent. The writer's result was reached by weighing rough and finished castings at an automobile plant making a car in the $700 to $800 class, and by weighing rough and finished castings made for various other motor car manufacturers at an aluminum foundry, with the results shown in the accompanying table.

The results of the tabulation, which indicate that 15 per cent was machined off, were so at variance with the estimates cited that the matter was taken up with the makers of a car in the $2,000 class, who state that on that car there are used forty-seven aluminum parts which are machined, the total weight of the rough castings used per car being 166.19 lb. The loss per car in chips is 25.15 lb., or 15.1 per cent. The weights were taken on the average of a number of like parts, in some cases as many as fifty being weighed. On the basis of 15 per cent of metal machined off, the yearly production of chips from aluminum castings in the United States will then run between 3,000,000 and 3,750,000 lb. If 20 to 30 per cent of this amount is unnecessarily lost, then 600,000 to 1,125,000 lb. of aluminum alloys worth 16 to 25 cents per pound, based on the average market quotations in normal times, is lost.

PROPORTION OF METAL MACHINED-OFF ALUMINUM CASTINGS

Casting	Weight of Rough Casting, Pounds	Weight of Finished Casting, Pounds	Percentage of metal machined off, Per Cent
Gear and transmission case	28.50	24.50	14
Small double-flanged exhaust elbows	.42	.35	15
Intake pipe for six-cylinder motor	5.00	4.80	4
Gear case for small motor	8.90	7.00	21
Gear case for very small motor	1.58	1.50	5
Crankcase for eight-cylinder motor	94.00	80.00	14.5

Self-Oiling Bushing's Many Uses

Automobile Industry Will Employ 5,000,000 During 1917

PROBABLY few people are aware that the impregnated self-lubricating bearings which are now used so extensively for light duty parts in automobiles are quite an old idea. Probably it is also seldom realized what a very large quantity of such bearings are now being used by the automobile industry. The Bound Brook Oil-Less Bearing Co., Bound Brook, N. J., will supply nearly 5,000,000 bearings of this sort solely for use on automobiles and trucks during 1917, this figure including the outputs of both bronze bushings with a special form of graphite insertion and wood bushings which are impregnated with graphite.

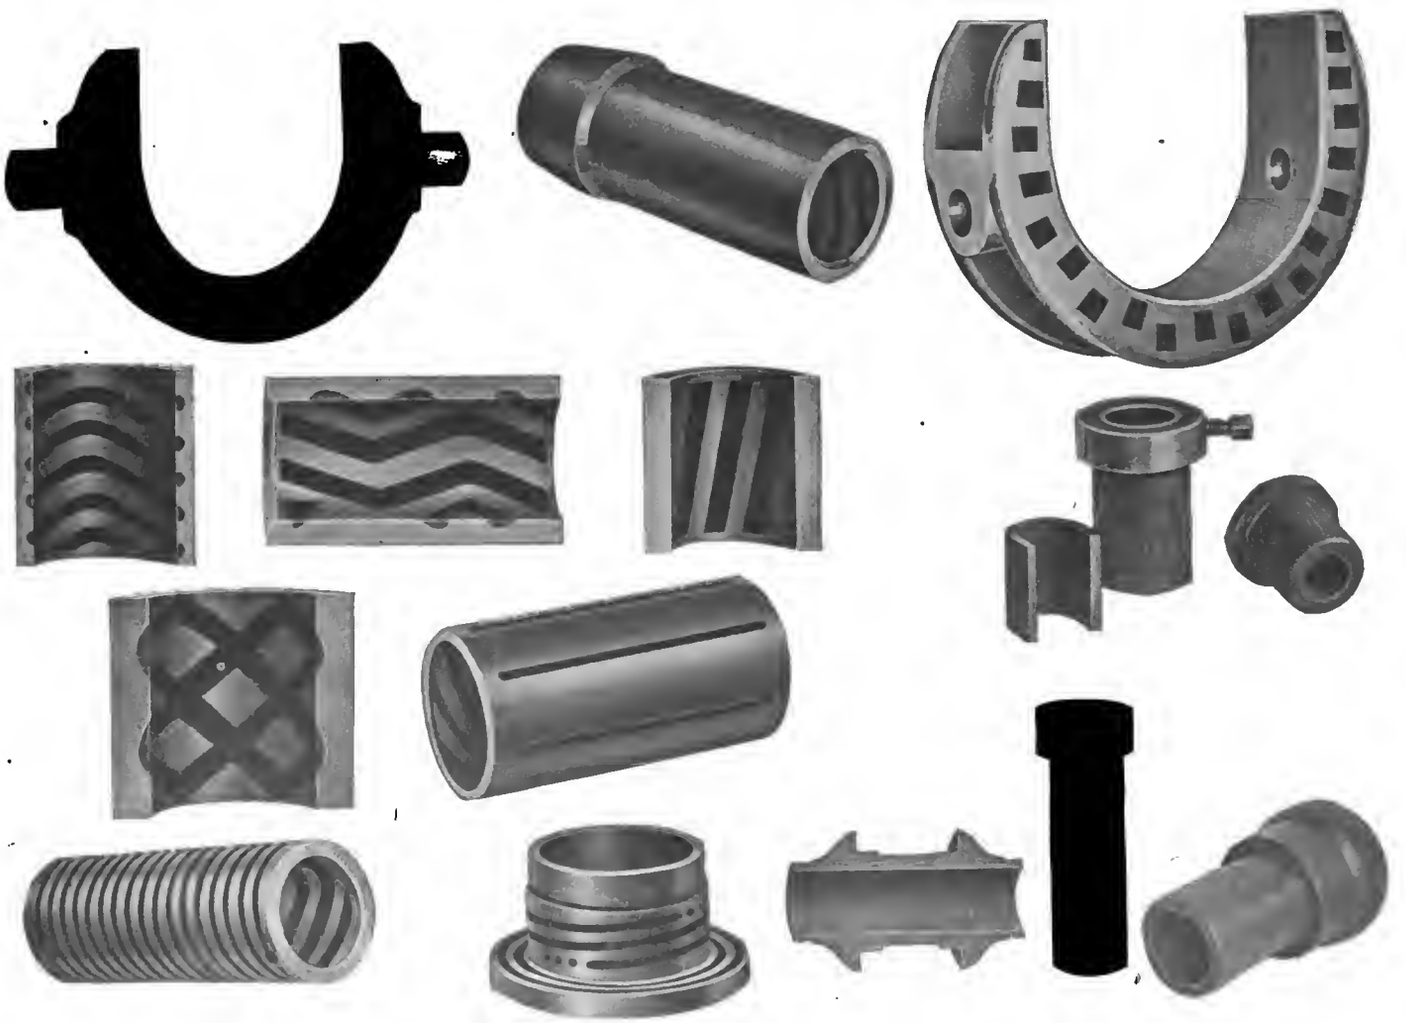
The original Bound Brook bearing was designed for use on electric trolley wheels, where the difficulty of lubrication was a serious trouble. The first batch of bronze bushings with graphite insertion was supplied for this purpose in 1889 and the output of trolley bushings alone is now in excess of a million a year.

Broadly speaking, the oilless bearing is valuable for two different classes of service. For parts with only occasional small motion, such as for the mounting of brake shafts, etc., a graphite insertion keeps the surfaces in good condition and provides all the lubrication necessary, continuing to do this for a very long time. It is even inadvisable to oil them because oil attracts dust, which it may transfer to the rubbing surfaces, while the graphite has no such tendency.

The other sphere of usefulness is in cases where a moderately light duty bearing will normally have a supply of oil, but may be allowed to run dry. A prominent example of this sort of application is the spindle of a starting motor. This is supposed to be lubricated but is often neglected. To use ball or roller bearings would be needlessly extravagant for a part of which only runs for such very brief periods. A Bound Brook bearing can be neglected even more carelessly than a ball bearing, because the latter requires to be protected from damp which would not injure the impregnated bushing.

Quite a different part which it is difficult to supply with oil or grease successfully is the thrust collar used for throwing out the clutch. Here again, we have an example of occasional use and the graphite inserted in the bronze is able to care for the lubrication unaided. Steering gears, pump shafts and many other applications will suggest themselves, and the illustrations give an idea of the many types of bushings made for automobile applications.

The wood bushing which is impregnated right through has a sphere of usefulness distinct from the bronze bushing with graphite insertion. Naturally the wood will not stand up



Bound Brook phosphor bronze self-lubricating bushings and clutch forks; the six pieces on the right are Nigrum wood bushings

under the same pressure per square inch that can be supported by the bronze, but wherever sufficient area is obtainable it can be employed because it may be oiled without producing any distortion. This probably is because the pores of the wood are completely filled during the impregnation, the bearings being finish-machined after that process.

Experiments in shackle pin bushing have shown that the wood is a much better material than the bronze, provided the spring eye is large enough to admit a bushing of such size that it will be certain not to split. Where movement is oscillatory and only over a very small angle, the graphite in the bronze bushings does not seem to spread very effectively; there should be a movement of something like 30 deg. to keep the bronze bushing in the best condition, but the wood bushing is not limited in this respect.

It is also highly probable that many uses will be found for Nigrum material, as this impregnated wood is called, in forms other than that of a cylindrical bushing; as an example experiments are being made with slip blocks on textile machines. The impregnated wood can be cut into any shape and the machining is cheap.

The process of manufacture of both the bronze and wood bushings is very simple. The wood is brought roughly to size and is then soaked in a solution containing graphite, after which it is subjected to a secret process, where fairly high temperature and pressure are applied simultaneously. After this treatment the parts are finish-machined and require nothing further done to them. The wood used is ironwood, this having proved the hardest wood that can be impregnated with certainty.

In making the bronze bushes, the grooves which are afterward filled with the graphite compound are cast, since some "tooth" is needed to hold the compound during manufacture. The bushes are finished completely before they are loaded, and to load them the bush is filled with a pasty mixture of graphite and a plunger is then driven through, forcing out the excess and ramming the groove. After this follows subjection to pressure and temperature, the details of which process are jealously guarded, this being followed by baking in ovens. The final process is to push through a plunger which removes any surplus lubricating compound and still further consolidates what is in the grooves.

Baker Steel Wheel Has Tension Spokes

INVENTORS of steel wheels are aiming at cheap production, good appearance, strength and convenience. The new Baker steel wheel seems one of the happiest combinations of all four qualities.

The raw material consists of a disk of thin sheet steel. The first operation is to punch out a number of pieces, so as to leave a set of spokes, joining the rim to the center. Then every alternate spoke is cut off at its inner end where it joins the center piece. This gives two sets of spokes, one set joined together at both ends, and one set with the inner ends free. The second set are then bent sideways and their ends riveted to a steel stamping consisting of a disk with a hub piece pressed out from it, the "hub" being welded or otherwise secured to the center of the original disk; and thus we have a complete wheel needing only the attachment of the rim. Any form of demountable rim can be used and any kind of hub design.

A special rim has been designed for this wheel, this being cut through at a point opposite the valve hole, and a turnbuckle used for contracting it, this being the only part that has to be unscrewed for detaching the rim; there are, of course, some studs or dowels to take the drive.

Plans are well advanced for the manufacture of the wheel on a large scale, both for passenger cars and trucks. The inventor is E. K. Baker, of demountable rim fame, and the patents are held by a new corporation, the Baker Wheel and Rim Co., Chicago.

Sketches showing the construction of the Baker steel wheel and a few variations upon the basic idea of the device

Lower Fuel Is Greatest Carbureter Problem

Increased Heat, Better Atomization and Higher Jet Velocities the Remedies—Few New Models But Many Refinements

By J. Edward Schipper

ONE consideration, the descending grade of fuel, stands out so prominently as an influence of carbureter design for 1917, that everything else is insignificant by comparison. Mechanically, every manufacturer of carbureters has a different solution for the problem. From an engineering standpoint, however, there are just three classifications of the methods used to meet the issue. These are, in the order of importance, heat, atomization and velocity. The latter two are correlated to a certain extent, but as will be seen by a study of the different types, there is a distinction.

There is a great amount of uncertainty, and has been for some time, regarding the matter of where the carbureter manufacturer ends and the car manufacturer begins in meeting the requirements of the heavy fuel. There is no doubt but that the problems of carburetion and intake manifold design are bound closely together. In fact, the best carbureter made will show poor results on an engine with an improper manifold. Hence the improvements which have been made by the engine and car designers in this respect have advanced the art of carburetion in its broad sense.

No Change in Fundamentals

A year ago, in its review of the subject of carburetion, THE AUTOMOBILE gave a complete classification of the types of carbureters used on American cars. The elapsed period has seen no change in these fundamentals; they remain the same, and yet it can be said that the art of carburetion has gone forward in the past year because the instrument is now coping with conditions which are far more difficult than they were then. The improvements are largely in detail. The details of manifold design, and of carbureter arrangement which have been improved all line themselves under one of the methods of betterment mentioned above; heat, atomization or velocity.

Manufacturers of cars demand from the carbureter manufacturer what the public demands of them. They are asking, in spite of the heavier fuel, for more acceleration, better and quicker starting on frosty mornings, better low-speed, high-gear performance, greater economy, lower idling speed, better hill climbing ability—that is, increased torque or crank effort at slow speeds with wide open throttle. In fact, everything that goes to make up good car performance is being demanded more vigorously every year by the car-buying public in every grade of car.

Classifying the Carbureters

The manner in which the desired result is attained forms the basic classification of the carbureter. This is really the starting point in carbureter design. The higher speeds, where the energy is at hand, are simple compared to providing an accurate, well broken up mixture at the lower end of the speed range. At the same time, this main jet, or primary device, which supplies the engine at low speeds, must play its part in the wider throttle openings. The ways in which this compensation is made have been classified as follows:

The air valve type, where compensation is made by the opening of an air valve.

The metering pin type, where compensation is made by raising and lowering a measuring pin which governs the jet size.

The expanding type, where the number of jets in action corresponds to the throttle opening.

The compensating jet type, where an auxiliary jet comes into action at wider throttle openings.

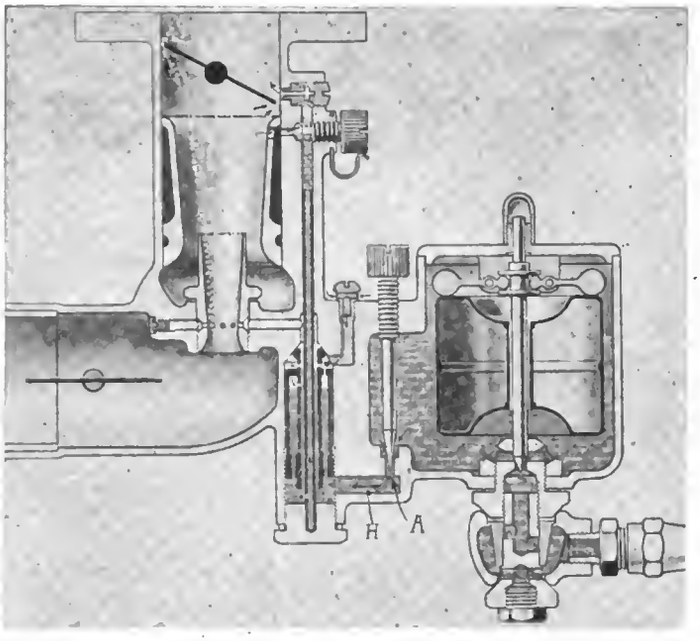
Besides these there are miscellaneous special divisions. As carbureters are classified according to these divisions, the well-known makes would be arranged under the heads in the accompanying table.

It will be noted that some makes, such as Stromberg and Rayfield, fall under different heads. This is because they do not purely belong to one class, but employ principles and are of such construction that they fall under more than one head.

This year engines are returning more for a unit of weight and for a unit of displacement than ever before. The carbureter manufacturer is playing an important part in this. The same elements that go to make for economy in carburetion go largely to make good rated performance in an engine. The manner in which carbureters generally have been improved in the lines mentioned differs according to the basis type of the carbureters. What representative makers have

Carbureters Classified

AIR VALVE	Heath	Ball & Ball
Air Friction	Newcomb	Tillotson
Breeze	Rayfield	Flechter
Zephyr	Tom Thumb	Sunderman
Shain	H & N	
K-D	Webber	EXPANDING
Browne		Master
Branford	COMPENSATING JET	Carter
Stromberg		Juhasz
Ensign	Zenith	
	Holley	MISCELLANEOUS
METERING-PIN	Stromberg	
	Longuemare	Stromberg
Schebler	Johnson	Rayfield
Stewart	Marvel	Kingston



In the new Stromberg model L a little mixture flows directly into the manifold above the throttle for starting and providing a good mixture when throttle is practically closed. A is the gasoline feed adjustment and H is the passage to the acceleration well through which the fuel passes from the float chamber

done forms an interesting study, the developments of each being taken up in detail on pages 1022 to 1031.

Stromberg Has a New Design

Stromberg has added an entire new carbureter to its line to take care of the dual problems set up by the higher demands and the lower fuel. In this new plain tube carbureter the general heads under which the improvements are found are atomization and velocity. The atomization is secured by introducing air into the fuel jet so that when it is drawn out it comes out not as raw fuel but as a partially mixed super-saturated vapor, which combines readily with the main flow of air.

The increased-velocity method is used particularly for high accelerative qualities and is used in connection with an acceleration well. When the carbureter is set for ordinary speeds at economy, as a general rule the flexibility has to be sacrificed to some extent. To overcome that the new Stromberg is so arranged that an extra supply of gasoline and air is supplied for acceleration when it is needed. The well fills with gasoline when idling or upon increased suction due to throttle opening, and in answer to the throttle demand this gasoline is drawn at high velocity into the main jet.

New Holley Uses Acceleration Well

A good example of the acceleration well is given in the new Holley. Under ordinary running conditions the well is dry. The well is formed by a bowl-shaped depression below a standpipe through which the mixture is drawn at high velocity. The air enters the standpipe through the bowl-shaped well space and the nearer empty it is the more air in proportion to the gasoline will enter, thus giving the compensation required.

These two makers, Stromberg and Holley, represent the only two who have so far carbureters of new type, and both have retained the fundamental features of their own designs. In practically every other case, the changes may be called refinements of existing types rather than alterations or additions of new principles.

Taking up the matter of acceleration, Schebler will soon be out with a new type, with low-grade fuel, which is one that is uppermost in the minds of carbureter and car makers alike. It will be worth while to note that in both the cases mentioned where marked changes have been made to attain higher acceleration, the acceleration well has been employed where the little supply of gasoline is held always ready to meet the requirements of the engine in picking up.

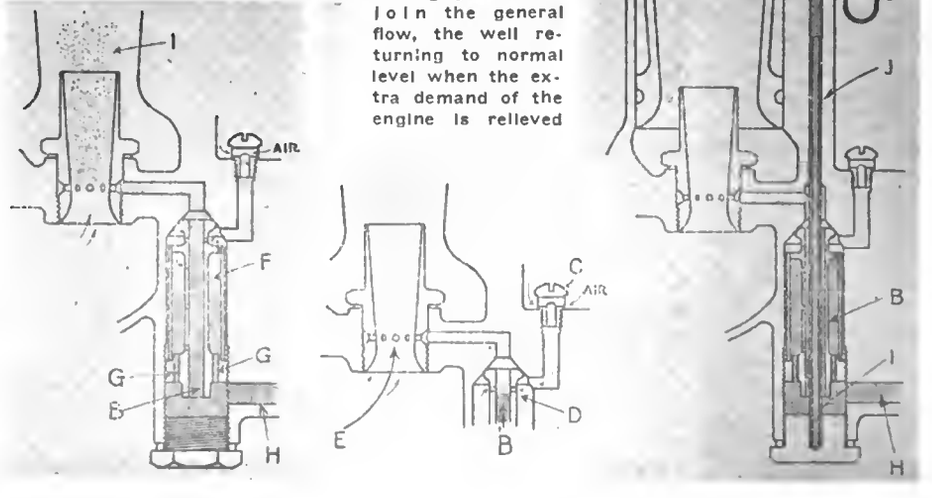
Full Hot Air Another Improvement

The use of full hot air rather than semi-heated air is another of the changes which are of use in increasing the accelerative qualities. The Master carbureter is an example in which full heated air is now employed instead of semi-heated, that is with primary air hot and auxiliary cold.

Another distinctive carbureter which should be mentioned in connection with improved acceleration devices is the Ball & Ball made by the Penberthy Injector Co. For easy starting and for acceleration there is a passage from the float bowl to a point above the throttle. This passage contains a plunger and when the vacuum increases it rises and shuts off the flow of gasoline from the intake passage. As the throttle is opened the vacuum in the intake passage is broken and the plunger drops, causing gasoline to gather above it. This is immediately drawn through the passage, giving the extra supply for acceleration.

The above examples are some of the special means taken to increase the accelerative qualities of the carbureters. It requires an additional flow and this must be instantly available or the carbureter will choke and sputter, before picking up its work. In the compensating jet type of carbureter this supply is given by jets uncovered by the opening of the throttle or which are brought into action in some other way by increasing the throttle opening. Carbureters such as the Master, in which the wider open the throttle is the more jets are uncovered, the Johnson, in which the suction raises a sleeve that covers the jet openings, and the Zenith, with a secondary jet surrounding the main jet, are all examples where the compensating jet takes care of acceleration. On the Zenith there is also a well, but this is used to supply

In the Stromberg L air enters at E, and through C and B, carrying fuel which is sprayed into the main channel. An accelerating well F concentric with passage B is filled with fuel. At speed air is drawn through C, forcing gasoline to join the general flow, the well returning to normal level when the extra demand of the engine is relieved



the secondary jet and is not open like that of the Marvel, Stromberg and Holley types.

Securing Easy Starting

The problems of acceleration and easy starting are somewhat allied, but differ in one material respect, and that is in the amount of throttle opening. When starting the throttle is nearly closed, when accelerating it is wide open. In both cases, however, a quick supply of gasoline is required, with a mixture richer than in ordinary running. For this reason on some of the carbureters the same device that acts for easy starting also helps in the way of acceleration. A good example of this is the Zephyr, which is a plain tube type of carbureter. A ball valve has been added at the bottom of the air tube and when the throttle is opened it causes a lag of the air behind the gasoline. A sudden throttle opening for quick acceleration will cause a spurt of gasoline to enter the intake, thereby enriching the mixture and giving the qualities necessary for acceleration.

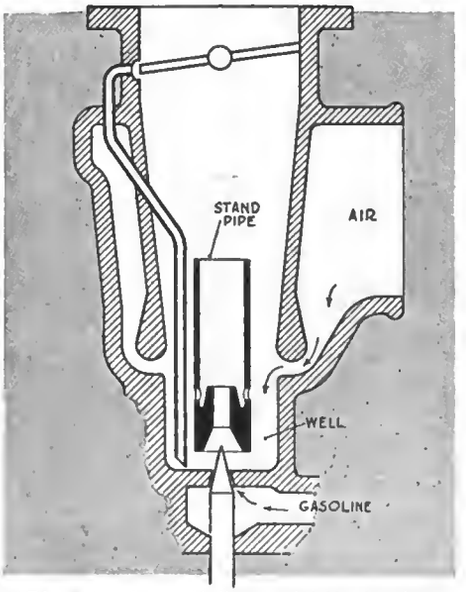


Diagram of new Holley model K, showing provision for feeding mixture direct into manifold above throttle for starting and low-speed work

This same device acts as a help for easy starting. When the engine is stopped the ball valve drops to the bottom, thereby cutting the air supply and causing the primary starting suction to fall on the nozzle and the supply of raw fuel needed is given.

As far as methods of securing easy starting are concerned there have been no innovations during the year. The majority of carbureter manufacturers have come to use an easy starting tube which connects the intake above the throttle directly with the float bowl. This provides the heavy mixture for idling as well as for starting. When the throttle is closed a high vacuum is created even at slow rotative speeds, and this vacuum falls on this easy starting passage taking in a flow of pure gasoline. There are several variations of this basic method used on the different makes.

New Air Regulation Features

Two trends in connection with the starting problem are noteworthy. These are in the increased use of dash controlled air, to help out the automatic devices used on the carbureter, and the use of an increased proportion of heated air. Both these are matters which are up to the car manufacturer as well as to the carbureter maker. The use of jacketed intakes and steering column and dash controls has increased to such a large extent that one carbureter maker, Marvel, has had to bring out a modified design intended particularly for cars with very hot intakes. The modification was made by taking the standard model E design and removing the exhaust-heated jacket. The new carbureter is called model F. It is provided with a full heated air intake and it is claimed that with a well-heated intake and this preheated air, the carbureter is particularly suited to the low grades of fuel now in use.

Low Speed Performance Problems

While the demands for acceleration and easy starting have been high, it is doubtful if they have been as difficult to meet as the low speed performance requirements. When the eights and twelves began to show 3 and 4 m.p.h. on high gear, with ability to accelerate from that speed advantageously, the makers and users of sixes and fours, regardless of the fewer impulses per revolution, demanded quite close to the same thing for their cars, and put the matter up to the carbureter manufacturer.

It has always been recognized that carburetion difficulties are great at low motor speeds, because of the lack of energy at the carbureter jet. The mixing of air and gasoline in the proper condition for combustion is, after all, a mechanical proposition. It means so much work done, and therefore must involve the factors of load and distance. The energy supply is provided by the vacuum or suction. It is utilized in breaking up the gasoline, in drawing in the air, and carrying the combined charge into the intake manifold.

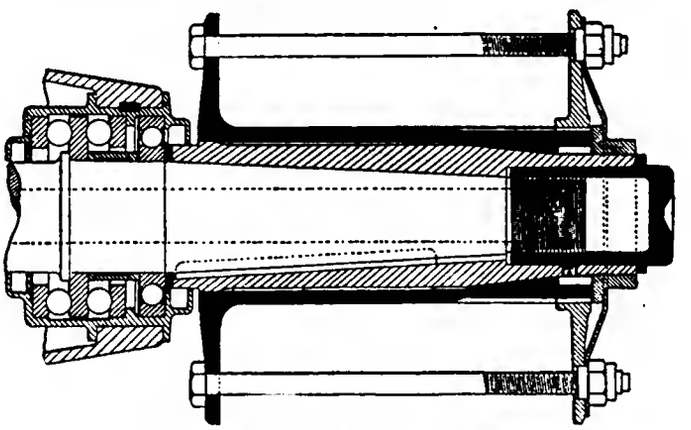
When an engine is turning over slowly the gas is not pouring into the cylinder at a high rate of speed, and naturally the kinetic energy necessary to break up the fuel is lower just at the time it is necessary to have the fuel well broken up to provide a good explosion for low speed work. By various means carbureters are arranged to give a richer mixture at these low speeds so that what air is drawn in will be thoroughly saturated with the gasoline vapor.

Elsewhere the different types of carbureters are discussed individually. The constructions of carbureters are in as many different forms as there are carbureters. The problems all have to meet are the same and the foregoing will show what these problems are and how, in general, carbureter manufacturers are meeting them.

A German Aeroplane Propellor Hub

THE Aeronautic Engine Division of the Standards Committee of the Society of Automobile Engineers has been devoting considerable attention to the design and possible standardization of propeller hubs. At the first meeting it was suggested by Howard E. Coffin that a quick-detachable device similar to that of the Rudge-Whitworth wheel might be used and shortly afterward almost precisely this idea was patented by the Rolls Royce of England.

The accompanying illustration shows an application made to the British patent office by a German company shortly before the war. It will be noticed that there is a bush secured to the shaft by a key and a nut and that the actual propeller hub fits over the bush. Driving is done by teeth cut on the outer end of the brush and on the inside of the hub. These teeth are tapered so that when the hub is locked into position by the securing nut there can be no shake.



A German design of aeroplane propeller hub

Few Changes in Carbureter Design

Four Fundamental Types Still Unaltered—Two New Carbureter Constructions—Principles in Use Are Greatly Intensified as Compared with Models of a Year Ago

INDIVIDUALLY, carbureters have not been changed materially during 1916. The four fundamental types described in THE AUTOMOBILE classification of a year ago still hold true. Up to the date of going to press there are two new carbureters which differ materially from the products of the same makers of a year ago, and even these are not changed in basic principle as much as in mechanical structure.

Along the line, however, there have been refinements which are more in the nature of intensifying the principles already in use rather than in the introduction of new ones. The increased demands of the public and, in turn the car manufacture, on one hand, and of the descending grades of fuel on the other, have made necessary alterations which carry out to an even greater extent the purposes which were clearly defined in carbureters a year ago.

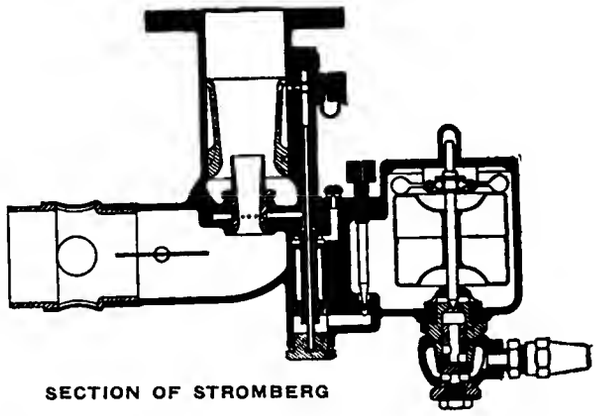
A greater amount of heat, a finer division or atomization of the fuel and a higher velocity of the mixture are the three basic improvements. All three of these can be traced directly to the heavier fuel to a greater extent than to the higher demands of the manufacturer, although both play their parts.

Three types of carbureter are almost equally popular. The air valve type, in which compensation for varying throttle openings is made by the air valve, has 28 per cent. The metering pin and compensation jet classes each have 25 per cent. The expanding type numbers 11 per cent, and the miscellaneous groups, which are not distinctively under any of the above heads has also about 11 per cent. There are some carbureter manufacturers whose products fall under more than one of the above classifications.

While the air valve type is numerically slightly stronger than any of the other classifications, the compensating jet class has gained two powerful recruits during the year. Stromberg is just adding a new carbureter of this type whereas its former designs were of the air valve class. There is also the new Holley which belongs under this head.

Differences in Stromberg

The new Stromberg compensating jet carbureter is a plain tube type, all air being preheated and taken through a straight, uninterrupted tube. It is made in both horizontal and vertical types and in style adapted to passenger cars, as well as constant load vehicles, such as trucks, marine engines and tractors.



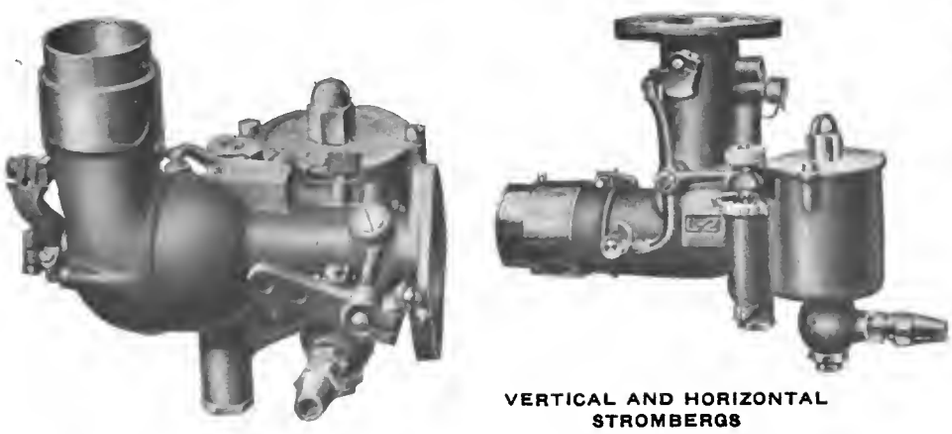
SECTION OF STROMBERG

The new plain tube carbureter differs from the previous types of Stromberg, particularly in what the Stromberg company calls an air-bled jet. In this the air is introduced into the gasoline before it emerges from the jet. The jet has a series of holes drilled around the throat of the venturi. There is also an arrangement for supplying a small quantity of gasoline above the throttle in idling.

Three features are incorporated in the new carbureter to meet the demands for easier starting, better idling, and acceleration with low grade gasoline. The first of these is the air-bled jet which consists in the introduction of a small, measured amount of air into the gasoline jet before it sprays out into the main air passage. This air forms a series of small bubbles which atomize the fuel and break the surface tension, causing it to flow readily at a low vacuum. The introduction of the air is dependent upon the suction in the manifold and thus the flow corresponds to the vacuum in the intake and is proportional to the air flow through the plain tube.

Referring to the sectional view of the carbureter, it will be noted that gasoline leaving the float chamber through a regulating orifice rises through a vertical channel, while air drawn in by suction through the protecting cap discharges into the gasoline channel or air-bled jet, breaking up the gasoline which issues in a number of small jets into the high velocity air stream in the venturi passage.

The second feature is the accelerating well. A small pool of gasoline is kept in communication with the main fuel passage so that at low throttle a supply of gasoline accumulates here and is held ready to supply the needs of a quick throttle opening for acceleration. When the extra demand is relieved, the gasoline in the well again returns to the normal level of the



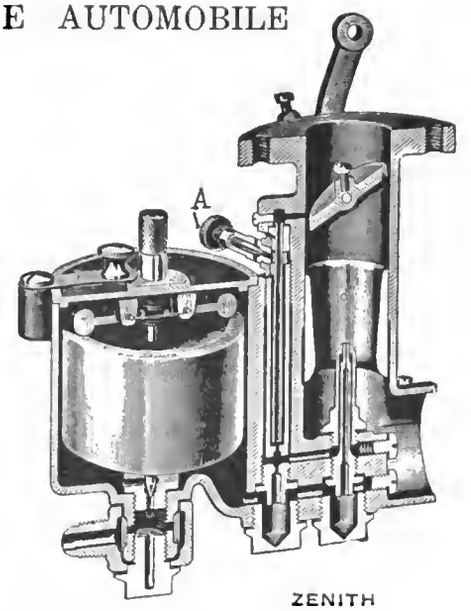
VERTICAL AND HORIZONTAL STROMBERGS

fuel in the float chamber of the carbureter.

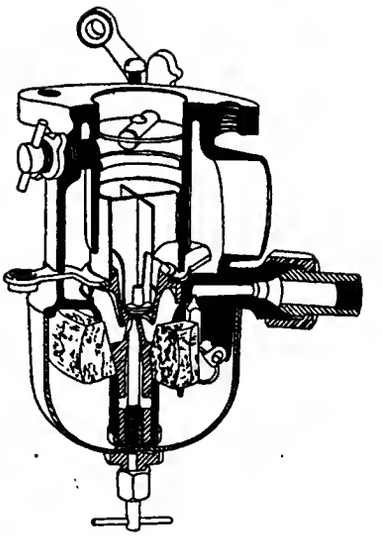
The third feature of the new Stromberg is its idling arrangement by means of which at closed throttle a small quantity of mixture flows directly into the manifold above the throttle so that the suction at idling speeds is sufficient to carry into the intake a column of gasoline from the float chamber.

Starting with fully closed throttle, the carbureter first draws gasoline from the small idling opening above the throttle. Then, as the throttle is opened further, gasoline is drawn from the main orifice into the venturi in the plain tube. At high speeds the air velocity through the venturi in the plain tube is so great that practically no fuel passes through the idling nozzle.

An economizer has been added to the Stromberg carbureter which is designed to produce a richer mixture needed for power at wide open throttle. This is a T-shaped part, having at its upper end a roller resting on a cam which turns with the throttle, and its lower end resting on a second cam operating the main air shutter. The horizontal portion of the T ends in a shoe upon which rests the adjusting nut, controlling the high speed gasoline meter. The shape of the cam on the throttle is such that the needle is raised slightly at closed throttle, lowered for ordinary driving positions ranging from 15 to 35 m.p.h., and raised again as the throttle is opened for speeds above this. A rich mixture for starting also is provided by cam on the main air shutter which raises the needle slightly, giving a rich mixture.



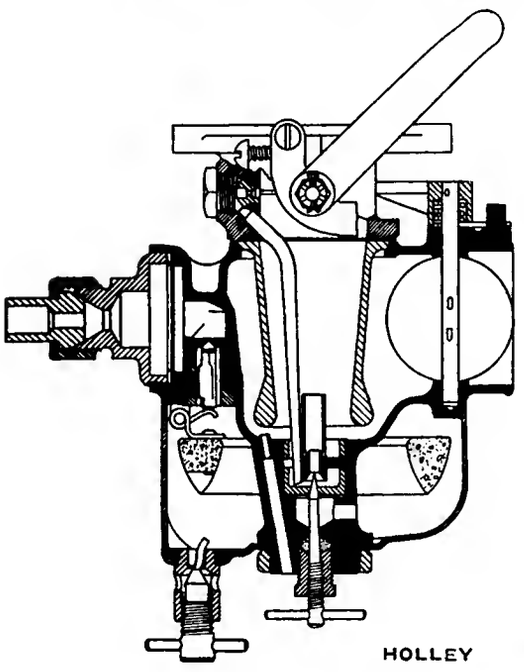
ZENITH



JOHNSON

New Holley Instrument

The new Holley compensating jet carbureter is an improvement over the previous Holley in that it has an increased capacity with decreased fuel consumption. The new model is known as K and the model G, Ford type, and the HA are continued without change, except for detailed alterations in the float mechanism, giving a better fuel control. The mixture flow is regulated by the vacuum at the jet, the intensity of which is controlled by the amount of throttle opening and by the varying positions of the actual air throat in the choke tube from which it is transferred to the jet by means of a standpipe, the constructional being shown in the illustration. The standpipe extends up from an accelerating well, in which gasoline lies in a pool for use when throttle is closed.



HOLLEY

As the throttle is opened wider, the gasoline does not have time to fill the well and hence a mixture of air and gasoline is taken up. The wider open the throttle, the greater the proportion of air, giving the compensation effect for high speeds. The only adjustment is the needle valve at the bottom which governs the flow of gasoline into the well.

The Ford type is the same as the above in principle but has no standpipe. It has, however, a well and all the Holley models have an easy starting tube which leads the gasoline from the well to a point above the throttle. There is also a dash-operated choke on the air line.

Zenith Unchanged

No new Zenith carbureters have been introduced during the past year. The models which are being continued over are L, O, HP and OD (Duplex). The only alteration on these is that on the Duplex type there are individual butterfly adjustments.

The flow in the mixture in Zenith carbureters is accomplished by regulation of the nozzle opening and by regulation of the air supply. This brings the carbureter into the compensating jet class. Uniform vacuum is maintained in venturi and elements depended on to secure vaporization of low grade fuel are, finely divided jet spray, high velocity and heat.

The carbureter has as a primary the fixed nozzle in the venturi. The secondary jet surrounds the primary and feeds fuel through the same venturi. The secondary jet draws its supply of gasoline from a well at the bottom of the easy starting tube. At idling speeds this tube is full of gasoline up as far as the level in the float chamber, thus feeding a rich mixture. At running speeds the gasoline in the tube is exhausted and the flow is sucked through the well passage into the secondary jet along with a supply of air. There is an idling adjustment on a needle valve and no other adjustments on the carbureter.

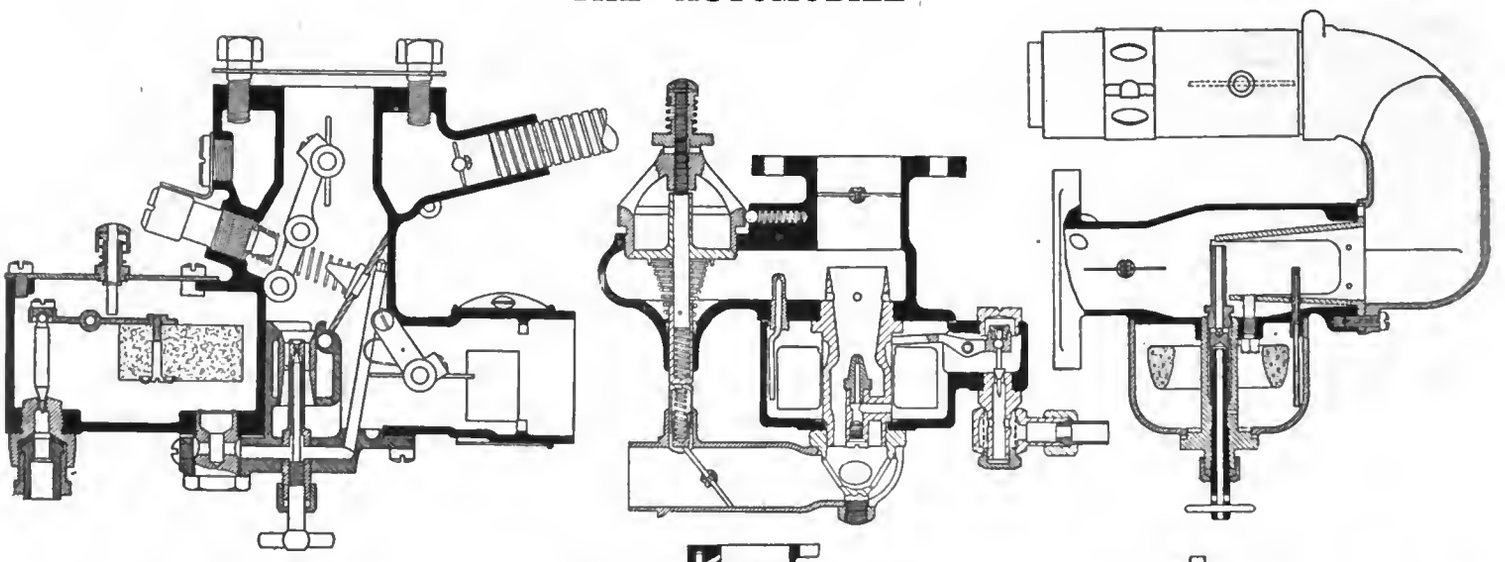
In buying Zenith carbureters the make and year of the engine should be known as the jets and choke passage must correspond. As in all carbureters the intake should be the same diameter inside as the carbureter. There are no special points in installation which do not apply to all carbureters.

No New Johnson Models

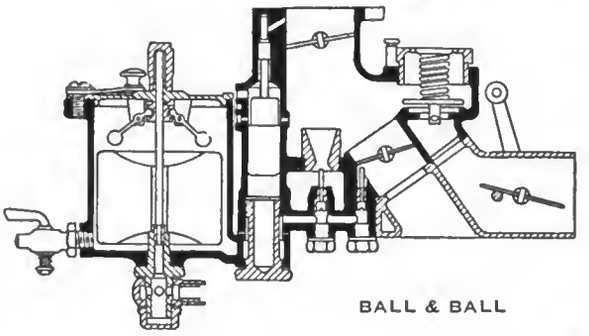
No new models have been added to the line of Johnson compensating jet carbureters. In this, the fuel flow is governed by an automatic sleeve air valve in a cylindrical mixing chamber. The cylindrical sleeve is concentric and carries a small plate at the bottom which regulates the jet passages and governs the mixture. In operation, suction of the engine raises the sleeve, allowing it to float automatically at the proper level to secure the correct jet area. There is a dash choke which rotates the strangling tube, shutting off all air.

Marvel Adds New Model

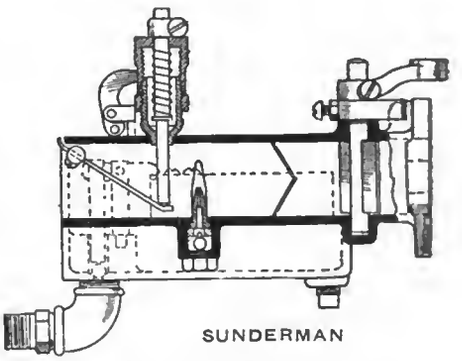
A new compensating jet model, known as F, has been added by the Marvel company. As far as the carburetion



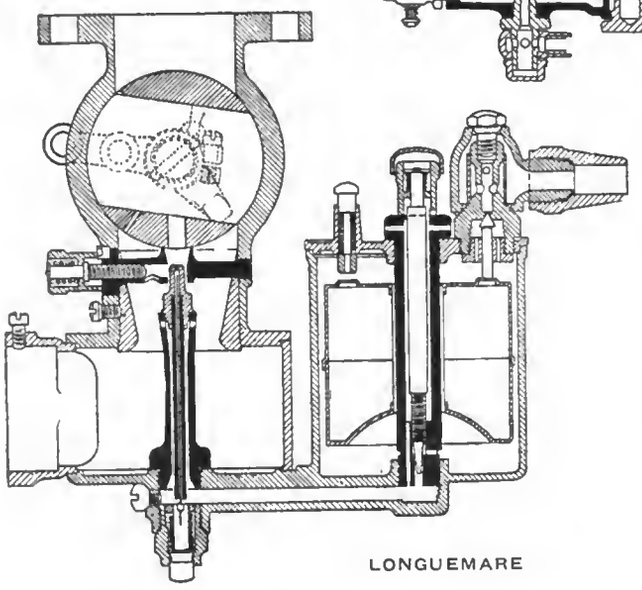
ABOVE FROM LEFT—MARVEL, FLECHTER AND TILLOTSON



BALL & BALL



SUNDERMAN



LONGUEMARE

elements are concerned this is the same as the previous model, E, but it is designed for engines with hot intakes and consequently it is made without the exhaust-heated jacket used on other Marvel carbureters. In addition to the new model, the standard model E and the model N Ford type have been continued with improvements. The alterations are in the nozzles, jets and air valves, which increase the velocity and at the same time atomize the fuel more finely. The fuel flow is regulated by an auxiliary high speed jet which is uncovered by the auxiliary butterfly air valve. The fuel is vaporized by the spray nozzle jet in the venturi and by the application of heat.

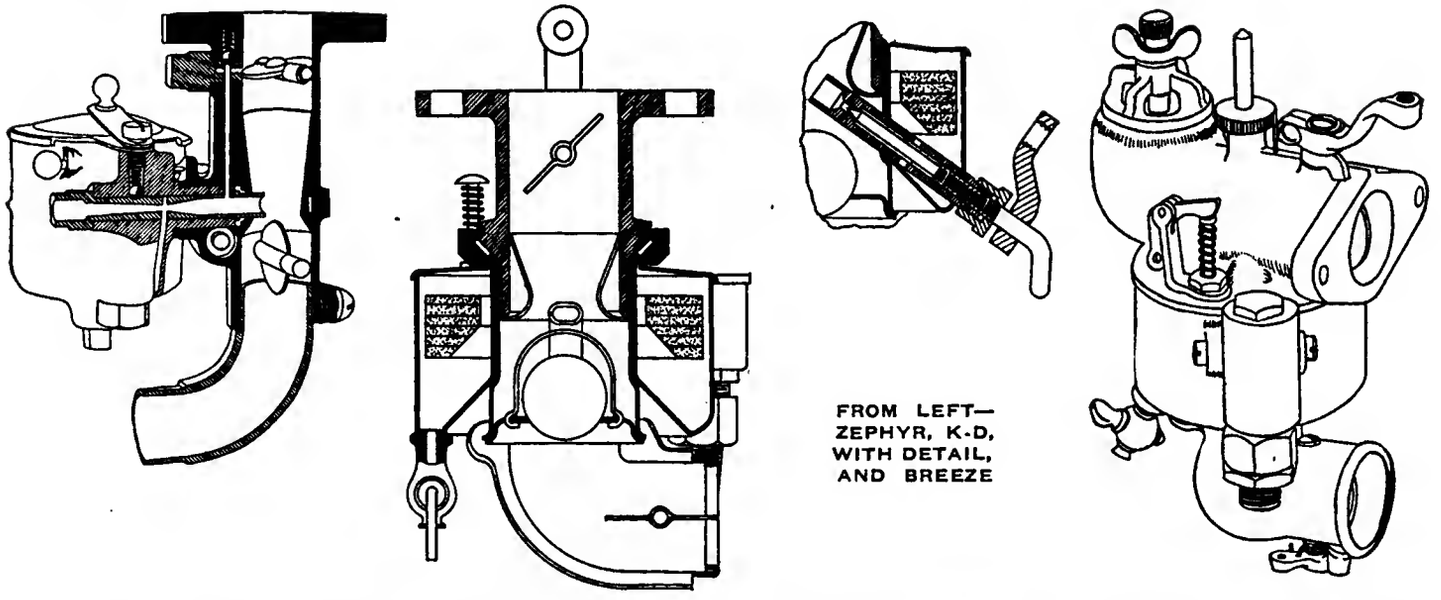
Ball & Ball Two-Stage Type

An interesting compensating jet model is the Ball & Ball, which its manufacturers call a two-stage instrument. It is really two carbureters in one, the primary being made up of a simple jet in a venturi passage. The second stage comes into play when the throttle is open and is made up by an independent air passage containing a separate air valve which uncovers the compensating jet. For easy starting, there is a passage which leads from the float bowl to a point above the throttle. In this passage there is a plunger which acts as a pick-up device. As the throttle is opened the vacuum in the intake passage is broken, allowing the plunger to fall and causing gasoline to gather above it. This is immediately drawn through the pick-up passage, giving the desired mixture for acceleration. There are no adjustments on this carbureter.

Tillotson, Flechter and Longuemare Unchanged

Three other carbureters, the Tillotson, Flechter and Longuemare, which are in the compensating jet class are unchanged. The Tillotson, which is known for its use on the Willys-Overland cars, has added a new model, however, which is simply the previous model B converted into a vertical type instead of being horizontal. In the Tillotson carbureters, a uniform partial vacuum at the fuel nozzle is maintained by means of two easy-yielding flexible reeds mounted on a cage designed so that the maximum opening takes care of the volume required to fill the combustion chamber at maximum speed. When the reeds are seated the primary nozzle supply is located in a small choke passage to give the highest possible vacuum at low throttle openings. The virtual effect of these flexible reeds is to give a variable venturi. only one air inlet is used so that a sufficient amount of heat is supplied for vaporizing the heavy fuel.

In the Flechter carbureter, the mouth of the venturi inclosing the main nozzle is carried up higher than the compensating nozzle. In operation the primary nozzle takes care of low speeds and when the throttle is open the auxiliary air valve drawn air passed the compensating jet. The latter leads into a well which is open to atmospheric pressure, so that at high speed air is taken through this jet, while at lower speeds gasoline also enters through it. This gives the necessary compensation.



FROM LEFT—ZEPHYR, K-D, WITH DETAIL, AND BREEZE

In the Longuemare, the main jet is shut off with closed throttle. As the throttle is opened the main nozzle comes into use and a further opening draws a mixture of air and gasoline through the supplementary nozzle. Thus, the compensating jet is directly functioned by the throttle.

Sunderman a Compensating Jet Type

Sunderman carbureters belong in the compensating jet class. There are two tapered nozzles at right angles to the air flow and the passage of the air past them creates a high vacuum directly at the nozzles. The mist thus formed is further broken up and gasified by passage through a screen.

In operation, as the motor is started, the suction raises the air valve which is held closed merely by gravity. The valve opens just sufficient to permit the air to sweep over the lower of the two nozzles. As the engine speed increases, thus increasing the suction, the air valve raises higher, thus bringing into play the second nozzle which is higher.

Air Valve Types Are Most Numerous

INCLUDED in the air valve types are the Zephyr, Air Friction, Browne, Branford, Breeze, Shain and K-D. Of these, alterations have been made during the year by Zephyr and Air Friction. The Branford, which at present is supplied only in the Ford size, will be made in all sizes after Jan. 1, 1917, without change in principle.

The air valve carbureters are probably the most simple of all types. Either automatically or mechanically an auxiliary valve opens at higher speeds, decreasing the richness of the mixture to take care of the needs of increased speeds. Primarily, the auxiliary air valve is necessary to relieve the vacuum at the main jet caused by the increased velocity of the air current. As engine speeds increase beyond 1000 r.p.m. the auxiliary air valve become necessary, and it was from this type that the inspirations for the more complicated automatic devices were drawn.

Zephyr Adds Ball Valve

The Zephyr is a plain tube instrument which has been refined this year by the addition of a ball valve at the bottom of the tube. The object of the change is to put more suction on the gasoline jet, thus securing better atomization of the heavier gasoline. The standard Zephyr type without the ball valve is being continued. A uniform partial vacuum is maintained by the venturi shaped air passage, through which the air flows at right angles to the main jet. In the new model the ball valve is seated at the bottom of the tube with a smaller air valve above it, so that primary air is taken above the ball and the auxiliary air secured by lifting the ball with the vacuum in the intake. The air through the primary opening is heated, and through the opening below the ball is cold.

The atomizer and jet runs from the float bowl into this air passage at right angles and the velocity of the air over the interior end of the atomizer creates sufficient vacuum within it to spray the fuel into the venturi-shaped mixing chamber. The atomizer has four different jet openings which line up with the intake from the float chamber. The adjustment is made by turning it until the proper opening is in line. There is also a throttle jet which is in the form of a tube running above the throttle, acting as an easy starting device and idling feed, on closed throttle. A starting shutter in the bottom of the air tube throws all the suction on the atomizer and insures a good starting mixture.

Browne Has Changeable Intakes

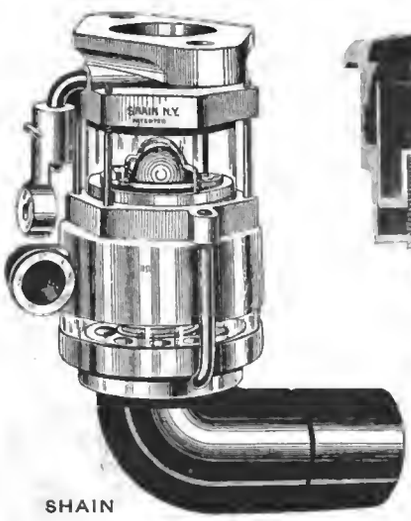
Browne carbureters belong in the air valve class though the air valve in this case is controlled directly by the suction in the venturi. The auxiliary air valve is an aluminum cup held on its seat by a spring and sucked open in proportion to the speed of the engine by the rush of air passing and opening directly opposite the fuel nozzle. Therefore, any change in the fuel flow automatically changes the quantity of air mixed with the fuel. The internal construction of the Browne is scientifically proportioned to the requirements of the motor. The size of the venturi and of the auxiliary air inlet is changeable, and is determined by the piston displacement of the motor.

Breeze an Air Valve Construction

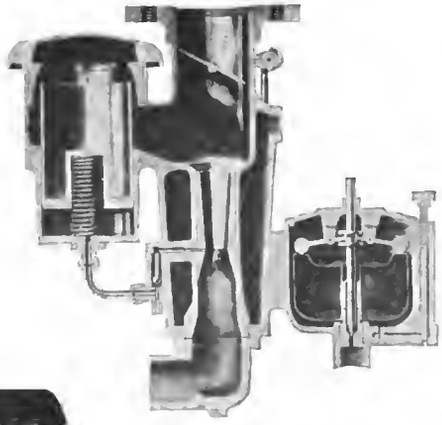
The Breeze carbureter is a simple air valve type. The incoming air passes through a venturi inclosing the fuel nozzle so that the suction determines the quantity of fuel drawn through the nozzle. As the mixture would be too rich at high speeds without the addition of more air, there is an auxiliary air valve controlled by a spring.

Air Friction Is Unchanged

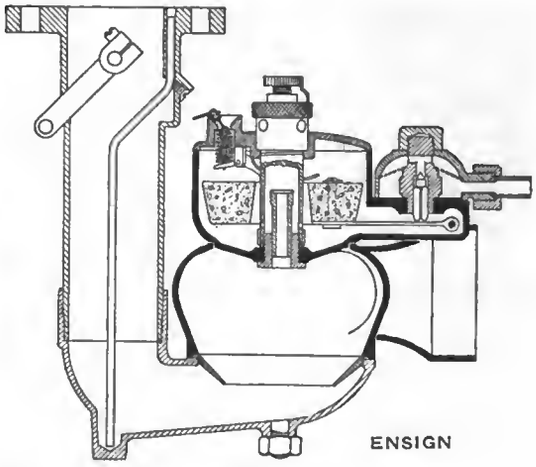
Air Friction carbureters are of the air-valve type in which the auxiliary air valve maintains the proper proportions of



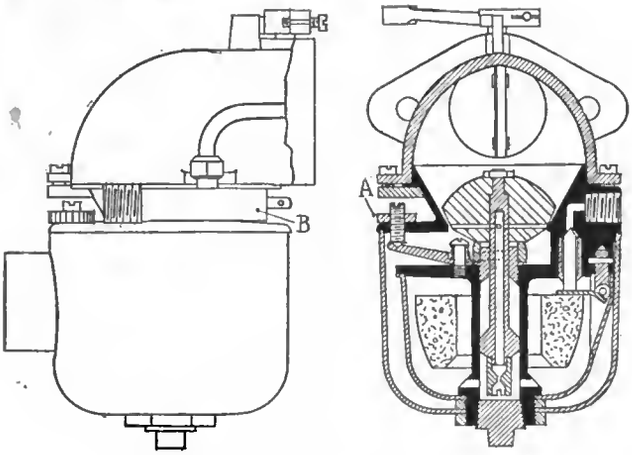
SHAIN



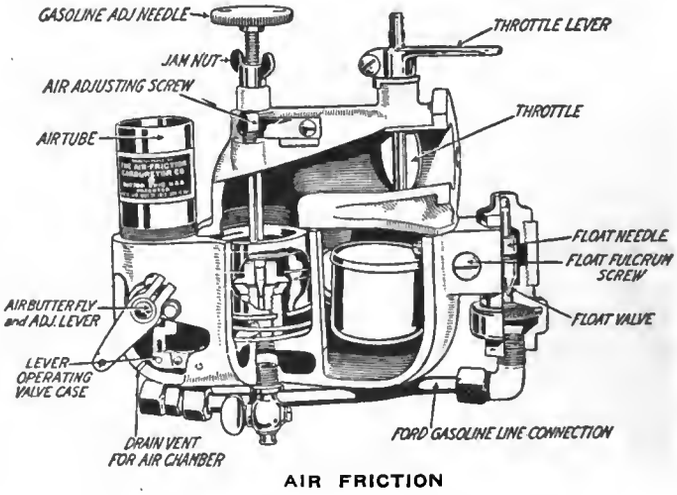
BROWNE



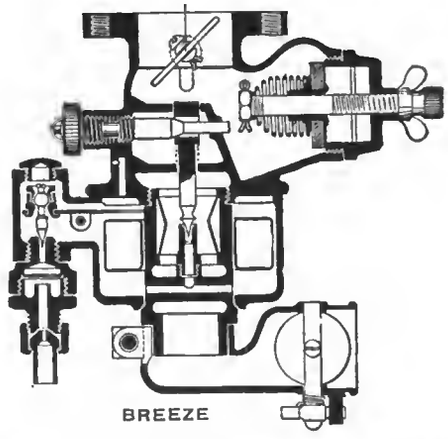
ENSIGN



TWO VIEWS OF BRANFORD



AIR FRICTION



BREEZE

gasoline and air. There has been only one change in this carbureter for 1917 and this consists in an improvement in the spray nozzle, holes being drilled in the lower collar.

K-D Has One Adjustment

Belonging in the weighted air valve class, the K-D is a simple instrument in which there is but one adjustment. Air entering the intake lifts a ball which permits the proper amount of air to enter the carbureter in proportion to the speed of the engine. As the air enters it picks up fuel from a single nozzle which projects into a venturi.

Shain Uses No Float

The Shain carbureter is a combination of weighted air valve single jet types. The jet is normally closed by a bronze ball which is raised off its seat by the rush of air thus permitting a certain quantity of fuel to mix with the air. There is no float, the ball over the jet preventing leakage of fuel when the motor is stopped.

In operation, the rush of air causes the ball to rotate and thus to throw out a thin mist of gasoline which is mixed with the air, which also is rotating, and thus passes on to the cylinders.

Branford Employs Constant Vacuum

The Branford carbureter belongs in the constant-vacuum weighted air valve class. The fuel is drawn up through the center of this weighted air valve and issues from orifices around the circumference of the valve where the velocity of the air is greatest. Inasmuch as the amount of fuel picked up is governed by the velocity of the air passing the fuel nozzles and the velocity in turn is controlled by the vacuum which remains practically constant, the quality of the mixture does not change with the change in volume required by the motor.

At present but one size for Fords is made but at the New York shows there will be on exhibit a full line operating on the same principle and intended for all makes of cars.

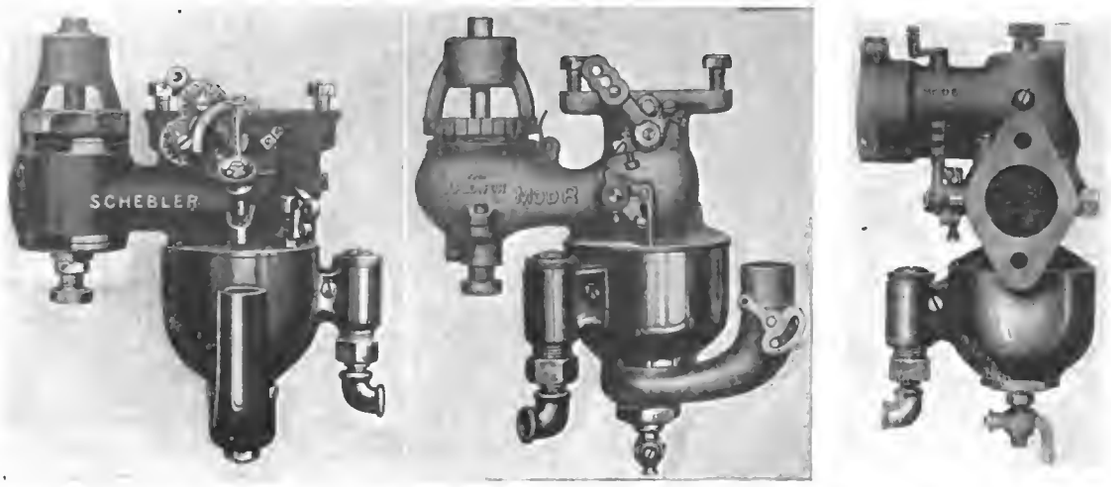
Ensign Is Different

The Ensign carbureter is radically different from anything else of the kind. The mixing chamber is directly beneath the float chamber. Air enters the mixing chamber and is converted into a whirling current which centers about the fuel inlet. Suction on the fuel inlet draws fuel into the air where it is thoroughly mixed. Admixture is assisted by the passage of the mixed gasoline and air through a constricted area before it enters the outlet to the manifold.

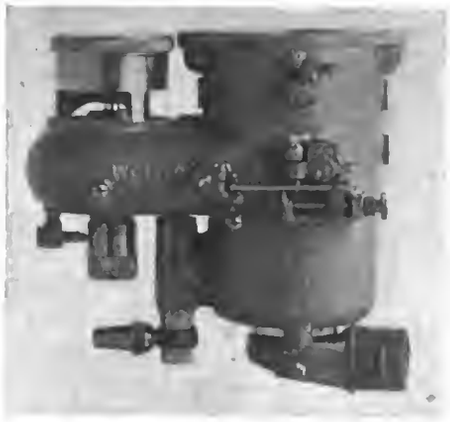
To permit the richer mixture required by extreme low running there is an unbalanced butterfly valve in the intake. This is horizontally placed and when the motor is idle hangs down so that the intake is partly closed. The slowest air movement causes it to shift its position so as to increase the amount of air admitted. It affects the working mixture only at extremely slow speeds.

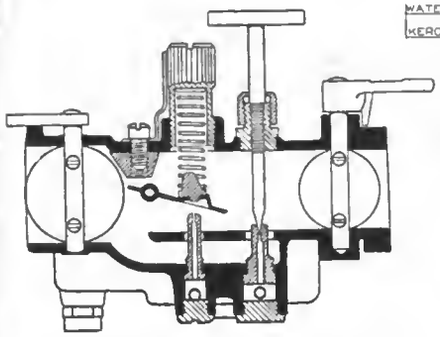
The carbureter is made in three types, for gasoline, distilate and heavier fuels and is made in all the usual sizes from 1 in. to 2½ in. varying by ¼ in. sizes.

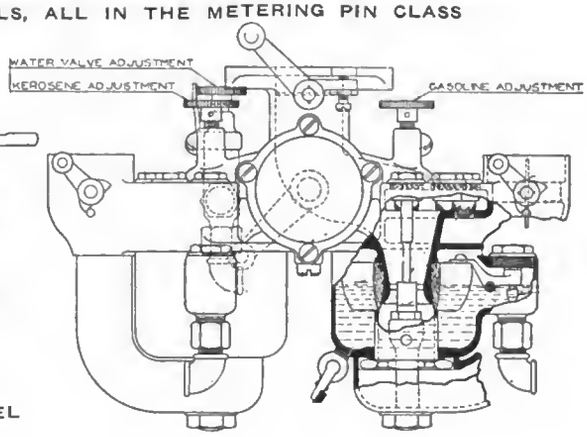
Some Standard Carbureter Designs



THREE SCHEBLER MODELS, ALL IN THE METERING PIN CLASS



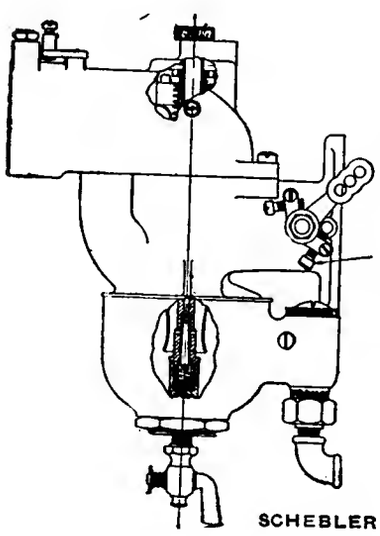




FROM LEFT, WEBBER, MARVEL AND KINGSTON

Carbureters of the Metering-Pin Class

SOME of the best known carbureters used on up-to-date cars are classified as metering-pin carbureters. They include such makes as Schebler, Stewart, Rayfield, Newcomb, H & N, Webber, Heath and Tom Thumb. In this type, the raising and lowering of a calibrated pin governs the size of the fuel opening in proper relationship to the engine requirements.

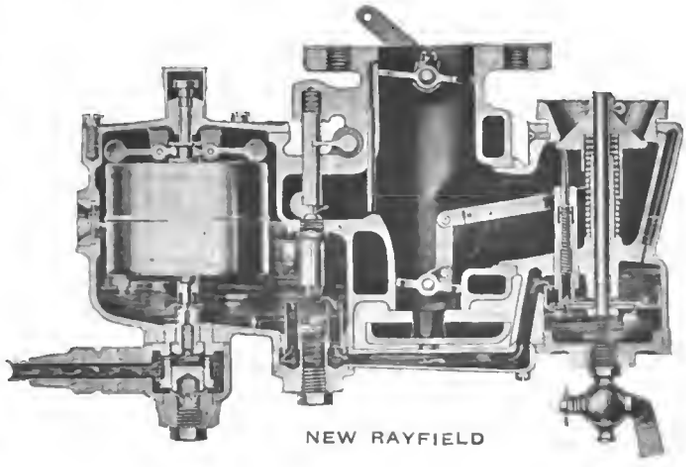


SCHEBLER

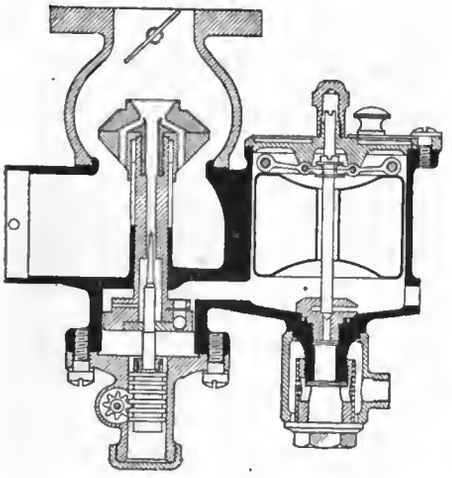
Wheeler & Schebler has a new model which is just about ready for announcement, although details cannot be furnished at this time. Aside from this, there are no new models, those which are carried over being R, L and P. These are what may be termed the overcompensated type in which the needle is lifted to a greater extent than normally would be required giving a wider fuel opening with the proper air compensation secured through the air valve. The needle is hooked to the air valve and when the latter lifts it lifts the needle. This applies directly to the model L and the model T is inverted type of model L and R, in which the needle is depressed to open. Proper atomizing of the fuel is provided by the velocity of the air carrying the fuel off the nozzle, by maintaining a large velocity and by heating the air.

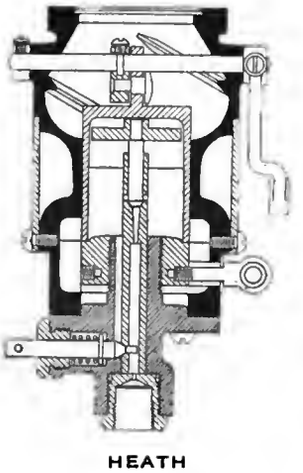
Rayfield Metering Pin Improved

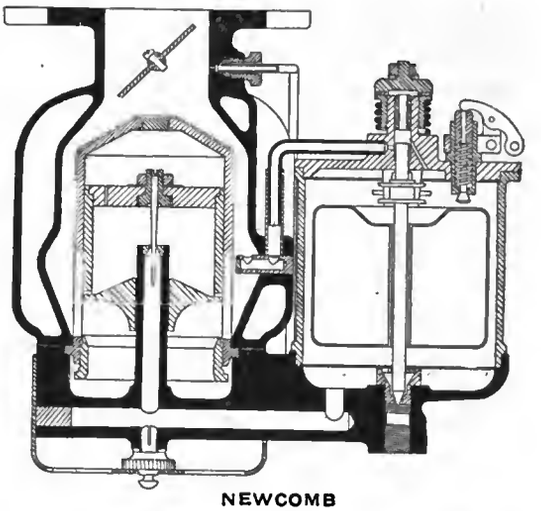
The chief improvement in Rayfield carbureters is the re-

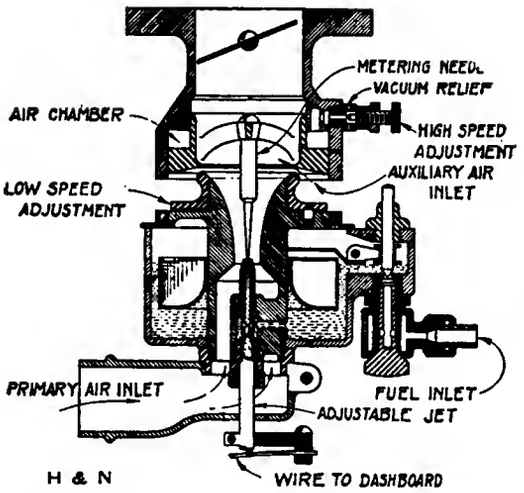


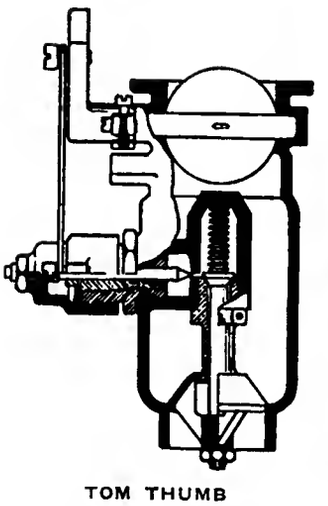
NEW RAYFIELD

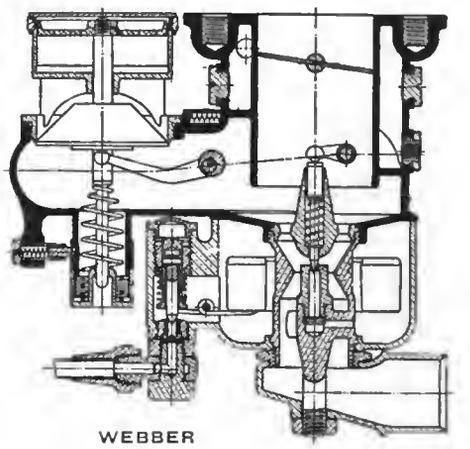












arrangement of the metering pin, which is operated by the upper air valve. Previously this pin was held against the air valve by a spring, and the valve had to overcome the reaction of the spring to operate it. Now the metering pin rides on the dash pot piston, which is on the lower end of the air valve stem, and moves upward and downward with the valve, but without requiring any greater effort by the valve.

Findeisen & Kropf, the manufacturers, are continuing the model G as the chief feature of its production program for 1917. This is not a new model, but the above detail refinements designed to give quicker acceleration and take care of the lower grades of fuel have been made. While the model G is the prominent one of the line, there is a model L the same in every respect except that it is not water-jacketed, which is the horizontal type of the model L.

Rayfield is classified as a metering pin type, but it goes further: It incorporates an auxiliary nozzle, which also has a metering pin which is depressed when the auxiliary air valve opens. Thus by having two distinct nozzles it establishes its right also to be classified as an expanding type of instrument. But Rayfield goes still further in that it combines a pumping action on the gasoline in the auxiliary nozzle whereby a very rich mixture is furnished for acceleration whenever the air valve is opened suddenly. This is accomplished by the piston on the lower end of the air valve stem, this piston working in a dashpot filled with gasoline. Gasoline enters the dashpot above the piston and is admitted to the space below the piston by the disk valve in the piston. When the air valve suddenly opens, forcing the piston downward, this disk valve is closed automatically, forcing or pumbping the gasoline upward through the fuel passage into the nozzle, where it is sprayed into the inrushing air. Only when the valve opens is this pumping function occurring and at other times the gasoline issues through this auxiliary nozzle according to the suction of the motor. Thus Rayfield is a compound of two metering pins in conjunction with the pumping function for acceleration. The dashpot also prevents air valve fluttering.

Stewart Line Unaltered

No new models and no changes are incorporated in the Stewart line. This is a metering type of carbureter in which the vacuum at the jet is controlled by the weight of the metering valve surrounding the upright metering pin. The only moving part is the metering valve which rises and falls with the changes in vacuum. The air chamber surrounds the metering valve, and there is a mixing chamber above. As the valve is drawn up, the gasoline passage is enlarged on account of the predetermined taper on the metering pin and the air passage is also increased propertionately, giving the correct mixture. A dashpot at the bottom of the valve checks flutter. In idling the valve rests on its seat practically closing the air and giving the necessary idling mixture. There is a passage through the valve which acts as an aspirating tube. When the valve is altogether closed the primary air passes through ducts in the valve itself, giving the proper amount for idling.

Newcomb Adds Pulverizing Plunger

Newcomb carbureters belong in the metering pin class and have had a pulverizing plunger added. The reason for this plunger is to more thoroughly mix the gas line and air and thus to assist in its vaporization. In addition to the main nozzle there is an auxiliary nozzle which leads to a point opposite the throttle to assist in starting.

Air entering the carbureter lifts the pulverizing plunger

which in turn lifts the needle out of the nozzle, permitting a certain quantity of fuel to escape into the chamber. This fuel passes through a number of small holes at the bottom edge of the plunger, these holes registering with an equal number of narrow air slots in the plunger tube. The air rushing through these slots mixes thoroughly with the fuel. The head of the plunger and the upper end of the plunger chamber form a dashpot.

Webber Metering Pin Models

Several models of metering pin types of Webber carbureters are made and they all operate on the same general principle. The nozzle is located in a venturi, as usual and the size of the orifice is altered by raising a needle, or pin, out of it through interconnection with the auxiliary air valve. The peculiarity of the Webber is that the mixture of air and gasoline, after leaving the nozzle, is caused to pass through a series of smaller venturi tubes arranged in a circle around the main venturi and above it. This causes the air and gasoline to be thoroughly mixed and vaporized.

H & N Control by Auxiliary Air

H & N carbureters belong in the metering pin class in which movement of the measuring device is controlled by the auxiliary air through an air dash pot. The primary air passes through a venturi, picking up its fuel from the nozzle in passing. For low speeds the fuel nozzle remains unchanged but at higher speeds the opening of the auxiliary air valve raises the metering pin and proportions the gasoline to the air which is flowing through the carbureter.

Heath Employs Vacuum

The Heath carbureter belongs in the metering pin class in which the quantity of fuel is proportioned to the air by the action of an air valve operated by the vacuum induced in the carbureter. In principle there is a valve floating on a tubular shaped column of air which rushes past the six openings of the fuel stud. The position of this valve depends upon the volume of air going through the carbureter and as the valve lifts it lifts the metering pin with it.

Tom Thumb

The Tom Thumb carbureter is a metering valve type in which the opening of the throttle increases the opening of the fuel port around the needle. This is accomplished by a connecting rod which turns the needle on a coarse thread to pull the needle away from the opening. When the engine is at rest a shut-off valve is pushed to a closed position by a spring. When the engine is running this valve is held open by the air valve. The fuel outlet is through six small holes.

Expanding Types Include Interesting Designs

ALTHOUGH the expanding types of carbureters are only 11 per cent of the total, they include some of the most interesting of all the modern designs. Among them are the Master and Carter. In these carbureters the jets come into action as they are needed starting with a primary for idling with jet after jet contributing its share of fuel as the throttle is opened further.

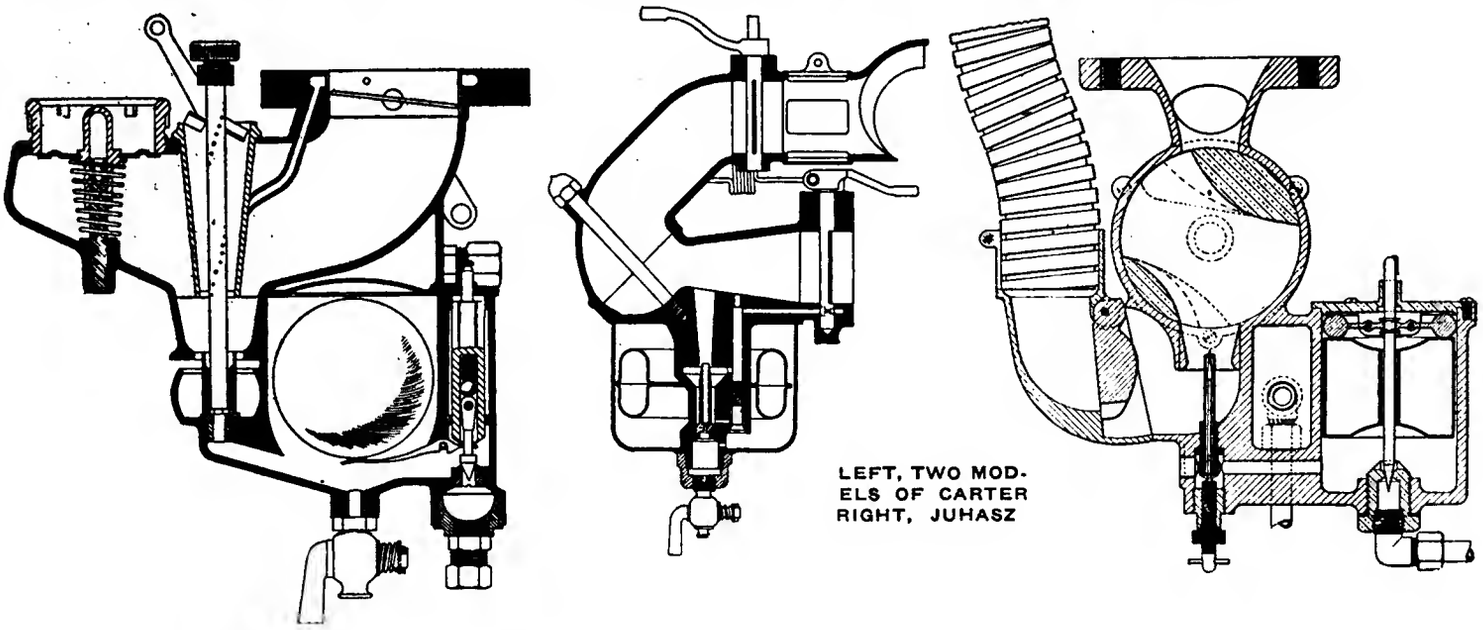
Master in Single Model

The Master carbureter is continued as a single model. Its principle of operation is the breaking up of the fuel by means of a series of jets which vary in number from 14 to 21, according to the size of the carbureter. These are uncovered by opening the throttle which is curved—a patented feature—in order to secure the correct progression of jets. The carbureter has an eccentric float chamber from which the gasoline is led to the jet piece from which the jets stand up.

The tops of these jets are closed until the throttle is opened far enough to pass them, which it does progressively. The air opening is at the bottom and the throttle opening is such that a modified venturi is formed. The throttle is carried in a cylindrical barrel with the jets placed below it and the passage from the barrel to the intake is arranged so that there is no interruption in the flow. For easy starting there is a dash-controlled shutter which closes off the air, throwing the suction on the jets, thus giving a rich mixture.

The only adjustment is for idling and once that is fixed it need never be touched. This is in the form of a screw and regulates the position of the throttle when at idling position. The dash control has high-speed, normal and rich starting positions.

The minor modifications on the Master are as follows: New design brackets for float weights, formerly integral lugs on cover. New steel stamping locked to float chamber with projections which fit into slots. This locks cover on float, whereas a circular wire was used. Float needle now monel

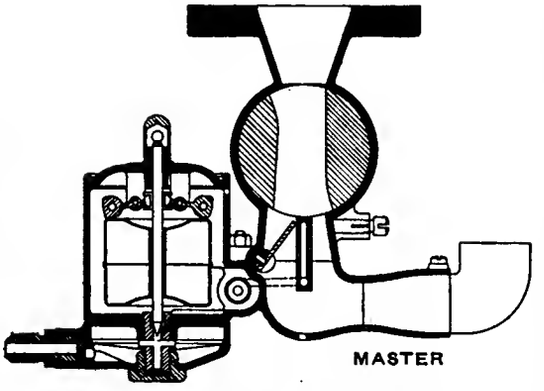


LEFT, TWO MODELS OF CARTER RIGHT, JUHASZ

metal instead of brass. All hot air now instead of semi-hot air.

New Carter Warms All Air

It has been mentioned that the three basic methods for taking care of the heavier fuel are by increased heat, better atomization, and higher velocities. The Carter carbureter uses all three, in its new model L which has just been put on the market. All the air that enters the new Carter instruments is warmed and comes through one opening. It is brought into contact with the various jets by means of venturi tubes permitting the passage of an exceptionally large volume of air to the engine with noteworthy increase in power and passing the jets at a very high rate of speed, thus greatly assisting in the atomizing process.



MASTER

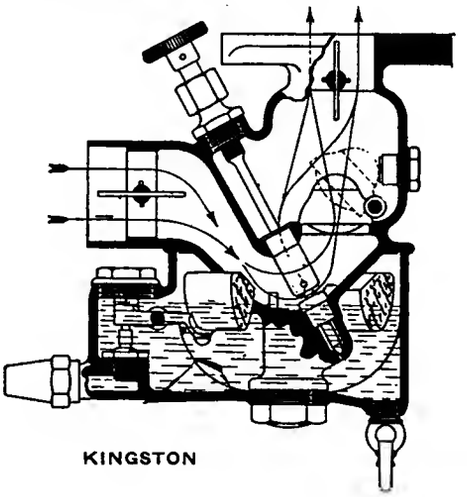
Five Models of Same Type

There are five models of Carter carbureters, all being the automatic expanding type. These are models C, hot water jacketed with low and intermediate adjustments which can be sealed after being set, designed for replacement business, on account of adjustability to varying conditions; Model CH, similar but designed for six, eight and twelve-cylinder cars; Model F, used for equipment purposes and also for special Ford outfit. It has no adjustment except a limited one for the float level. Model H is similar except that it has a steel float chamber. Model L has all the air received through one intake. It is designed especially for speed and power and easy starting. It is used only for equipment purposes except in the Ford outfit.

Juhasz Has Fixed Orifices

The Juhasz instrument belongs properly in the expanding carbureter class. It has a number of fixed orifices which are uncovered progressively as the rotary throttle is opened. Each orifice gives in effect an independent carbureter. At slow speed only one orifice is in operation and as the throttle is opened the second, and then the third, orifice comes into operation.

There are only three moving parts: the rotary throttle, the float and an auxiliary gravity operated air valve to control the admission of air to the middle carbureting chamber. With the throttle closed this valve is on its seat and permits just sufficient air to pass to give a rich mixture for idling. As the speed of the engine is increased the air valve lifts, increasing the flow of air in proportion to the increased flow of fuel and thus keeping the fuel supply in the proper proportion for various throttle conditions.



KINGSTON

Kingston in Miscellaneous Class

NONE of the four classifications given above suits the Kingston carbureter. Several Kingston carbureters are produced. For pleasure car use there is the Model L, which is applied as stock equipment on a large percentage of the Ford cars, and developed with slight changes for application to other cars. In addition, there are a number of models brought out for tractor, marine and stationary service under the general designation of Inclosed type, being designed for operation under conditions in which there is a great deal of dirt and dust in the air, the feature being that all the air is taken in at one intake, which may be protected from dirt. Of these, the Kingston Duplex is the most interesting, as it is arranged to operate both on kerosene and gasoline, having two float chambers, two nozzles, two mixing chambers, with a three-way valve to the manifold. Thus, it is in fact two distinct carbureters, one for gasoline and one for low-grade fuel, having only the connection to the manifold as a common part. This carbureter retains the old Kingston feature of ball valve.

Model L Heats All Air

The model L, which is the later design, has a concentric cork float around a jet placed at an angle from the vertical. The air, all of which is heated, is taken in through a single opening and swept downward through a curved passage whose shape gives it the proper velocity and direction to sweep across the end of the flat nozzle, thus picking up the fuel. The suction is regulated automatically by means of a flapper valve which assists in acceleration and whose action is explained below.

There is always a pool of gasoline at the base of the tube when the motor is not running. This is for the purpose of positive starting. When the motor starts this pool is quickly lowered to a lower portion of the tube, depending on the adjustment of the needle valve and continues to feed from this point until the motor is stopped.

When the motor is running slowly the air valve rests lightly on its seat, allowing no air to pass, consequently all air must pass through the low-speed tube, as the lower end of this tube is close to the spray nozzle and all the air at low speed has to pass this point, the atomized gasoline drawn from the nozzle becomes thoroughly mixed with the air in its upward course.

As the throttle is opened the air valve rises, permitting a small volume of mixture to pass by, due to the suction of the engine. At this point a change in operation occurs. The low-speed tube still continues to deliver a perfect mixture, but is being assisted by the air valve opening. The air must pass across the spray nozzle between it and the low-speed tube. As the motor speed is increased up to its maximum the air valve continues to rise higher, permitting more and more air, which passes across the spray nozzle with no increase in velocity and picking up the gasoline from it.

Industrial Miscellany

Factory

American Auto Trimming Co., Cleveland, has leased quarters in which it will establish a plant.

W. A. McManus and **F. A. Hagner**, of Newark, N. J., have formed the General Safety Signal Co., with a capital of $500,000 to manufacture safety signal devices for automobiles.

Crown Tire & Rubber Co., Omaha, Neb., is about to start the building of the first unit of a tire and rubber plant, for which 5 acres has been purchased in a manufacturing suburb of Omaha. The company will produce 300 tires and 250 tubes daily. It is planned to have the building up and machinery installed about Aug. 1 next. An output of fifty tires a day, both cord and fabric types, will be undertaken in a temporary location.

K. D. Carbureter Co., Cleveland, will erect a new three-story concrete factory, 100 by 250 ft.

Sayres & Scoville Co., Cincinnati, carriage builder, will enlarge its factory to devote its manufacture to automobiles and special motor trucks.

H. P. Miller, Fort Worth, Tex., plans to build a plant at Dallas for the manufacture of an automobile appliance.

Saunders Motor Power Co., East St. Louis, Ill., is preparing to equip a plant for the manufacture of a rotary motor operated with steam, gas or gasoline. J. H. Keys is president.

Midcontinent Tire Mfg. Co., Wichita, Kan., will build the first unit of its plant. This will cost $65,000 and will be two stories, 60 by 280 ft.

Pierce-Arrow Motor Car Corp., Buffalo, N. Y., will erect a sand blast and pickling building of steel construction.

Anger Engineering Co., Milwaukee, will build a plant at Twenty-sixth and State Streets.

Locomobile Co. of America will erect a one-story, 100 by 160-ft. addition.

B. P. Motor Car Co., Peoria, Ill., has been incorporated to manufacture motors for automobiles and other machines. Temporary quarters have been secured at 418 Main Street. A new building is planned on Hamilton Street, to be erected as soon as the old opera house structure is demolished. The officers of the company are as follows: President, E. T. Beatty; vice-president, R. U. Pfeiffer; secretary-treasurer, J. S. Pfeiffer.

DeLion Tire & Rubber Co., Trenton, N. J., is about to erect a three-story, 65 by 175-ft. addition.

Alpha Rubber Mfg. Co. will locate its plant in Genoa, Ill. The company is capitalized at $1,000,000 and will occupy the piano factory in the west end of the city. It will manufacture tires. Seventy-five men will be employed at the beginning. J. A. Berger is president and general manager.

Atwater Kent Mfg. Co., Philadelphia, manufacturer of ignition systems, is erecting a one-story factory building at 4937 Stenton Avenue.

Autocar Co., Ardmore, Pa., recently marked the close of one of the most successful years in its history by entertaining its salesmen and branch managers at the factory. Among those in attendance were W. T. Savoye, New York; J. E. Higgins, Providence; R. P. Page, Boston; M. S. Bulkleym, Los Angeles; K. B. Harwood, Chicago; A. H. Bishop, Baltimore, and A. E. Fisher, Newark.

J. B. D. Resilient Wheel Mfg. Co., Milwaukee, which was organized about 3 years ago to manufacture and market a solid-tire wheel for passenger cars and trucks, has changed its corporate style to the Motor Parts Machine Co. The plant at 675 Smith Street has been extended and enlarged to include the production of a varied line of car, truck and tractor parts for the trade.

The Automobile Calendar

ASSOCIATIONS

Jan. 6-13—New York, Mid-Winter Meeting of Society of Automobile Engineers, Engineering Society Bldg.
Jan. 9—New York City, National Automobile Chamber of Commerce, Annual Banquet at Waldorf-Astoria.
Jan. 9-11—New York City, Society of Automobile Engineers' Mid-Winter meeting, Thursday, Jan. 11, S. A. E. day. Annual Banquet, Hotel Biltmore, Special performance Ziegfeld's Midnight Follies.
Jan. 10—New York City, Motor and Accessory Manufacturers' Banquet, Waldorf-Astoria.
Feb. 1-2—Chicago, Ill., Annual Convention American Assn. of Garage Owners, Auditorium Hotel.

CONTESTS

1917

April—Los Angeles to Salt Lake City Road Race.
May 19—New York Metropolitan Race on Sheepshead Bay Speedway.
May 30—Indianapolis Speedway Race, Championship.
June 9—Chicago, Ill., Speedway Race, Championship.
June 23 — Cincinnati, Ohio, Speedway Race.
July 4—Omaha, Neb., Speedway Race, Championship.
July 14 — Des Moines, Iowa, Speedway Race, Championship.
July 4—Tacoma, Wash., Speedway Race, Championship.
Aug. 4—Kansas City Speedway Race.
Sept. 3—Cincinnati, Ohio, Speedway Race, Championship.
Sept. 15 — Providence, R. I., Speedway Race, Championship.
Sept. 29—New York, Speedway Race, Championship.
Oct. 6—Kansas City Speedway Race.
Oct. 13—Chicago Speedway Race.
Oct. 27—New York Speedway Race.

SHOWS

Dec. 9-16—Akron, Ohio, Show for Passenger Cars Only, Market Street Gardens, Akron Automobile Dealers' Show Assn.
Dec. 18-20—San Francisco, Cal., Automobile Salon De Luxe, Palace Hotel, I. R. Gates, Mgr.
Dec. 26-27—Olean, N. Y., Show, Armory Hall.
Dec. 30-Jan. 6—Cleveland Automobile Accessory Show, Dreamland Auditorium.
Dec. 30-Jan. 6—Cleveland, Ohio, Sixteenth Annual Show, Wigmore Coliseum, Cleveland Automobile Club.
Jan.—First Pan-American Aeronautic Exposition, New York City; Aero Club of America, American Society of Aeronautic Engineers, Pan-American Aeronautic Federations.
Jan. 2-10—New York, Automobile Salon, Hotel Astor, J. R. Eustis, Mgr.
Jan. 6-11—Milwaukee Auditorium, Milwaukee Automobile Dealers.
Jan. 6-13 — New York City, Show, Grand Central Palace, National Automobile Chamber of Commerce.
Jan. 12-20—Philadelphia, Show, Philadelphia Automobile Trade Assn.
Jan. 9-10 — Fort Dodge, Ia., State Convention, Iowa Retail Automobile Dealers' Assn.
Jan. 20-27—Detroit, Mich., 16th Annual Show, Detroit Automobile Dealers' Assn.
Jan. 22-27—Rochester, N. Y., Show, Exposition Park, Rochester Auto Trades Assn.
Jan. 22-27—Manchester, N. H., Academy.
Jan. 22-27—Buffalo, N. Y., Show, Broadway Auditorium, Buffalo Automobile Dealers' Assn.
Jsn. 23-27 — Baltimore, Md., Show, Fifth Regiment Armory.
Jan. 25-27—Asheville, N. C., Show, Asheville Automobile Trade Assn.
Jan. 27-Feb. 3—Columbus, Ohio, Show, Memorial Hall, Columbus Dealers' Assn.
Jan. 27-Feb. 3, 1917—Chicago, Ill., Show, Coliseum, National Automobile Chamber of Commerce.
Jan. 27-Feb. 5—York, Pa., Show, York Automobile Dealers' Assn.
Jan. 20-27—Montreal, Que., Automobile Trade Assn.
Jan. 28-Feb. 3—Wilmington, Del., Show, Hotel duPont.
Feb.—Newark, N. J., Show, First Regiment Armory.
Feb. 3-10—Minneapolis, Minn., Show, Minneapolis Automobile Trade Assn.
Feb. 5-9—Boston, 8th National Good Rosds Show, Mechanics' Bldg.
Feb. 5-10—Bangor, Me., Bangor Automobile Assn., Auditorium.
Feb. 10-18—San Francisco, Cal., Pacific Automobile Show, G. A. Wahlgreen, Mgr.
Feb. 12-17 — Louisville, Ky., Show, First Regiment Armory, Louisville Automobile Dealers' Assn.
Feb. 12-19—Indianapolis, Ind., Show, Steinhart Bldg., Indianapolis Automobile Trade Assn.
Feb. 19-24—Grand Rapids, Mich., Show, Automobile Business Assn. of Grand Rapids.
Feb. 14-17—Peoria, Ill., Coliseum, Automobile and Accessory Dealers' Assn.
Feb. 18-25 — St. Louis, Mo., Show, Automobile Manufacturers' and Dealers' Assn.
Feb. 19—Pittsfield, Mass., Show, Armory. J. J. Callahan, Mgr.
Feb. 19-24 — Duluth, Minn., Show, Duluth Auto Dealers' Assn., Armory.
Feb. 19-24—Bridgeport, Conn., Show, Armory, Coast Artillery Corps.
Feb. 19-24—St. Louis, Overland Bldg., St. Louis Auto. Dealers' Assn.
Feb. 19-24—Syracuse, N. Y., Show, State Armory, Syracuse Dealers' Assn.
Feb. 24-March 3 — Brooklyn, Show, 23rd Regiment Armory.
Feb. 26-March 3—Omaha, Neb., Show; Auditorium, Omaha Automobile Show Assn.
March 1, 2, 3—Urbana, Ill., Show, Automobile Trade Assn. of Champaign Co. Armory of the University of Ill.
March 3-10 — Boston, Mass., Show, Mechanics' Bldg., Boston Automobile Dealers' Assn.
March 6-10—Ft. Dodge, Iowa, Northern Iowa Show, New Terminal Warehouse, G. W. Tremain, Secretary.
March 14-17—Davenport, Iowa, Show, Coliseum Bldg., Tri-City Automobile Trade.
March 18-23—Cedar Rapids, Ia., Cedar Rapids Automobile Trades Assn.
April—Calumet, Mich., Show, Coliseum, Frank Ketchell, Mgr.

Elgin Motor Car Co., Chicago, has completed a ¾-mile test track, over which every car is tested before shipment. The Elgin factory is also located near a steep hill, which provides opportunity to test the hill-climbing qualities of every car.

Sheller Wood Rim Mfg. Co., Portland, Ind., manufacturing single-piece wooden rim automobile steering wheels, is making plans for a factory.

Davis Mfg. Co., Milwaukee, a manufacturer of gasoline engines for trucks, tractors, railway coaches and similar purposes, is reported to be preparing to make important works extensions, made necessary by the extraordinary demand for its products. The new building, it is said, will consist of a shop, 124 by 225 ft., and a pattern shop, 30 by 90 ft.

Elwell-Parker Electric Co., Cleveland, maker of storage battery industrial trucks and tractors, will enlarge its plant by the erection of a four-story building, 60 by 120 ft. This will be a duplicate of an extension built some time ago. A third unit of the same size is contemplated early next year.

Personals

J. F. Douse has been appointed sales manager and advertising manager of the George W. Miller Co., Seattle. Previous to this change Mr. Douse was manager of the Seattle branch of the Fisk Rubber Co. Mr. W. P. Williams will remain as general manager of the George W. Miller Co.

Herbert Dovey has been appointed manager of the Sturgis & Storie Co. of Walla Walla, Wash., agent in Walla Walla for the Buick, G. M. C. trucks and Bull tractors.

H. C. Plow has purchased the Automobile Owners' Accessory Co., Ltd., of Montreal, Can. Mr. Plow, who is known to the industry as "Hy" Plow, was at one time treasurer of the Hartford Rubber Co.

J. E. Morehouse is manager of the Detroit branch of the Scripps-Booth Corp. The branch was recently opened.

George Grow, Boston, used-car dealer, has purchased from the Willys-Overland Co. the four-story building on West Newton Street that had been used by the Connell & McKone Co., eastern Massachusetts Overland dealer, as a service station for the past 5 years.

R. C. Wilson has been appointed general manager of the Columbus Cadillac Co., Columbus, Ohio, succeeding E. C. Moliter. Mr. Wilson has been a director and sales manager of the Standard Motor Car Co. there.

V. A. Seiders has been appointed Southern sales agent for the Bell Motor Car Company, York, Pa., and will cover the States of Virginia, North Carolina, South Carolina, Georgia, Alabama, Florida and Tennessee.

A. B. MacGowan, formerly in the sales promotion department of the Chase Motor Truck Co., Syracuse, N. Y., is now city sales manager for that company at its Philadelphia branch.

D. F. Shanahan of Covington, Va., has joined the sales force of the Chase Company as special traveling representative.

F. L. Terry, who for the past 4 years has had service on S. G. V. and Fiat cars, has taken in a partner, R. E. Hardy, and opened an accessory store at 1441 Bush Street, San Francisco. The firm is known as Terry & Hardy, accessory dealers and Firestone distributors.

H. E. McEldowney of Seattle, Wash., has been appointed agent for the Hendrick's 1-ton truck attachment in Tacoma, Wash., and surrounding territory.

S. W. Dorman has become purchasing agent of the automobile accessory department of the Biddle Purchasing Co., New York.

Jack De Mont, Atlanta, Ga., for more than a year manager of the Willard Storage Battery Co. branch, has been transferred to New York and Al. C. Hyser of Cleveland, Ohio, succeeds him as Atlanta manager.

A. H. Abel, Birmingham, Ala., has become sole owner of the Abel-McCay Wagon Co. and has changed the name to A. H. Abel Wagon Co. In addition to automobile repairing the company will sell Redden trucks.

N. B. Ford, who for 10 years traveled for the Corbin Screw Corp. from its Chicago office, having his headquarters in Kansas City, and who left some 2 years ago to become connected with the Ford Chain Block & Mfg. Co., Philadelphia, has re-entered the employ of the Corbin Screw Corp. as salesman, with headquarters in New Britain and covering the territory formerly traveled by A. H. Harrop.

C. B. Lindeman, formerly Western advertising representative of the Firestone Tire & Rubber Co., has been appointed head of the creative division of the company with offices in Akron.

W. J. Denning has recently been appointed manager of the cataloging and advertising departments of the Auto Parts Co., Chicago.

J. L. Hamilton, secretary of the Bay State A. A., has formed a partnership with Stanley Hall, one of the directors, and it is named the H. & H. Motor Specialties Co., to handle accessories.

W. E. Hennigan, for many years with the Winton New England branch, and Herbert Ramsey, a former Hupmobile man, have joined the sales force of the Harry Fosdick Co., handling the Pathfinder at Boston, Mass.

J. J. Devaux has resigned as Oregon distributor in Seattle for the Chevrolet car in order to take the agency for the Regal car in Lower California.

F. H. Downes has been appointed head of the Smith Form-A-Truck department of Ballou & Wright of Portland, Ore.

W. E. Duersten, formerly production and efficiency expert of the Western Electric Co., and later connected with the Hudson factory, has been named factory superintendent for the Macon Motor Co., Macon, Mo.

O. R. Randall, for 7 years sales manager of the Middle Western and Southwestern territory of the J. I. Case T. M. Co., Racine, Wis., has resigned, effective Jan. 1, to engage in business at Atlanta, Ga., as State distributer for Georgia of a line of pleasure cars, trucks and tractors, the names of which are not yet divulged. Mr. Randall joined the Case Company in 1901, first as agent in Atlanta. In 1909 he was called to the home offices to accept one of the most important posts in the sales organization. His son, E. A. Randall, now associated with the Western Advertising agency of Racine, will become associated in the new venture at Atlanta.

E. A. Jacob succeeds J. W. Wildman as manager of the Des Moines, Iowa, branch for the Portage Rubber Co. Mr. Wildman leaves to take charge of the Chicago Portage branch.

J. B. Brugler has been appointed manager of the new Indianapolis branch of the Racine Horse-Shoe Tire Co., Racine, Wis., which has just been opened at 249 North Pennsylvania Street.

H. P. Nelson has become treasurer and sales manager of Robert Lurie & Co., New York, handling the Metz.

Dealers

Kelly-Springfield Tire Co. has opened a factory branch at 1225 Harmon Place, Minneapolis, succeeding the Boger-Stiess Rubber Co., its agent for 2 years. G. M. Martin, manager for the Firestone Tire & Rubber Co. branch at 1635 Hennepin Avenue, is appointed manager. The territory is Minnesota, the Dakotas, western Wisconsin and western Canada. A. C. Searles is new manager for the Firestone company.

F. B. Stearns Co. of New York announces that the wholesale end of its business is now in charge of the factory branch. The wholesale business was formerly handled by Charles E. Riess & Co., metropolitan distributor of the Hupmobile.

Metz cars will be distributed in Chicago by James Haddie at 729 Lyman Avenue, Oak Park.

Troy motor truck trailers will be handled by the Barden Electric & Machinery Co., Houston, Tex., and by the O'Rourke-Muller Motor Co., New Orleans.

Chalmers Motor Co., Detroit, has issued to all its dealers plans for an effective service inspection. During 1917 each Chalmers dealer or distributor will maintain a Standard Chalmers service car which will be distinguished by its color scheme of red and black. This car will have a red body, black hood and running gear.

Willard Storage Battery Co., Cleveland, has added during the past month about sixty new service stations, making the total up to 831.

Benton County Hardware Co., Rogers, Ark., a wholesale hardware concern, which operates a string of retail stores and travels a number of salesmen, has added automobile accessories to its jobbing line. The company is contracting accessories on a jobbing basis and compiling an extensive catalog.

Packard Motor Car Co., Philadelphia, will build an eight-story steel and concrete service plant, 70 by 185 ft., at Broad and Wood Streets.

Padgitt Bros. Co., Dallas, Tex., has closed contracts for the Texas agency for the Kelly-Springfield and Commerce trucks and for the Babcock and Parry commercial bodies and for the Racine tires.

Cole Automobile Co., Peoria, Ill., has removed from 1812 Main Street to a new location at 103 Ellis Street, and will operate a sales agency, garage and service station. Eugene Hayden is now distributor for the Cole in Peoria and vicinity.

Denver Auto Goods Co., Denver, has taken the Colorado distributing agency for Pennsylvania tires.

R. E. Williams Motor Car Co., Denver, a new concern, has secured the Abbott-Detroit distributing agency for Colorado and southern Wyoming.

ANOTHER WINTER BUSINESS LEADER

All Stewart Products are necessities for winter driving. That is why they are such big sellers every day—week in, week out—in all seasons.

Of these, the Stewart Vacuum System is very important. In winter, a positive, unfailing gasoline feed is necessary to insure quick starting, and smooth running of the motor.

The Stewart Vacuum System maintains a constant supply of gasoline above the carburetor. This insures a perfect gasoline feed; besides, keeps the gasoline warm, which makes starting easy.

Most new cars are equipped with the Stewart Vacuum System. Thousands of old cars are not. The owners of these old cars would quickly install a Vacuum System if some enterprising dealer would point out its advantages, particularly for winter driving.

Here is a big opportunity for dealers to add to their winter business. Drive away the dull-winter-business period by going after this business which is plainly in view.

There is also a big business awaiting dealers on the Stewart Speedometer, Warning Signal, Tire Pump, and V-Ray Spark Plug.

"It will pay you to see that every car is Stewart-equipped"

The AUTOMOBILE

VOL. XXXV NEW YORK—THURSDAY, DECEMBER 21, 1916—CHICAGO NO. 25

"Automotive" Saves Industry

Aviation Industry Threatened by Patents Looks to Automobile Example for Salvation

NEW YORK, Dec. 20—The budding industry of aeroplane manufacture has been threatened by a claim from the holders of the Wright patent for the double-acting aileron, much as the automobile industry was threatened years ago by the Selden patent. The Wright patent is not upheld any more strongly than the Selden patent was at first, but it seems that the situation may serve to weld the aviation industry, just as the Selden patent helped to weld automobilism. The patent refers to warping the ends of the wings for stabilizing purposes.

The Wright patent has 6 years to run, and the holders, the Martin-Wright Co., is asking all users of the patent to pay 5 per cent of the *gross* price of their product as royalty. With firms that have taken government contracts this represents all the difference between profit and loss. The near $30,000,000 which the United States Government is going to spend on aeroplanes is enough to establish a free industry that may be of inestimable value to the nation in years to come. The imposition of so great a tax upon this sum at the outset may easily be the equivalent of throttling an infant industry of vast national importance before it has drawn its first full breath of life.

Following the Wright patent announcement the Curtiss company, which owns uncontested master patents covering the hydro-aeroplane, has stated that if one tax is placed upon the industry it will also claim its rights. It is understood that the attitude of Curtiss has been taken partly with a desire to bring matters to a head so that some rational settlement can be reached. The Curtiss patents are of very recent date and, like the Wright double-acting aileron patent, are susceptible to much litigation.

Referred to Government

The matter has been referred by the industry to the Aero Club of America, which has turned it over to the Council of National Defense, since it affects the nation much more than any individuals. The United States Government has decided that the safety of the country is wrapped up with the efficiency of the air services of the army and navy to the extent that it is going to spend huge sums to establish the young industry. The club considers that anything that will restrict the growth of aeroplane manufacture at the present time is inimical to the safety of the nation. For this reason it is putting the matter before a body than can call upon the National Automobile Chamber of Commerce and use its organization for dealing with patent questions; that can deal directly with the contestants as representative of the government, and that is above any possible suspicion of personal favor. The Selden patent took years to settle; the Aero Club hopes that the N. A. C. C. and the Council of National Defense may be able to settle the present problem in as many days as the Selden patent took years.

The automobile industry was not in its early days regarded of national importance. It had no $30,000,000 grant from the government, no huge organizations to look to for support in difficulties. The aviation industry, already helped into existence by the automobile, is going to lean upon its parent in this, the first great problem of its young life.

No doubt what will happen is that the patent holders and those who want to use the patents will get together and settle the question. They will have the experience of the N. A. C. C. to call upon, the prestige of the government to dignify the consultation. Thus an early and satisfactory settlement is to be expected.

Highway Tractor Co. Incorporated

Organization of $2,000,000 Concern Completed—McCutchen Is President

INDIANAPOLIS, Dec. 19—The Highway Tractor Co., capitalized at $2,000,000 and headed by Carl G. Fisher, James A. Allison and Henry F. Campbell, of this city, was incorporated here last week to manufacture tractors with 10-ton drawing power for highway and military use. Work is to be started immediately on a site of 25 acres near the Indianapolis Motor Speedway on the first unit of a plant to cost $200,000. The company expects to have the plant in operation by May 1, employing 300 men, and working on material that has been purchased for the manufacture of 5000 tractors next year.

McCutchen Heads Co.

Charles G. McCutchen, who recently resigned the presidency of the Ross Automobile Co., of Detroit, will be president of the Highway company, and Mr. Fisher will be secretary-treasurer. Plans call for the construction of a concrete and steel plant 200 by 400 ft. The tractor will feature many of the inventions of B. R. Parrott of Jackson, Mich. A. E. Schaaf of Poughkeepsie, N. Y., recently with the Fiat Automobile Co., and formerly manager of the Pope-Toledo Automobile Co. of Toledo, Ohio, will be factory manager. Other stockholders in the company are Louis Goodhart of St. Louis, Dr. M. N. Stewart and Forrest C. Badgley, both of Jackson, Mich.

The company announces it probably will build a tractor with a 5-ton drawing power in the near future, and later may enter the farm tractor field. The price of the 10-ton drawing power machine will be approximately $1,250.

400 at Manufacturers' Banquet

Speeches by Prominent Men in Automobile Industry Enthusiastically Received

DETROIT, Dec. 15—The Manufacturers' Banquet, given by the Society of Automobile Engineers, last night witnessed the attendance of more than 400 guests and members, and a most enthusiastic spirit blended with serious discussion and wholesome and enjoyable entertainment.

Brilliant, substantial and amusing speeches, an orchestra, several singers, and a moving picture combined with the dinner served to make the evening one of solid pleasure. Among the speakers were Coker F. Clarkson, general manager of the S. A. E.; Job Hedges, of New York, Captain L. E. Goodier, Jr., of the aviation service; H. M. Leland, president of the Cadillac Motor Car Co., Russell Huff, president of the Society of Automobile Engineers, and Howard Coffin, director of the Hudson Motor Co. K. W. Zimmerschied, engineer for the General Motors Co., acted as toastmaster.

Growth of the S. A. E.

D. McCall White, chairman of the Detroit section, introduced Mr. Zimmerschied, who made an entertaining speech and introduced Mr. Huff, who discussed the future outlook for automobile engineers. Mr. Clarkson told of the growth of the Society and of the probable amalgamation of other societies working in similar fields with the Society of Automobile Engineers. Mr. Leland commenced his address with a number of humorous stories and later developed the serious and important subject of industrial unrest and its possible consequences. Mr. Hedges in a speech filled with amusing critical shafts aimed at different guests and members present, brought rounds of laughter, and completed his discussion with a thoughtful talk on the need of patriotism, the deplorable lack of sentiment that exists in the country to-day and its importance above more material things. Captain Goodier and Howard Coffin discussed at length the subject of aviation and the general need for industrial preparedness. Captain Goodier told of the vast increase In appropriations for army aviation and of the gap it caused in the number of men and machines required, and wound up his address with an appeal to the engineers and manufacturers to join in the aviation reserve with their mental and physical strength and manufacturing resources. Mr. Coffin told of the aviation work he had witnessed at General Pershing's camp. He stated that aviators made many daily trips over mountains, requiring 2 days' travel in an automobile, and carried the mail from the camp to its destination in less than 70 min. He told of a route proposed over the Lincoln Highway which will be dotted with landing places within the next 8 months and will be known as the Lincoln Aereo Highway, and predicted that the use of aircraft of all sorts will be a common matter in the very near future.

In the course of his discussion, Mr. Coffin pointed out the vast quantity of aircraft now in use in the war and compared it with the few machines in the army of this country, showing how slow our manufacturers of aircraft and other war supplies are in the making of them, and urged the makers of automobiles to throw their resources into the work in accordance with the plea of Captain Goodier.

The evening wound up with the display of the moving picture The Eagles Wings, which dwelt on industrial preparedness, and was discussied, while shown, by Mr. Coffin.

Among others who attended were W. C. Anderson of the Anderson Electric Co., Hugh Chalmers of the Chalmers Motor Car Co., R. D. Chapin, of the Hudson Motor Car Co., George Dunham, John F. Dodge, of Dodge Brothers, Garvin Denby, of the Denby Motor Truck Co., H. W. Ford, of the Saxon Motor Car Corp., Professor Walter T. Fishleigh of the University of Michigan, Alfred Giauque of the Puegeot Co., of Paris, Christian Girl, president of the Perfection Spring Co., H. M. Jewett, president of the Paige-Detroit Motor Car Co., Paul E. Kelecom, of the Peugeot Co., of Paris, F. E. Moscovitz of Nordyke & Marmon, Percy Owen, of the Liberty Motor Car Co., W. C. Rands of the Motor Products Co., and Artemus Ward, Jr., of the King Motor Car Co.

—

Meyer Resigns from Maxwell Directorate

NEW YORK, Dec. 19—Eugene Meyer, Jr., has resigned from the directorate and executive committee of the Maxwell Motor Co., Detroit. A meeting of the directors will be held soon to elect a successor. Mr. Meyer, who is the head of the Stock Exchange house of Eugene Meyer, Jr., & Co., has been associated with the Maxwell company since its organization.

—

Heater Heads Bucyrus Rubber

BUCYRUS, OHIO, Dec. 14—Philip Heater was elected president of the Bucyrus Rubber Co., this city, to succeed R. O. Perrott, who resigned 6 months ago. The balance of the officers were re-elected at the annual meeting, as follows: Vice-president, George Donenwirth; secretary, C. P. Mador; and treasurer, W. A. Blicke.

$1,000,000 Additions for Buick

To Produce 750 Cars a Day—Gross Sales for 4 Months Total $57,516,876

DETROIT, Dec. 16—The Buick Motor Co., Flint, Mich., will be enlarged by an expenditure of $1,000,000 to enable it to produce 750 cars per day. The company is producing 550 cars per day at present.

Gross sales of the General Motors Corp. for the four months ending Nov. 30 were $57,516,876.12 and net earnings for that period were $9,195,733.64 applicable to the common stock. November business was the greatest in the history of the company.

—

$1,010,000 Back Royalty for Perlman

NEW YORK, Dec. 18—The Perlman Rim Corp. has received a check for $1,010,000, covering back royalties from the Standard Welding Co., Cleveland, as determined by the special master appointed by the court. This brings to an end the famous legal battle between L. H. Perlman, inventor of the demountable rim, and the Standard Welding Co., the decision in favor of Mr. Perlman having been handed down in August, 1915, in the district court and confirmed by the circuit court of appeals in February, 1916. The Standard Welding Co. is now a unit of the Standard Parts Co., having merged with the Perfection Spring Co. The Standard Parts Co. name appears on the check.

—

Ford Loses First Court Tilt

DETROIT, Dec. 19—Henry Ford and the Ford Motor Co. were losers in their effort, yesterday, to obtain a reopening of the preliminary decision rendered in the injunction suit brought by the Dodge brothers to stop the plans for erection of a huge smelter plant at River Rouge for the transforming of crude ore into finished castings for Ford cars by a single heating process.

Attorneys for Ford stated that the injunction against the smelter would cost the company $6,000,000 a year, and Henry Ford offered to indemnify and pay the plaintiffs any damages that might later be awarded them as stockholders in the Ford Motor Co., by reason of the construction of the blast furnace, foundry, etc., if such works would be held illegal or unlawful, and further promised to pay all costs individually, that might accrue to the company if the later decision is against the erection of the smelter. The court refused to heed either promise and the injunction remains until the final hearing.

Standard Parts Co. to Expand

Perfection Spring Co. Sale Ratified and New Co. Will Double Factory and Force

CLEVELAND, Dec. 20—The Standard Parts Co., merger of the Perfection Spring Co. and the Standard Welding Co., will double its factory facilities and also the force of employees during the next 8 months. The company now occupies 800,000 sq. ft. and employs 4500 workers.

The sale of the Perfection Spring Co. to the Standard Parts Co. has been ratified by 95 per cent of the stockholders and the remaining 4 per cent are expected to follow suit. The board of directors announced in THE AUTOMOBILE last week will be augmented to fifteen when complete, the new members being presidents of automobile companies now negotiating to join the Standard Parts Co.

Of the $5,000,000 preferred stock issued, $4,000,000 was taken up in this city in 24 hr., the remaining $1,000,000 being held to exchange for old Perfection stock.

Net earnings of the Standard Parts Co. for the past 3 months are $450,000, or at the rate of $18 yearly per share of common stock.

There will be three departments. The spring department will continue the manufacture of Perfection springs, business in which is now running close to $3,500,000 yearly, nine contracts having been closed in the last 3 months for over $1,000,000; the rim and tube department will make demountable rims under the Perlman patents only and all types of unpatented rims and also truck bands. Business in this department is running at $600,000 a month, with future contracts on the books for over $5,000,000 worth of rims and $3,500,000 in tubes. The heater department business is increasing very rapidly, the company selling 2000 in December, 1916, as compared with 100 in December of last year. Several car makers with 100,000-car outputs yearly are negotiating for the heaters as standard equipment.

Under the new merger total net assets of the company must be 200 per cent of the preferred issue and the net quick assets must be 100 per cent thereof. No new preferred stock can be issued unless net earnings for the previous 2 years are three times the preferred dividend required for each of these years.

Taylor Is S K F Vice-President

HARTFORD, CONN., Dec. 19—S. B. Taylor, sales manager of the S K F Ball Bearing Co. of this city, has been appointed vice-president of the company, succeeding F. B. Kirkbride, who remains on the board. Mr. Taylor will remain in charge of sales.

G. A. Ungar, former representative of the company in Cleveland, Detroit and Pittsburgh, has been appointed technical manager and chief engineer, succeeding Uno Forsberg, who returns to Sweden after completing his work of creating the manufacturing organization of the S K F Ball Bearing Co. in this country.

Reo Stockholders Re-elect Officers

DETROIT, Dec. 19—Stockholders of the Reo Motor Car Co., of Lansing, Mich., met to-day and re-elected the officers and board of directors.

Covert Retires from Gear Co.

DETROIT, Dec. 19—B. W. Covert, president of the Covert Gear Co., Buffalo, N. Y., will retire from the company on Jan. 1, having disposed of his common stock. Control will pass to P. A. Clum of Rochester, N. Y., and F. E. Mosher of Buffalo.

Metz Announces 1-Tonner at $695

WALTHAM, MASS., Dec. 15—In order to meet the demand for lower-cost transportation by business men, the Metz Co. announces a high-duty 1-ton truck to sell for $695. The chassis frame is of 5 in. heavy channel steel, capable of more than its rated capacity load. The wheelbase has been lengthened to 130 in.

The final drive is by internal gear, direct on each wheel. The front wheels carry 32 by 3½ pneumatic tires, while the rears are equipped with 34 by 3½ solid rubber tires. It is built to speed up to 20 m.p.h. and weighs complete 2500 lbs.

The ½-ton Metz delivery car that stores throughout the country have found so valuable, will still be continued. This is a ½-ton truck, and sells for $500 to $600.

King Increases Prices Again

DETROIT, Dec. 19—The King Motor Car Co. has again increased its prices above those stated Nov. 15, when the last increase was made. The seven-passenger and four-passenger touring cars and the three-passenger roadster have been increased from $1,400 to $1,585, a raise of $185. The seven-passenger sedan has been increased to $2,150.

Stanley Steamer Prices Advanced

NEWTON, MASS., Dec. 18—The Stanley Motor Carriage Co. advanced its prices on Dec. 4, the five-passenger touring car going up from $1,975 to $2,200, the seven-passenger touring car from $2,075 to $2,300 and the three-passenger roadster from $1,950 to $2,200.

Eight Car Makers Increase Prices

Buick, Maxwell, Franklin, Standard, Paige and Auburn Included in List

DETROIT, Dec. 14—The Buick Motor Co., this city, will increase the prices of all its models on Jan. 15. Prices will be as follows: D-4-34, from $650 to $660; D-4-35, from $665 to $675; D-6-44, from $985 to $1,040; D-6-45, from $1,020 to $1,070; D-6-46, from $1,425 to $1,440; and D-6-47 from $1,800 to $1,835.

Maxwell Raises Car Prices

DETROIT, Dec. 19—The Maxwell Motor Co. has increased the prices of its touring and roadster models to take effect Jan. 1. The new price of the touring car is $635 as against $595 which was the old price. The new price of the roadster is $620 as against $580.

Franklin Price $100 Higher

SYRACUSE, N. Y., Dec. 18—The Franklin Automobile Co., this city, will advance its prices on all models $100 on March 1, 1917.

Standard Eight Prices $100 Higher

PITTSBURGH, PA., Dec. 18—The Standard Steel Car Co., this city, has raised the price of the Standard Eight $100, on its open models, effective Jan. 1. Seven-passenger touring car now sells at $1,900 and the four-passenger roadster at $1,850.

Paige Raises Open Car Prices

DETROIT, Dec. 19—The Paige-Detroit Motor Car Co. has advanced the prices on all its models. The new prices are Model 51 Stratford, seven-passenger touring, $1,495. Model 51 Brooklands, convertible roadster, $1,695. Model 39, Linwood, five-passenger touring, $1,175. Model 39, Dartmore roadster, $1,175. Prices of all closed cars remain unchanged.

Auburn Six Is $60 Higher

AUBURN, IND., Dec. 18—The Auburn Automobile Co. has increased its five-passenger light six $60, to take effect Jan. 1, 1917.

Allen to Drop $795 Car

FOSTORIA, OHIO, Dec. 20—The Allen Motor Co. will discontinue the manufacture of its $795 touring car and roadster after Jan. 10, 1917, and, in open models, will confine the 1917 production to the special finished Allen Classic touring cars and roadsters listing at $850.

Enlarge Standards Committee

Inclusion of New Branches of Automotive Engineering Means Great Expansion

DETROIT, Dec. 14—To provide for the broader activities of the standards committee work of the Society of Automobile Engineers it was voted to-day by the council of the society to reorganize the standards committee and enlarge it, so as to practically have a separate department for such work as aviation, agricultural tractors, marine engineering, and automobile engineering. With this object in view a committee of nine was appointed. The contemplated plan is to so organize the committee that much of the load of work will be taken off the shoulders of the chairman. An organization on similar lines to that of a government is possible, in which the chairman will be assisted by a cabinet or executive council of perhaps five or six. Each representative on the council will represent a department of the committee's activities such as aviation, tractor work, or marine or automobile engineering. Each member of the executive committee will in this way share the responsibility of the work with the chairman and be perhaps directly responsible for the standards work in the particular department he represents.

The committee reorganization consists of Coker Clarkson, general manager of the S. A. E.; A. L. Clayden, present chairman of the standards committee; John G. Utz, Perfection Spring Co.; K. W. Zimmerschied, metallurgist of the General Motors Co., and chairman of the standards committee in 1915; George H. Dunham, nominee for president of S. A. E. for 1917; Henry Souther, first chairman of the standards committee and now with the federal government in charge of aviation work; A. L. Horning, Waukesha Motors Co., as a representative of the agricultural tractor interest; Chas. E. Manly of the Curtiss company, representing aviation interests, and R. C. Coombs of the Prest-O-Lite Co., who has had a wide experience in marine engineering. The committee is expected to report at the January meeting of the society.

Additional Divisions?

In connection with standards committee work for next year it is generally understood that Mr. Utz will accept the position of chairman of the standards committee to succeed Mr. Clayden, engineering editor of THE AUTOMOBILE, who has held the position for the present year. Mr. Utz has for years handled divisions of the committee and is particularly well qualified to take up the work. His duties in this respect will be ably assisted.

The question of creating additional divisions of the standards committee was considered, particularly such divisions as relate to marine engineering and lubricating oils. The matter was referred to the special reorganizing committee. Other work to be assigned to the standards committee included: Test of wire wheel rims, thickness of pneumatic tire rims, and pneumatic tires for motor trucks.

It was decided that the consideration of aviation matters during the week of the New York aviation show should be handled by the Metropolitan section, in which connection it is probable that an afternoon will be given to the consideration of aviation standardization work and that a dinner in the evening will be followed by a meeting at which papers on aviation will be presented.

In addition to general routine work of the society, the council admitted sixty-six applicants into the various grades of society membership.

—

Hilborn Co. Takes Over Answer Plug Distribution

NEW YORK, Dec. 20—The Hilborn Co., Inc., has been formed here to handle the entire output of the Hill Insulating & Mfg. Co., which produces the Answer spark plug. The Hilborn company will handle a number of accounts of which the Answer plug is the first. The Hilborn company will control the entire distribution of the Answer plug, the Hill Insulating & Mfg. Co. hereafter confining its efforts exclusively to manufacturing. The Answer plug is mica insulated and the makers have placed themselves in a unique position by guaranteeing its operation for a definite mileage. The plug is guaranteed to operate perfectly for a minimum of 10,000 miles, and if it does not it will be replaced. Headquarters of the Hilborn company are at 535 Canal Street.

—

McLeod Concentrates on Fabricord Co.

ST. LOUIS, Dec. 18—N. W. McLeod, president of the Fabricord Tire Co., has severed his connection with the German Savings Bank of this city, of which he was president, to devote his entire time to the tire company.

—

Boydston Dauch Sales Manager

SANDUSKY, OHIO, Dec. 15—L. H. Boydston has become sales manager of the Dauch Mfg. Co., this city, maker of tractors. He was formerly sales manager for the company in Los Angeles. This company is now putting out a new tractor, known as the 10-20 model.

Indiana S. A. E. Talks Carburetion

Prof. Berry Emphasizes Correct Proportions—F. C. Mock Discusses Methods

INDIANAPOLIS, IND., Dec. 15—Two papers on carburetion were read and discussed to-night before the Indianapolis Section of the Society of Automobile Engineers. One was by Professor Berry of Purdue University and the other by F. C. Mock, chief engineer of the Stromberg Motor Devices Co. The conclusion reached by Professor Berry was that the correctness of the proportions of air and fuel in the gas is very important. Mr. Mock gave his attention mainly to the means for obtaining the perfect mixture called for by Professor Berry and described at considerable length some experiments made with glass carbureters and manifolds. He analyzed the widely varying conditions which a carbureter has to meet, showing how difficult a thing it is to design an automatic carbureter.

The discussion, which was thorough, had as its main topics the influence of the size of manifold and of heating the charge. In this prominent speakers were J. W. Esterline of the Esterline Co.; V. R. Heftler, Zenith Carbureter Co.; Frederick Purdy, of Findeisen & Kropf Mfg. Co., and A. P. Brush of the Brush Engineering Assn.

Discuss Difficulties

The speakers confined themselves mainly to a discussion of the difficulties of the problem, and it is hardly possible to say that any very definite conclusions were reached as a result of the meeting. There is no question, however, but that is was very valuable since a number of different viewpoints on the same subjects were explained so fully.

The major portion of Professor Berry's paper describing his experiments follows:

The carbureter performance is so often interpreted in terms of engine performance that it seems to me we ought to have a better standard of performance than this. To arrive at such a standard, we ran a series of tests at the university, undertaking to show the change in effect of gasoline and air mixture on performance. We tried to find what mixture gave the most economy and what mixture the most power, and the results of this I wish to report this evening. Before I do that, however, I want to enumerate the three requirements that it appears to me a carbureter should meet in order to give perfect performance, the three requirements our imaginary perfect carbureter would meet, as well as many other detail ones.

In the first place, it should be a good mixing valve; that is, the gasoline should be very thoroughly atomized. That is absolutely necessary. Future work may find another way of getting the mixture without this, but at the present time a good atomizing carbureter is superior.

Second, we want to get the proper amount of heat into the mixture. The first requirement, then, is to get gasoline and air thoroughly mixed in such a way that the mixture will get to the cylinder in exactly the same proportion as it left the carbureter. The carbureter must not cut down the volumetric efficiency. One case where it would do this is where it does not get to the throttle at atmospheric pressure. Then the mixture must not be heated. If it is heated at all, it cuts down the volumetric efficiency. The perfect carbureter will not do that. Third, the carbureter must furnish the engine with exactly that mixture which will give best performance at each speed and each load throughout the entire motor range.

The Best Mixture

The next question is, what is this mixture, and how does it vary? Do we need a rich mixture for idling, and a lean one for speed? Many experts seem to think both are needed, and there is another class that says neither is correct; that they want the same mixture for all speeds and at all loads. Which one is right? Does the mixture which gives the best power give the best efficiency? If not, how much difference is there between the mixture which gives best power and that which gives best efficiency? It is in an attempt to answer these questions that we have run these tests.

We had a six-cylinder engine, with the intake manifold inside. This helped to maintain a dry manifold and gave a satisfactory performance under circumstances which were adverse. The engine would idle, and hit every cylinder with very poor mixture.

We ran this test at 400, 700, 1000, 1300

Corcoran Mfg. Co. Expands

Buys Properties of Two Cincinnati Concerns and Will Build Body Plant

CINCINNATI, OHIO, Dec. 14—The Corcoran Mfg. Co., maker of automobile bodies, fenders, hoods and radiators, has bought the properties of the Jacob Freund Roofing Co. and the Cincinnati Tile and Terra Cotta Co.

The company is planning the construction of a fireproof building of four stories, 472 by 76 ft., to be used for the exclusive manufacture of automobile bodies. This will give employment to 500 men and will cost approximately $125,000.

When the company was formed, about 6 months ago, the result of the sale of the present officers' interests in the Corcoran and Victor corporations, it leased the manufacturing property at Winton Place. This lease does not expire for 3 years, at which time the company will erect a duplicate of the building now to be built, which will make the total plant area approximately 275,000 sq. ft.

—

Doehler Adopts 10 Per Cent Wage Dividend for Employees

BROOKLYN, N. Y., Dec. 16—Beginning Jan. 1, 1917, the Doehler Die-Casting Co. will declare a wage dividend at the rate of 10 per cent yearly to employees who have been with the company a year whenever the regular quarterly dividend on the stock is declared. The wage dividend, when declared, will be paid in full to employees with the company for over 3 years; two-thirds will be paid to those with the company from 2 to 3 years; and one-third for employees of 1 to 2 years' service.

Also beginning Jan. 1 employees who have been working on a basis of 50 hr. per week will be put on a 48-hr. basis at the same pay. The company employs 1200 men with a weekly pay roll of $25,000.

These announcements were made at a complimentary dinner last night tendered to the Doehler Executive Club, composed of all executive heads of the company, which has factories at Brooklyn, Newark, N. J., and Toledo.

—

Johns-Manville Gives Employees 10 Per Cent Bonus

NEW YORK, Dec. 20—Employees of the H. W. Johns-Manville Co. with the company a year or more received Christmas greetings signed by President T. F. Manville announcing the board of directors' decision to give a bonus equal to 10 per cent of the year's salary.

—

Princess Motor Corp. Now

DETROIT, Dec. 19—The Princess Motor Corp. of Delaware has been admitted to do business in the State of Michigan and has taken over the Princess Motor Co., which has heretofore handled the Michigan sales. Officers of the corporation are: O. C. White, president and managing director; I. N. White, vice-president and treasurer; H. C. Dawson, assistant sales and advertising manager.

—

Comet Buys Plant Site

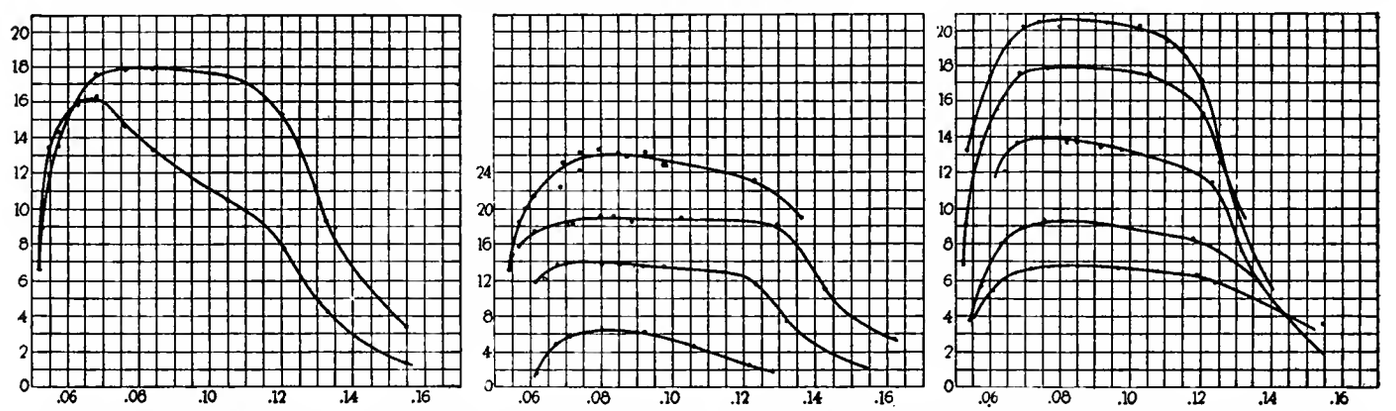
DECATUR, ILL., Dec. 18—The Comet Automobile Co. recently incorporated for $1,000,000 has purchased 20 acres of land upon which it plans to erect a factory and build a six-cylinder car to sell at $1,000.

—

Livingston Receives Perpetual Injunction

NEW YORK, Dec. 16—A decree of perpetual injunction carrying costs and reference to a master of accounting for assessment of damages has been signed in favor of D. McRa Livingston and his licensee, the Ospeco Mfg. Co. against the Lowe Motor Supplies Co.

As reported in THE AUTOMOBILE for Nov. 23, the suit alleged that the Lawco



Figs. 1, 2 and 3, reading from left to right. Fig. 1 shows horsepower curves as the mixture strength varies from .05 to .16 lb. of gasoline to 1 lb. of dry air. Fig. 2 and Fig. 3 show similar curves taken at different speeds and loads. All the curves show the mixture has a great effect on power, but that there is a "flat" period where slight variation in mixture does not greatly affect the power

radiator shell and hood made by the F. H. Lawson Co., Cincinnati, Ohio, and sold by the Lowe concern infringed the Livingston patent No. 1,156,017 covering a mask for concealing the engine and radiator casing of a car. Judge Sheppard held the patent valid and infringed, although commenting that no wilful infringement was evident. The case was in the U. S. District Court for the Southern District of New York.

—

Nelson Builds Four at $2,350

DETROIT, Dec. 20—E. A. Nelson, designer of Hupmobile models 20 and 32, has started the manufacture of a high quality light weight four, selling at $2,350 with a sedan body. The enterprise is financed by Mr. Nelson and the plant has a capacity of ten cars per day. Dealers have been closed in the principal eastern centers and cars shipped. The car incorporates a 3⅛ by 4¾-in. overhead camshaft engine with clutch, gearset and axle in a unit. It is designed for high economy and low grade gasoline, a mileage of 25 and better to the gallon being guaranteed; acceleration is 5 to 35 m.p.h. in 13½ sec. Wheelbase is 104 in. and the cord tires are 32 by 4. Carbureter is a Zenith, and starter is U-S-L. The entire car will be made in the Nelson plant.

—

Globe Tire Co. Buys Plant

LAPORTE, IND., Dec. 19—The Globe Tire Co., a corporation capitalized at $2,500,000, has bought the plant of the H. B. Glover Co. A. A. Peterson, formerly assistant superintendent of the Fiske Rubber Co., who will be superintendent of the plant, states that the company expects to have the plant in operation by March 1 manufacturing semi-solid rubber tires and inner tubes.

—

Hutchinson to Make Truck Equipment

MILWAUKEE, Dec. 16—R. W. Hutchinson, for the past 3 years general sales and advertising manager for the Sterling Motor Truck Co., Milwaukee, and its predecessors, the Sternberg Mfg. Co. and Sternberg Motor Truck Co., has resigned, effective Feb. 1, to devote himself to the manufacture of motor truck efficiency auxiliary equipment.

—

New Company Takes Schmid-Lyon

DETROIT, Dec. 18—Ossian G. Lyon has taken out papers for a new rubber concern at Akron, Ohio, with a $150,000 capital. The new organization will take over the factory buildings and business of the Schmid-Lyon Rubber Co. Mr. Lyon, who is the president of the new concern, states that it is planned to widely extend the business.

Line Drive Tractor Factory

—

$1,000,000 Company Plans To Establish Permanent Plant at South Milwaukee

MILWAUKEE, Dec. 18—The Line Drive Tractor Co., Pierre, S. D., organized recently with $1,000,000 capital and financed to a large extent by Milwaukee capital, is preparing to establish its permanent factory at South Milwaukee. Materials have been purchased for the initial issue of 1200 machines, which are unique because steering and operation is manipulated by a pair of lines, the operator being seated on the wagon, implement or vehicle being drawn by the tractor. The organization includes the following well-known engineers: David E. Ross, of the Ross Tool & Gear Co., Lafayette, Ind., chief consulting engineer; I. W. Davis, superintendent of the Stowell Co., South Milwaukee, superintendent of construction; R. S. Strader, manager of the service department. Mr. Strader for eight years was associated with the M. Rumely Co., Hart-Parr Co. and Detroit Tractor Co.

—

Brunswick Tire Plant Nearly Ready

MUSKEGON, MICH., Dec. 20—The Brunswick-Balke-Collender Co., by Jan. 15 will be manufacturing Brunswick tires and tubes at the rate of 500 per day. Before that date the new buildings will be completed and the machinery installed. Already the superintendents for the different departments of the factory are on hand and the manufacturing organization practically completed. In addition to manufacturing tires and tubes a line of rubber accessories will be produced.

—

K. W. Ignition Buys Land

CLEVELAND, Dec. 15—The K. W. Ignition Co. has purchased a parcel of land adjoining the company's plant. The recently acquired land is 60 by 245 ft.

—

Willard to Erect New Building

CLEVELAND, Dec. 18—The Willard Storage Battery Co. will erect a factory building to cost $35,000, and a storage building at $7000.

—

Reo Employees Co-operate to Reduce Cost of Living

LANSING, MICH., Dec. 16—More than 4500 employees of the Reo Motor Car Co. are experimenting with a co-operative purchase plan in an endeavor to reduce the cost of living. The first experiment was the purchase of two carloads of potatoes which effected a saving of 25 per cent above all cost. The workers are now bargaining for several carloads of canned goods which will be sold to the individual employees in case lots from the cars. Plans for a co-operative coal yard and general store are contemplated.

—

Harrison With Harroun

DETROIT, Dec. 14—John B. S. Harrison has been appointed the manager of the foreign department of the Harroun Motors Corp. Mr. Harrison was formerly a member of the United States embassy at Rome.

—

Republic Workers Have Co-operative Store

DETROIT, Dec. 16—The employees of the Republic Motor Truck Co., Alma, Mich., have organized a co-operative store which will purchase every kind of merchandise for its 900 members.

—

New International Rubber Sales Co.

LOUISVILLE, KY., Dec. 16—The New Tread Tyre Co. has changed its name to the International Rubber Sales Co.

—

Shaler Acquires Vulcanizer Patents

WAUPUN, WIS., Dec. 18—The C. A. Shaler Co., this city, has absorbed the vulcanizer business of the 5-Minute Vulcanizer Co., Kansas City, and the Vulcan Mfg. Co., Denver. The Shaler company states that it has recently acquired from W. H. Miles of Longton, England, and A. B. Low, of Denver, three basic patents, covering types of vulcanizers in which a solid fuel is used to produce the heat.

—

Parker Rust Proof Buys Patents

DETROIT, Dec. 14—The Parker Rust Proof Co. of America has completed negotiations for the purchase of the Thomas Watts Coslett patents No. 870,937 and No. 1,007,069, and all other improvements which may be made in rust proofing by Mr. Coslett. This purchase, according to officials of the Parker Rust Proof Co., gives that company control of the entire rust proofing art.

—

Lytle Joins Anderson Motor Co.

ROCK HILL, S. C., Dec. 15—R. W. Lytle has joined the Anderson Motor Co., this city, as production manager. He was formerly engineer and production of the Bimel Automobile Co., Sidney, Ohio.

—

Peerless Asks New Trial

CLEVELAND, Dec. 20—The Peerless Motor Car Co. has asked for a new trial of the suit brought against it by Henry S. Chapman for $800,000 alleging violation of contract. A verdict of $375,000 with interest, totaling $412,812, was recently awarded Chapman.

154,525 Overland Cars Sold

More Than 6,500 Dealers and Guests Entertained at 2-Weeks Convention

TOLEDO, Dec. 16—Contracts totaling 154,525 automobiles with a value of $131,346,250 have been signed during the first two weeks of the Willys-Overland Co.'s dealers' convention. More than 6500 dealers and guests have been entertained during that length of time.

The business of this past week, amounting to 66,975 cars with a value of $56,928,750, was received from dealers from the zones of the Middle West, New England and the South. The first group ordered 29,200 cars, the second 24,025 and the third 13,700 cars. The convention will come to a close next week. The South Dakota, Minnesota, Wisconsin and Eastern Iowa dealers will visit the company on Monday and Tuesday, and the New York, Indianapolis, Cincinnati, Lexington, Louisville, Lima and Evansville dealers will bring the event to its end on Wednesday and Thursday.

The most important feature of this week, aside from the industrial achievements was a parade held on Thursday, when the various guests and many employees joined a march, with many novel floats, through the city. More than $150,000 worth of cars were used.

Kelly-Springfield Tire May Show 40 per Cent for Common

NEW YORK, Dec. 20—The Kelly-Springfield Tire Co., it is stated, will show earnings of at least 40 per cent for its $5,000,000 common stock. This compares with 29.67 per cent in 1915. Earnings of 40 per cent would be two and one-half times the present dividend rate.

$10,500,000 Profits for Studebaker

DETROIT, Dec. 20—The Studebaker Corp., this city, it is stated, will show profits of between $10,500,000 and $10,800,000 during its fiscal year ending Dec. 31. The smaller figure is equal to 32 per cent on the $30,000,000 common after taking out the approximately required $800,000 for the preferred dividend on $10,965,000 stock. This compares with 27.4 per cent for the common stock in 1915.

Willys Addresses Insurance Presidents

TOLEDO, Dec. 15—John N. Willys, president of the Willys-Overland Co., accepted the invitation of the Association of Life Insurance Presidents and appeared before that body last night, with an address on the public services and patriotism of the American business man. In the course of his speech, Mr. Willys pointed out the vast growth of the automobile industry, assured his listeners that, in event of war, the automobile makers could be relied upon to use their machinery and factories for defense, and showed how France had twice been saved by automobile. He spoke optimistically of the future following the war, and dwelt at length on the vast welfare wrought to every human being by the automobile.

Governors Plan Uniform Laws for Pa., N. J., Md. and Del.

WILMINGTON, DEL., Dec. 18—Governor Charles R. Miller and Secretary of State George H. Hall of Delaware a few days ago attended a conference of similar officials representing Pennsylvania, New Jersey and Maryland, which was held in Philadelphia, the purpose being to consider the matter of uniform motor laws for the four States.

A thorough understanding was reached, according to one of those who attended the conference, and it is believed that the desired object will be accomplished in the near future.

To License Repair Men

DETROIT, Dec. 18 — Representative Charles W. Clark of Michigan, is planning to introduce a bill in the State Legislature which will provide for the licensing of all garage men who are employed in automobile repair work.

Inasmuch as every member of the Legislature is a car owner it is believed that he has an excellent chance of getting his proposed bill passed in the next session.

$70,000,000 Sales for Goodrich

AKRON, Dec. 15—Sales of the B. F. Goodrich Co. for 1916 will total nearly $70,000,000, as compared with 56,000,000 in 1915 and $43,000,000 in 1914. Earnings in the first 6 months of this year amounted to 6½ per cent on the $60,000,000 common.

G. M. C. Certificates Listed

Temporary Certificates on N.Y. Stock Exchange Balance Sheet as of Dec. 9.

NEW YORK, Dec. 19—The temporary certificates of the General Motors Corp., of $20,000,000 preferred and $82,600,000 common, have been listed on the Stock Exchange. The corporation was formed to take over the stock of the General Motors Co. Of the $45,314,000 common of the corporation outstanding on Dec. 9, the Chevrolet company held $16,644,500 in its treasury in one certificate.

It is also stated that the Chevrolet Motor Co. agrees that the shares of common stock of the General Motors Corp. acquired by it will be kept in its treasury and that the Chevrolet Motor Co. will not part in any manner with any of these shares without first publishing notice of its intention to do so at least 60 days in advance.

The balance sheet of the General Motors Corp. of Delaware as of Dec. 9, 1916, appears herewith:

Pyrene to Increase Capital

NEW YORK, Dec. 20—The Pyrene Mfg. Co., this city, has called a meeting of the stockholders on Jan. 2, at which action will be taken on a proposed increase of capital from $1,050,000, divided into 100,000 shares of common, and 5000 shares of preferred, each to $3,050,000 divided into 300,000 shares of common of $10 par value, and 5000 shares of preferred, of $10 par value.

Simplex Capital Now $9,000,000

DOVER, DEL., Dec. 15—The Simplex Automobile Co. of New York has increased its capital from $5,000,000 to $9,000,000.

Dixie Increases Capital to $400,000

LOUISVILLE, KY., Dec. 16—The Dixie Motor Car Co. has increased its capital from $150,000 to $400,000, divided into 4000 shares of a par value of $100 and

Balance Sheet of General Motors Corp. of Delaware as of Dec. 9

Less amount to be exchanged for General Motors of New Jersey	37,285,900
Common outstanding	*$45,314,100
Bills payable	15,000
Accounts payable	25,904
Total	$57,551,004

*Of this amount $16,644,500 is owned by Chevrolet Motor Co. and held in its treasury in one certificate.

authorizing an indebtedness not to exceed $1,000,000. One-half of the stock is to be common and one-half preferred and the additional issue of 1000 shares of common is to be held in the treasury of the company and issued to the present owners of common stock as it is subscribed for them by them and paid for in cash.

The preferred stock is to pay 7 per cent dividends, one-half Jan. 1 and one-half July 1 of each year.

Midland Tire Capital Now $500,000

COSHOCTON, OHIO, Dec. 18—Papers have been filed with the Secretary of State increasing the authorized capital of the Midland Tire & Rubber Co., from $10,000 to $500,000. The concern has taken over the plant of the McClurg Tire Co.

Lockwood-Ash Increases Capital

JACKSON, MICH., Dec. 18—The Lockwood-Ash Motor Co., Jackson, Mich., has increased its capital stock from $20,000 to $150,000. A distribution of $89,500 surplus furnished the increase with a balance of $40,000 which will be left open for future needs.

East Palestine Capital $1,000,000

EAST PALESTINE, OHIO, Dec. 15—The East Palestine Rubber Co., this city, manufacturing tires, has increased its capital from $500,000 to $1,000,000 to take care of additions to the plant. A new building will be erected, 200 by 55 ft., and will have a capacity of 200 tires a day.

Warner Cuts Capital Stock

DETROIT, Dec. 16—The Warner Mfg. Co. of Toledo has reduced its capital stock from $500,000 to $50,000. The Toledo plant of this company was recently sold to the Chevrolet Motor Co.

Briggs-Detroiter Capital Reduced

DETROIT, Dec. 16—The Briggs-Detroiter Co. has decreased its capital stock from $200,000 to $2000, and has changed its name to the United Detroiter Corp.

Gasoline Goes Up 1 Cent

Advance Throughout Country —Standard Oil and Other Companies Join In

NEW YORK, Dec. 18—Gasoline is higher throughout the country, especially throughout the western States. As yet no rise has occurred along the Atlantic Coast. One-cent rises are reported from Chicago, Milwaukee, Tacoma, St. Louis, and Minneapolis.

The Standard Oil Co. of Indiana to-day advanced its tank wagon price 1 cent a gallon in Chicago to 17½ cents. In the Northwest prices are now quoting at 20½ cents at filling stations. This figure is a new record there. In the Twin Cities, gasoline is retailing at 17½ cents. This is the first advance since the agitation was begun for investigation of the gasoline situation. Standard Oil gasoline in St. Louis is quoting at 16.9 cents a gallon at stations and on tank wagons. Naphtha is selling at 16.4 cents. Independents have been selling gasoline for 17 cents. Pierce Oil Corp. is still selling gasoline in St. Louis for 15.9 cents a gallon, but an advance is expected soon.

Hayes Capitalization Plans Perfected

DETROIT, Dec. 18—If the present plans of the Hayes Mfg. Co. are approved, stockholders will receive a stock dividend of 75 per cent, as it is proposed to increase the capital to $1,750,000 of which $250,000 will be 7 per cent cumulative preferred stock. Under the plan the present preferred stock will be retired.

Westinghouse Limits Stock Subscription

CLEVELAND, Dec. 15—Notices will be sent to Westinghouse Electric stockholders shortly after Dec. 30, specifying the amount of stock to which the stockholder is entitled to subscribe. Warrants entitling the holder to subscribe will be issued only for amount of $50 or multiples thereof. For each fraction of a share, a fractional warrant or fractional warrants will be issued. After Feb. 19, 1917, fractional warrants will be void. No subscription may be made on a fractional warrant but if surrendered on or before Feb. 19, 1917, to the United States Mortgage & Trust Co. with other fractional warrants aggregating at least $50, a subscription warrant for one share will be issued in exchange.

United Motors Co. Raises Capital

DETROIT, Dec. 18—The United Motors Co. of Grand Rapids, has increased its capital from $1000 to $750,000. The increase has been paid in in cash by the incorporators, and officials of the company state that the concern is in excellent financial standing with no bonded or floating debts. Officers of the company recently elected, are: Frank D. Hulswit, president; George P. Sweet, vice-president; H. R. Green, treasurer; L. H. Einke, secretary, and K. A. Myers, assistant treasurer.

Two Companies Will Pay Off $4,000,000

DETROIT, Dec. 18—The Youngstown Sheet & Tube Co. and the Brier Hill Steel and Trumbull Steel companies will pay off bonds totaling $4,000,000, canceling all of their outstanding surplus of the character in January. They will also grant employees a 10 per cent advance, the third for the year, which will contribute approximately $600,000 to the workers.

Material Prices Drop

NEW YORK, Dec. 18—Materials dropped considerably in price last week. Copper went down 1 cent to 34 cents a lb., lead dropped to $7.63, a loss of 47 cents per 100 lb., both Para and Ceylon grades of rubber closed yesterday lower, and tin was also lower. Only one gain occurred and that was Kansas crude, which rose to $1.20 per barrel, a gain of 10 cents.

Fostoria Co. to Change Name

DETROIT, Dec. 18—The Fostoria Light Car Co. stockholders will meet Jan. 8 to reorganize the company and elect new officers, besides changing the name of the concern to the Seneca Motor Car Co.

McCord Assets $1,875,000

NEW YORK, Dec. 20—The McCord Mfg. Co., Detroit, maker of automobile radiators, which last week authorized an issue of $1,000,000 of 7 per cent cumulative preferred stock and 75,000 shares of common stock, no par value, reports net tangible assets over $1,875,000, or two and one-half times the preferred issue. Net quick assets alone are $1,000,-

000, or one and one-third times the preferred issue.

Net earnings for 12 months ended Oct. 31, 1916, were over $563,000 or more than ten and one-half times the preferred dividend requirements. In 1915 the company did a business amounting to $2,569,051, and earnings amounted to $324,472.

The company was organized in 1909 and has increased its plant space from 40,000 sq. ft. to approximately 300,000 sq. ft., with a capacity of 2000 radiators a day. It also manufactures gaskets for steam and gas engines, lubricators, etc.

Dividends Declared

Electric Storage Battery Co., 1 per cent from net earnings on both common and preferred, payable Jan. 2 to stock of record Dec. 18.

Keystone Tire & Rubber Co., quarterly of 3 per cent on common and 2 per cent and an extra of 1-3 of 1 per cent on preferred. Three months ago the company declared quarterly of 2 per cent and extra of ¾ of 1 per cent on common and quarterly of 2 per cent and extra of ¼ of 1 per cent on preferred.

National Carbon Co., quarterly of 2 per cent and extra of 2 per cent on common, payable Jan. 15 to holders of record Jan. 15.

Pyrene Mfg. Co., 2½ per cent on common, payable Feb. 1, 1917, to stock of record Jan. 25, 1917.

Saxon Motor Car Corp., 1¾ per cent, payable Jan. 17 to stock of record of Jan. 3.

Big Drop in Motor Securities

General Motors Down 50 Points—United Motors Falls 93¾—Fisk Strong

NEW YORK, Dec. 18—The automobile issues joined in the general slump of stocks which has for the past two weeks been the cause of heavy losses in speculation. With few exceptions was there any tendency toward strength in the issues. Not only was there liquidation in the automobile issues but also in the tire stocks.

One of the most prominent drops last week was that of General Motors, which went down to 600, a loss of 50 points. Another stock, which has been speculated on to a great extent, but which has failed to hold up to the estimation predicted for it, is United Motors. This stock is one of the strongest in point of assets on the motor securities market, yet it has failed to show any material strength during the present slump. Yesterday it quoted at 49¾, as against 69 several months ago. Willys-Overland has been holding better lately. Chevrolet, on the other hand, probably in sympathy with the General Motors slump, has fallen down to 142, a drop of 28 points in the past week.

Tire issues were in the majority of cases lower. Ajax went down 6⅛ points; Goodrich common dropped 4⅜ points and the preferred 2½ points; Goodyear common dropped 3 points; Firestone went down 15 points to 135, and United States Rubber common dropped 3¼ points.

Winther Truck Elects Officers

KENOSHA, WIS., Dec. 18—The Winther Motor Truck Co., Kenosha, Wis., organized recently with $300,000 capital to manufacture motor trucks, has perfected its organization with the election of these officers: President and general manager, Martin P. Winther; vice-president and factory manager, William Martinson; secretary, treasurer and sales manager, Walter D. Rightmire; directors, M. P. Winther, William Martinson, W. D. Rightmire, Jerry W. DeCou and Walter M. Burke. The truck will be known as the Winther. A specialty will be made of fire-fighting apparatus, and the Winther company has effected an alliance with the Peter Pirsch Co., Kenosha, Wis., fire apparatus, for the joint production of such cars, to be trademarked Pirsch-Winther. A factory will be erected by the Winther company immediately on a 4-acre site just purchased at the western limits of Kenosha.

Temple of Flowers for New York Show

NEW YORK, Dec. 18—The Temple of Flowers is the theme selected by Manager S. A. Miles, of the N. A. C. C., for the decorative plan of the New York Show at Grand Central Palace.

ers of varied hue are to be used at the base of the giant marble columns on the main floor of the building. From the boxes will issue trailing vines which will reach to the top of the columns and twine about huge floral baskets of Roman type. A window frame of colonial design will be installed at each window on the main floor and behind the frame will be hung scenic paintings which will give the visitor the impression of looking outdoors. Dotting the walls between the windows will be installed a number of large mirrors and the reflection of the cars in these will add breadth to the interior. At the rear of the building huge draperies will hang, giving a rich background effect to the decorative plan.

The lobby to the Palace will be decorated with bay trees and flowers. Six large scenic paintings will be hung on the walls of the lobby.

The signs of the exhibitors will be made up of white letters on a red background in a gold border. The colors of the show will be white and green with red much in evidence.

Spark Plug Men Meet

DETROIT, Dec. 19—The fourth annual convention of Champion spark plug salesmen opened in Toledo yesterday, with visitors from all parts of the country. The convention will last for 4 days and the guests will include lectures, trips through the factory, luncheons and a huge banquet among their activities.

The company plans an output of 75,000 spark plugs per day during the next year and expects to instill highest efficiency selling principles in the salesmen to insure correct handling of such a large production.

—

Sparks-Withington Cleveland Branch

CLEVELAND, Dec. 18—The Sparks-Withington Co., Jackson, Mich., will maintain a branch office in Cleveland. A. A. O'Reilly will be in charge.

—

Nichoalds Branch in Indianapolis

DETROIT, Dec. 18—The Nichoalds Co., Detroit, retailer and jobber in motor car parts and accessories, will open a branch in Indianapolis Jan. 2. T. A. Nichoalds will be branch manager.

—

Renfro Sparks-Withington Sales Agent

JACKSON, MICH., Dec. 16—The Sparks-Withington Co., this city, has selected J. F. Renfro as Eastern Sales Agent, with offices at 1834 Broadway, New York, becoming effective Dec. 15. His territory comprises New York, Pennsylvania, New Jersey, Delaware, Maryland, Virginia and the District of Columbia. Mr. Renfro has been connected with the selling branch of the industry for a number of years.

Tire Prices Soon to Increase

—

20% Rise Expected, Due to Increased Cost of Materials and Manufacture

NEW YORK, Dec. 18—The rise in the prices of tires, threatened for the past few weeks, is not far off, according to the rubber trade in general. Prices are expected to go up at least 20 per cent. The material scarcity and their unprecedented prices have been the main reasons for the rise. Though rubber has not risen exorbitantly, the other materials which go into the makeup of tires have risen on an average about 20 per cent. For instance, tire fabric, one of the important parts of the tire, has risen in price about 100 per cent. Chemicals, cotton, labor, rent, shipping conditions, all have had their potent effect on prices.

Advise Immediate Purchase

A few of the tire companies are looking to the future by advising their dealers to get in their tires immediately. One prominent concern is taking no large orders, but advises its dealers to buy at present prices.

One of the largest companies is guaranteeing its prices for three months. Other concerns state that there is no logical reason why prices should not go up at the present time, that they are waiting for some company to take the initiative in the matter. And for that reason some of them are not accepting orders for future delivery at guaranteed prices.

The high cost of fabric has been largely responsible for the threatened rise. Tire fabric has gone up on account of the big scarcity of Egyptian and Sea Island cotton, two of the most popular grades used. Submarine warfare, weather conditions, and manipulation on the Alexandrian Exchange were responsible for a big rise in Egyptian cotton. Great Britain is largely in control of the Sea Island cotton, which is mainly contracted for before the American tire makers or duck makers have a chance to buy. These conditions, together with the cotton scarcity along the Atlantic Coast, naturally caused an increase. The cotton along the Atlantic Coast, in the Carolinas and Virginia, is the only grade in this country that is suited for tire manufacture.

—

Eleventh Edition National Used Car Report

CHICAGO, Dec. 18—The eleventh edition of the National Used Car Market Report has been issued by the Chicago Automobile Trade Association. Zone 11, centering in Dallas, is still missing.

New names in the list are: Arbenz, Biddle, Bour-Davis, Cameron, Daniels, Dispatch, Dixie, Elcar, Elgin, Hackett, Hollier, Jordan, Laurel, Madison, McIntyre, Monitor, Monroe, Owen Magnetic, Roamer, Singer, Spaulding, Sun and Woods Gas-Electric. There are 163 gasoline cars and 15 electrics listed, as compared with 139 gas and 14 electrics in the tenth addition. The pocket edition accompanies the larger edition, containing the data in abbreviated form.

—

National Rubber Co. Increases Mileage Guarantee

POTTSTOWN, PA., Dec. 16—For 1917 the National Rubber Co., this city, is placing on the market a new gray tread speedway tire which will be guaranteed on the basis of 5000 miles' service.

The list price of the new tire will be slightly higher than its ebony tread speedway, but because of the larger mileage guarantee the price of the new tire is actually less, when figured from the mileage viewpoint.

The company does not contemplate any increase in the price of its new gray tread tire.

—

Dunlop Originated Cycle Tire

NEW YORK, Dec. 14—The Michelin Tire Co. advises us that in an advertisement of theirs appearing in a recent issue of THE AUTOMOBILE, it was stated that Michelin invented the bicycle tire. This was a mistake. What should have been said was, the first detachable bicycle tire. The invention of the pneumatic tire dates back to the middle of the last century, and J. B. Dunlop originated the first successful pneumatic bicycle tire in Ireland in 1888.

—

Gerlinger Tractor Attachment for $275

TACOMA, WASH., Dec. 16—The Gerlinger Motor Car Co., Tacoma, has placed a tractor attachment on the market which may be attached to any small car. The price is $275. It is known as the Universal tractor attachment.

—

To Build Trucks in Cork

MANCHESTER, ENGLAND, Dec. 10—The city park of Cork, Ireland, is to be used for the manufacture of commercial vehicles. The Trafford Engineering Co., this city, has taken an option on that park upon which it will erect a plant to cost between $1,000,000 and $2,000,000. The company plans the manufacture of worm-drive trucks on a large scale. It will employ 2000 men.

—

J. W. Packard Presides Over Buffalo Co.

DETROIT, Dec. 16—J. W. Packard has been elected president of the Packard Buffalo Motor Co., Inc., which recently purchased the Buffalo interests of the Packard Motor Car Co., of New York.

Mr. Packard owned the small electrical shop at Warren, Ohio, where the first Packard car was made. He was the first president of the Packard Motor Car Co. and was later chairman of the board of directors. Four years ago he resigned and retired to Lakewood, N. J. The Packard Buffalo company is the result of financial aid from Mr. Packard and his brother, W. D. Packard. It will be managed by B. C. Day, who was formerly in charge of the Buffalo branch for the Packard Motor Car Co., of New York.

—

Hare Heads N. Y. Packard

NEW YORK, Dec. 16—Emlen S. Hare, formerly general manager of the New York branch of the Packard Motor Car Co., has been promoted to the head of that organization. L. J. Eastman has been elected as president and director of the Packard Motor Car Co. of Philadelphia.

—

Paige Distributers at Factory

DETROIT, Dec. 16—More than forty of the principal distributers of the Paige cars in the United States were visitors at the factory of the Paige-Detroit Motor Car Co. this past week. They witnessed the unveiling of the new models, listened to addresses made by Harry M. Jewett, president of the company, Henry Krohn, sales manager, and others, and spent a part of the time inspecting the factory, merchandising plans and efficiency and sales promotion work.

—

Not a Kent Representative

NEW YORK, Dec. 18.—Readers of THE AUTOMOBILE should beware of a man representing himself as the authorized agent of the Kent Motors Corp., to appoint territorial agents to whom a car was to be sent on consignment on payment of $5. The Kent corporation has no traveling representative. Before paying any money to so called agents of car manufacturers, it is best to communicate with the home office of the company on the matter.

—

Studebaker Dealers in Grand Rapids

DETROIT, Dec. 18—Forty-six Studebaker dealers from Western Michigan, units of the Becker Motor Car Co., Grand Rapids, met last week in that city, for a banquet and business discussion.

—

Herreshoff Co. in Bristol, R. I.

NEW YORK, Dec. 18—In THE AUTOMOBILE for Dec. 7, the location of the Herreshoff Mfg. Co., maker of the Novara car, was given as Bristol, Conn., whereas it should have been Bristol, R. I.

May Run 500-Mile at Cincinnati

—

Overcharging of Automobilists by Indianapolis Hotel Keepers May Cause Shift

INDIANAPOLIS, IND., Dec. 19—Carl G. Fisher, president of the Indianapolis Motor Speedway, announces he is considering plans for staging the annual 500-mile international sweepstakes race at the Cincinnati Motor Speedway on Memorial Day, because of the treatment accorded automobilists in Indianapolis by hotel keepers. Fisher is incensed because hotel owners have insisted on charging motorists who come here to attend the races as high as $25 a day for rooms for which the charge normally is from $2 to $4. He declared the speedway management can make as much if not more money by staging the race in Cincinnati. Fisher declared the attitude of Indianapolis hotel keepers has given the city a black eye with motorists throughout the entire country.

—

Indiana S. A. E. Talks Carburetion

(*Continued from page* 1037)

and 1600 r.p.m., with 100 lb. on the brake at full load.

We ran it with one-fourth load, one-half, three-quarters and full load. At each condition, say at 1300 revolutions, and 50 lb. brake load, we changed the mixture in the carbureter arbitrarily by changing the gasoline needle valve until the mixture was very lean, and kept increasing it until we got the engine running under the most powerful mixture—until we got to the point where the mixture would not increase the power of the motor at the same opening of the throttle.

After we got to 1300 revolutions and 50-lb. brake load we kept the throttle opening the same, and changed our brake load so as to hold the speed constant. We had the apparatus so arranged that we could weigh our gasoline to 1/100 part of an ounce. We metered the air and took the temperature into the meter and out. The vacuum was recorded and the humidity of the air was recorded, so we made an attempt to find out just how much dry air was used in each case. At the time it came to a balance it rang a gong and started a revolution counter on the end of the shaft, and then we took off the weights and set the switch again. Then, when it balanced again, it rang the gong, stopped the watch, and we knew the amount of air within 1 per cent, and knew the amount of gasoline to 1/100 part of an ounce. We recorded the amount of air, the temperature, pressure and humidity, the amount of gasoline used, and the power developed, and then we made a run.

We increased the mixture and got point No. 2, Fig. 1, and made a series of tests that way, increasing the gas in the mixture until the engine would no longer run. The curve, Fig. 1, shows the change in power due to the change in gasoline in the mixture; 0.05 of a pound of gasoline per pound of dry air, up to 16 hundredths pounds of gasoline per pound of dry air. We have very accurate figures. The perfect mixture is 0.0671 lb. gasoline to 1 lb. dry air.

The power is not quite maximum at the theoretically perfect mixture. For the range of mixtures you can get good power at 0.06 and still get good power at 0.12. You can double the amount of gasoline in the mixture and still carry almost full load, and I was unable to train myself so I could stand beside the engine and tell where in that range the motor was running. I could not tell by sound whether the engine was on the lean or the rich end.

The next point is the effect on efficiency. In all of these curves for all running conditions we have found the maximum efficiency seemed to be exactly at the point of the theoretically perfect mixture. Below perfect mixture the efficiency dropped off. If you increase above that your power drops off.

New Klaxon Three at $3

NEWARK, N. J., Nov. 6—The Klaxon Three, selling at $3, will be brought out Jan. 1 by the Klaxon Co., this city. It will operate on the push-from-behind principle. The push-from-the top principle which has heretofore been used in the Klaxon, has been abandoned in all models.

Upon the completion of a large addition now in process of construction, the Klaxon plant will be doubled in capacity. For 1917 the company announces a reduction in the number of models which it has made in the past. All facilities will be concentrated on a few standard models to be known as Klaxon 20, selling for $20; Klaxon 12, designed especially for use under the hood; Klaxon 6, a smaller electric horn for both outside and under-hood use at $6; and the new Klaxon Three.

Better Cars

IN summing up all the changes in engineering noted on the 1917 cars there is but a paltry total if the design changes of last year are compared with those of the present one. But design is only a part of the task of making good automobiles, and 1916 has been a banner year for the manufacturing side, which does work that is much less spectacular than that of the engineering departments.

There is no object in trying to blink the fact that some manufacturers have increased production at the expense of the quality of their cars, that some of the new systems and processes have exhibited troubles during the year, and that the vastly improved designs produced in 1915 have not always had the perfection of manufacture during 1916 of which they were worthy. But troubles as they arose have been caught in the early stages and the probability is that 1917 will be a year in which average workmanship will be improved very greatly, following the steady improvement that has been taking place throughout the year now drawing to a close.

When a huge new machine is set up—a big printing press, a large turbine, a ship's engines and so on—it is always some little time after first starting up that everything is running smoothly. Last year the automobile manufacturers re-created their factories, made bigger machines of them, and we have had the period of settling down to go through. We have now passed this period, or at least the worst of it, and can look forward confidently to better and even more economically made cars in 1917.

The Parking Problem

EVERY day in big cities the parking problem grows more acute. If it is bad to-day, and indeed it is so, what will be the situation in 3 years?

We are facing something which was never foreseen in the planning of our towns, a thing which has come upon us so swiftly that there has been no time to grasp the immensity of the problem till we are almost overcome by it.

At present we need some definite ideals to work for. The big cities are now trying to handle the matter by prohibiting parking in the main thoroughfares, but this is not a solution of the difficulty; it merely postpones the task of settling the thing properly and makes that settlement more difficult in the end.

One, almost ideal method is to have streets so wide that a central strip 30 to 40 ft. wide can be given over to parking, leaving enough road for traffic on either side, but obviously this can only be considered in very new towns with their future before them.

For existing big cities we have three schemes, large municipal garages, underground parking "cellars" and overhead roads. Of the three the first is not a good solution. To get the greatest benefit from the machine the automobile should be parked close to the place where its user is at the time. Very many scattered, small parking places are much better than a few immense garages.

There is one big opportunity for doing something with the huge garage and this is in the few biggest cities of all where transportation of all kinds is good. Here big garages just outside the congested area would be an immense advantage. In New York, for instance, they might be just off or just on Manhattan at the points where the main roads enter and link with the public service surface and subway systems.

The underground scheme has excessive cost against it, and also the need for perpetual artificial light and the probable difficulty of getting in and out. Yet, if we cannot widen our streets it seems the only other answer is to double then by going above or below. The elevated road would be costly, but it does seem to be the more plausible scheme.

The elevated road should be considered from the viewpoint of its advantage to through traffic. Take a city with a half dozen radial roads where it is necessary to cross town to get from one side to the other. In such places an elevated system would remove all through traffic from streets where the shopping and similar traffic abounds. Imagine Detroit with an overhead Woodward Avenue connecting to Jefferson and to several points on the Boulevard; an elevated road with no speed limit, solely for automobile traffic!

The subject needs much more discussion than it is getting. It cannot possibly be handled much longer by repressive legislation alone.

Austria-Hungary

By Edward Allen Langdon*

¶ All classes in Hungary have been enriched by the war, and when hostilities cease there will be a large demand for automobiles.

¶ Austria will need 150,000 passenger automobiles and 6000 trucks in the first 24 months following the close of the war.

¶ U. S. A. automobile firms will have to establish service stations in either Austria or Germany. They will have to be well stocked with spare parts.

¶ Hungary being primarily an agricultural country will need light automobiles and small farm tractors. Conditions are similar to that of the West and Middle West U. S. A.

¶ Austria-Hungary after the war will be on a basis of German efficiency.

So far as one can tell, by developments up to the present time, there will be hardly a country in Europe which will be so modernized by the war as Austria-Hungary. Already deep changes are noticeable, and no doubt this state will present, after the war, a set of conditions altogether different from what the dual monarchy was known as before 1914. Many of these changes are of very direct bearing on the question of Austria-Hungary as an automobile market, and the following remarks are devoted precisely to this question. If, after 2 years of warfare, the struggle is still going on unrelentingly, it seems nevertheless to most well-informed people not only in Central Europe, but also in the neutral countries of this continent that the end of the war is nearer than it would seem from its bitterness. For this reason, too much stress cannot be laid upon the advice to American manufacturers of automobiles, motor trucks, tires and accessories.

1500 People Per Car

The beginning of the war found Austria in the possession of perhaps 40,000 automobiles. Certainly, this was a small number for a nation of almost 60,000,000. But there was a reason, or rather, several good reasons; Austria-Hungary was, and still is, primarily an agricultural country, and in Europe this means a country none too progressive. Hence, modern machinery both in manufacture and transportation was introduced slowly. The horse played a very important rôle in the transportation of passengers and merchandise. The agricultural population, excepting the rich landowners, were partly not in a position to buy automobiles, and partly did they still mistrust this modern type of vehicle. The peasant in this country is much more conservative than the American farmer, or for that matter, the farming class of England and France. Hence, the rural sections were almost without motor vehicles, excepting where lumber mills and other large industrial undertakings utilized motor trucks.

Horses Are Fewer

All these conditions have changed. The supply of horses has been diminished, so that the importance of this factor in tractive work is much less than 3 years ago. In addition to this absolute decrease of importance, there must be considered the fact that the peasant class has more than any other class suffered from the troubles of war, is more than any other decimated and maimed and reduced in their ability to work. Hence, agriculture in the dual monarchy will *perforce* be put on a more modern basis of operation, wherein the work formerly done by two, three or four men will have to be done by one man, or a woman, for that matter; as women are now a factor of never before imagined importance in the life of Austria-Hungary.

So much for the need of small passenger automobiles, medium-sized trucks and tractors for the agricultural sections.

Government Provides Truck Subsidy

The industries of Austria began to take to automobiles even before the war, and this trend was enhanced by the policy of the government to subsidize purchasers of motor trucks made in Austria provided the trucks came up to certain governmental specifications so as to be useful in case of war. This policy will without a doubt be continued with increased energy when peace has been restored, and of course foreign-made automobiles (in all likelihood the subsidies will be extended to passenger cars also) will not receive the government support and therefore will have to compare favorably in price with the native product.

All the population has been educated in a broad way to modern appliances by the war. Soldiers, called from the farm, who never before had an opportunity to handle mechanical devices, have become interested and adept in the driving of automobiles. People have become accustomed, in this most comfortable country of Europe, to do their work on an

*Editor's Note—Edward Allen Langdon has for many months been in different parts of Europe studying automobile conditions in those countries. Mr. Langdon is a critical student of conditions. He is making a conservative study of trade and all his utterances savor of conservatism.

efficient-schedule basis, to be on time, to carry out their tasks with almost German or American precision. All these factors make for a psychologically better automobile market after the war.

Hungary Especially Important

Special attention should be given to Hungary. This part of the dual monarchy has very much increased in importance during the war and indeed is to-day more powerful than "the Kingdoms and Countries represented in Parliament," as the Austrian half of the realm is called officially. Hungary is primarily an agricultural country and fertile enough to feed all of Central Europe, with proper methods of distribution. But the country is also rich in mineral resources, and the past two decades have seen a rapid growth of industry there. The war is bound to accelerate this development, and as Hungary has been very much enriched, through all its classes, by the war, it ought to offer splendid opportunities to enterprising exporters of American cars.

Money Is Plentiful

The field here includes especially the very types of automobiles sought and bought by American farmers of the West and Middle West, also three-wheeled tractors suitable for connection to agricultural machines proper. It should also be noted that the end of the war will find money more plentiful in Hungary than in Austria.

It has been stated that women have become a highly important factor in social and economic life of Austria-Hungary. This means that cars hereafter will in many cases be operated by women, whereas before the war none except the ladies of the richest classes operated machines. It follows that, women being perhaps less ready to grasp mechanical details, the bulk of automobiles sold in Austria-Hungary will have to be fairly simple and yet reliable in construction.

Much Hill Work

Austria is to a very large extent mountainous, and passenger cars for touring purposes will have to be of a type suitable for alpine work, with good climbing ability, plenty of reserve power and fair fuel economy. The Austrian fuel, after the war, will be benzine—practically identical with American gasoline—although Germany will use alcohol and benzol extensively. Touring cars should be comfortable, strong and efficient, without being too heavy. The ideal type of Alpine car is the Austrian Daimler which in the last few Alpine tours made excellent showings; and by this standard Austrian tourists will measure the cars they buy. They will look for machines built along somewhat similar yet lighter lines, including the points aforementioned, and fitted if possible with large tires, as well as electric lighting and starting, all the necessary accessories and fixtures required for the particular class of touring.

Service Stations Are Essential

One point essential in selling cars in Austria-Hungary is that there must be a service station somewhere in Europe, capable of supplying within a few days any reserve parts needed. Very likely this service station will have to be located in either Austria or Germany, as it will be a long time until the Central European countries will forget the isolation created by the British blockade. This point of the necessity of a service station cannot be overemphasized.

The Road to the Orient

Another point is the knowledge of the native language by the salesman, and, of course, discretion and politeness, perhaps even diplomacy; for there are many people in Central Europe now who are anything but enthusiastic admirers of America.

If, as has been mentioned as probable, the end of the war is nearer than is generally supposed, then Austria-Hungary will take on importance in another new respect. At this writing there is practically an unbroken line of transit between Hamburg and Bagdad; and unless the fates of war change fundamentally in the future, Vienna will be the central point of the important bridge between industrial Germany and the progressing Near East. Austria-Hungary is bound, in such an evolution, to play an important role, and preparations are being made, financially and technically to fit her for playing it. This development alone, the rendering of the dual monarchy into a road to the Orient will necessarily lead to an increased prosperity of Austria-Hungary.

Industrial Efficiency to Grow

Judging by the degree to which Austrian affairs are now run, directly or indirectly, by Imperial German direction, it is very likely that Austria will rapidly advance to an industrial efficiency closely approaching that of Germany herself. In that case the prosperity of the rejuvenated dual monarchy will by far exceed the fairly conservative estimate given below. This estimate is for the automobile market's capacity, for the 24 months following the war, and presupposes a moderate regeneration which would be illustrated by an exchange rate on Austria of 15 to 16 cents for the Krone. From talks with members of the Austrian industries I should put the demand for the period mentioned at

150,000	passenger cars....	@ $ 700	$105,000,000
5,000	trucks	" 2,000	10,000,000
1,000	"	" 3,000	3,000,000
	Total		$118,000,000

Best Car-Marketing Plan

The prices marked would have to be f.o.b. New York, and wherever agencies are given to local dealers, transactions would have to be done on letter of credit for 4 months' sight. Automobiles would have to be guaranteed substantially.

As to the selling of cars in Austria-Hungary a few points have already been mentioned. The most advantageous method of utilizing the territory would be a central place in Vienna, and four or five branch salesrooms in Austria and one or two in Hungary. Perhaps the best plan would be for several makers to combine for the export of their products to Austria-Hungary so as to reduce the expense and use the saving for selling the machines at the best price possible.

Regarding the cost of such agencies, it is very difficult to lay down definite data, but a place in Vienna and moderate advertising can be had for $12,000 to $15,000 a year total expense. This makes possible a turnover of $60,000 to $80,000 for the same period.

U. S. A. Cars in Favor

Before the war, half a dozen or so of well-known medium-priced American cars were introduced very successfully in Austria-Hungary and while the supply of these cars was cut short by the outbreak of the war, many of these machines have rendered splendid service in the army and have served to create an excellent reputation for American cars regarding which many pople felt rather chary prior to the present calamity.

There has been a tariff on automobiles and it will very likely be continued after the war, perhaps even increased. If this is the case, the exporting to Austria-Hungary of automobile parts will pay even better than that of complete automobiles.

Good Tire and Accessory Field

There is also a splendid market for tires in this country, and while there are some Austrian and German makes on the market, American products, if properly handled, should be

able to replace them completely after the close of hostilities.

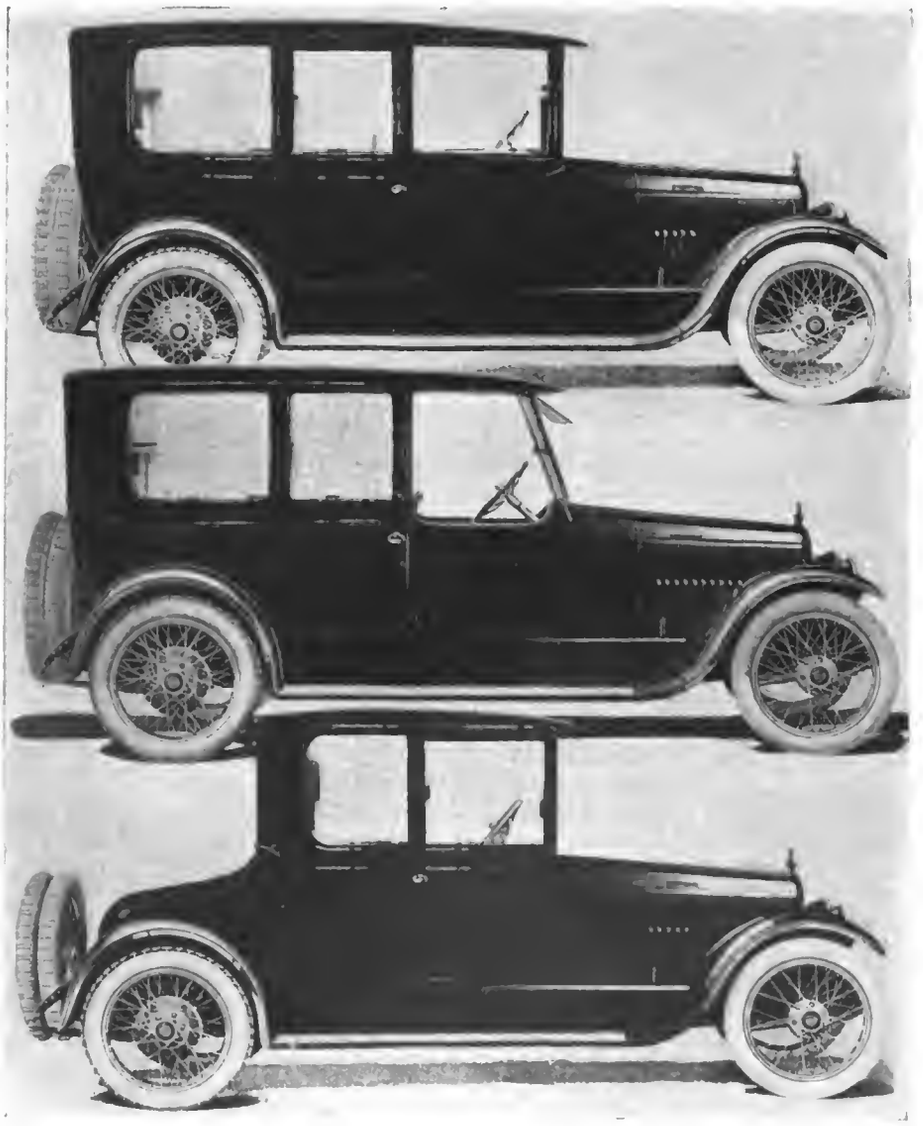
Likewise, accessories such as starters, speedometers, etc., are certain to find a good market in the dual monarchy after the war.

Must Begin Operations at Once

In every case where exporting is tried, the work can best be done by native Americans—except if an applicant for the position possesses unusually good connections in the country—who can speak the language fluently and who are possessed of some psychological instinct and natural tact. This point, however commonplace it may sound, is extremely important and can perhaps be fully appreciated only by those Americans who have spent the last 2½ years in Central Europe, during which time relations across the Atlantic became strained more than once. At the present time the feeling toward America is rather friendly, and, unless the situation is changed radically, will continue to be so to the end of and after the war.

At any rate, preparations for handling the Austro-Hungarian after-war business cannot be made too early. Not only because doing business in this country of many tongues and nations requires deft treatment, but also because Germany is certain to recover with great speed from the war. The German Empire, due to the preparations made for the days of peace even now, when supreme efforts are still being made for waging the war, will beyond a doubt be the first country of Europe to get over the effects of the war, and will do everything in its power to obtain a maximum share of the world's trade, and logically will begin with the places nearest home: Austria-Hungary, Scandinavia, Poland, Italy and the Near East. The export to all these territories, is therefore, really one great question, and will have to be handled as such. Unless American manufacturers realize this in time, they will lose the greatest chance of the after-war period; just as—according to many economists here—they have done themselves out of a good share of lasting international trade by devoting their energies chiefly to the destructive and very temporary business of supplying the European war.

Jordan Limousine, Luxury Sedan and Custom Style Coupé



Above is the new Jordan seven-passenger limousine which sells for $3,000 f.o.b. factory. It is mounted on the standard four-cylinder chassis with 127-in. wheelbase. There will be only twenty-five limousines provided. In the middle is the Luxury sedan which has a permanent top but is convertible so that it may be used open or closed for different seasons. It lists at $2,350 f.o.b. At the bottom is the four-passenger coupé which sells for $2,300

COMBINING selected materials with workmanship of a high standard, the closed line of the Jordan Motor Car Co., Cleveland, comprises a seven-passenger limousine, a seven-passenger sedan and a four-passenger coupé. All are of low design, in accordance with the latest dictates of body construction, and the spring suspension is adapted to each to meet all load and road conditions and are rigidly mounted on the chassis to eliminate all rattles and squeaks.

Only twenty-five limousines will be provided, insuring distinction to the purchasers. The color is an unusually attractive blue or green, upholstery in the rear compartment being French tapestry with the front seats in long-grained, hand-buffed leather. There are window lifts, silk curtains, auxiliary seats folding out of sight, dome, running-board and reading lights, etc., besides many small bits of equipment, such as a watch and dictagraph phone. The price is $3,000, f.o.b.

As in the limousine, comfort is a great feature of the Luxury sedan. This body is of the convertible, permanent-top style, with windows folding into the doors. A car heater is provided, and the equipment is complete to the smallest detail. The sedan lists at $2,350, f.o.b. factory.

The coupés will be limited in output and will be of the same general finish as the sedan, the seating arrangement, however, being staggered, two passengers sitting at the right about 16 in. to the rear of the driver. The rear compartment will hold two suitcases and a traveling bag. The coupé sells for $2,300.

All three bodies are mounted on the standard Jordan sixty chassis with 127-in. wheelbase.

Suggests a New Testing Method

Novel Way of Plotting Engine Characteristics Outlined in Paper Presented Before Mid-West Section S.A.E.

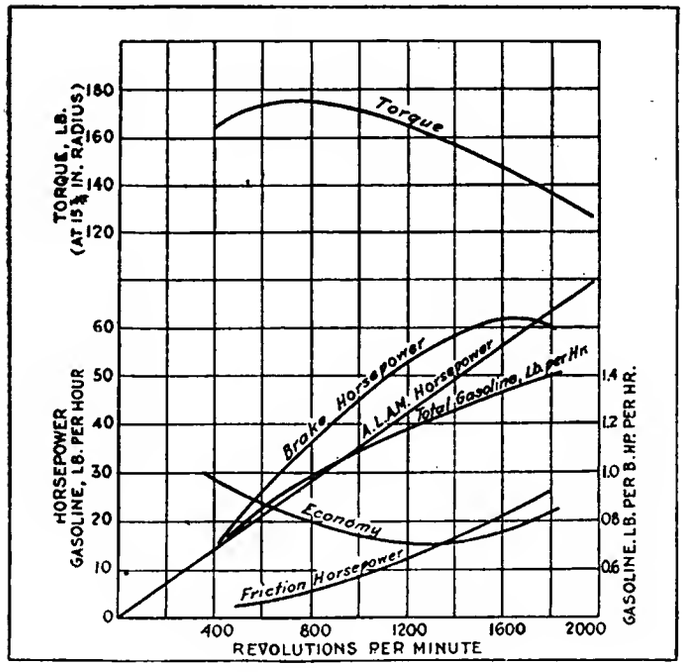
By Daniel Roesch

THE present method of testing variable-speed gas engines, as used in automobiles, motorcycles, marine craft or air craft, consists primarily of determining the *maximum* torque and horsepower at a number of different speeds. These results are plotted on co-ordinate paper; a smooth curve drawn through them represents the ultimate torque and horsepower characteristics for all speeds within the test range. The gasoline consumption is often taken simultaneously with these data. The gasoline consumption per hour or per brake horsepower per hour can then be plotted in the same way. These data are customarily taken under wide-open throttle conditions, the results being plotted with revolutions per minute as abscissas and the other variables as ordinates. These data and others less frequently taken during tests or derived from test results are:

1—Revolutions per minute of the engine.
2—Developed torque—average turning-moment developed.
3—Brake horsepower—calculated from 1 and 2.
4—Friction torque.
5—Friction horsepower.
6—Gasoline rate—preferably weight per unit of time.
7—Gasoline economy—weight per unit of power per unit of time, calculated from 6 and 3.
8—Jacket-water rate—preferably weight per unit of time.
9—Sensible heat in exhaust—by calorimeter.
10—Exhaust analysis—for incomplete combustion.
11—Radiation—preferably obtained by difference.
12—Air rate—weight per unit of time.
13—Mixture ratio—calculated from 6 and 12.
14—Depression in inlet manifold—indicating carbureter resistance.
15—Pressure in exhaust manifold—indicating exhaust-pipe resistance.
16—Spark advance.
17—Mean effective pressure, net—from 2, or 1 and 3.
18—Mean effective pressure, actual—from indicator card; from 1, from 3 and 5, or from 2 and 4.
19—Mechanical efficiency—from 2 and 4, from 3 and 5, or from 17 and 18.
20—Compression pressure—by indicator test.
21—Heat balance—percentage of heat supplied appearing as:

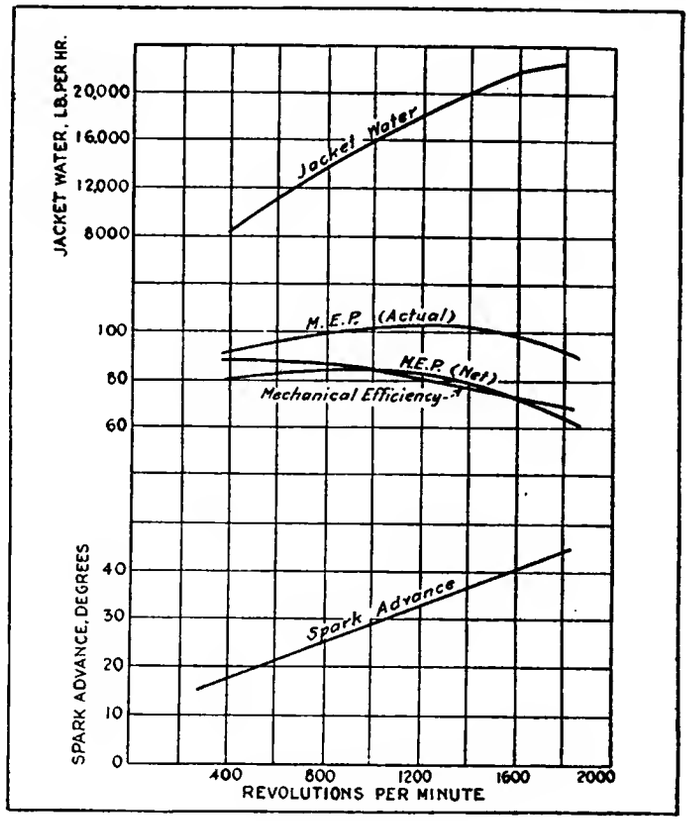
a Indicated horsepower.
  1. Brake horsepower.
  2. Friction horsepower.
b Jacket-water loss.
c Sensible heat of the exhaust.
d Incomplete combustion.
e Radiation.

These characteristics of a variable-speed engine show only its performance under wide-open throttle conditions—a condition often not maintained in use. It would follow then that an engine *A*, showing superior merits to an engine *B* under the usual test conditions, can have inferior



Above—Fig. 1—Torque, horsepower and fuel consumption curves

Right—Fig. 2—Curves for engine operating with wide open throttle



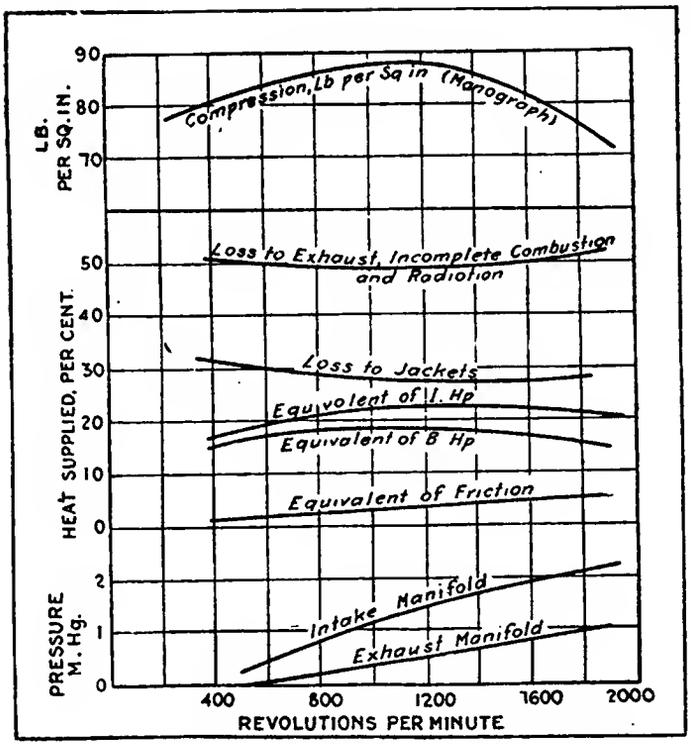


Fig. 3—Curves showing distribution of heat supplied to engine

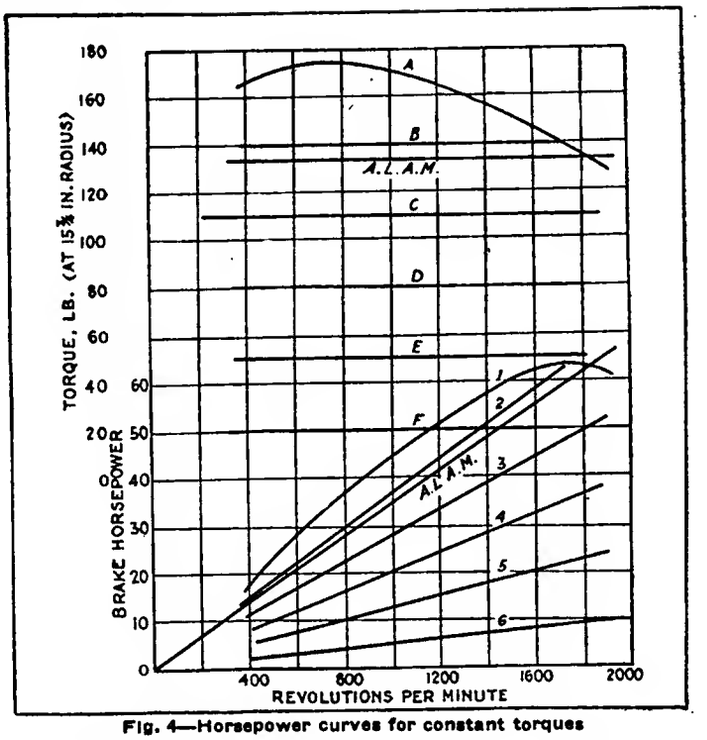

Fig. 4—Horsepower curves for constant torques

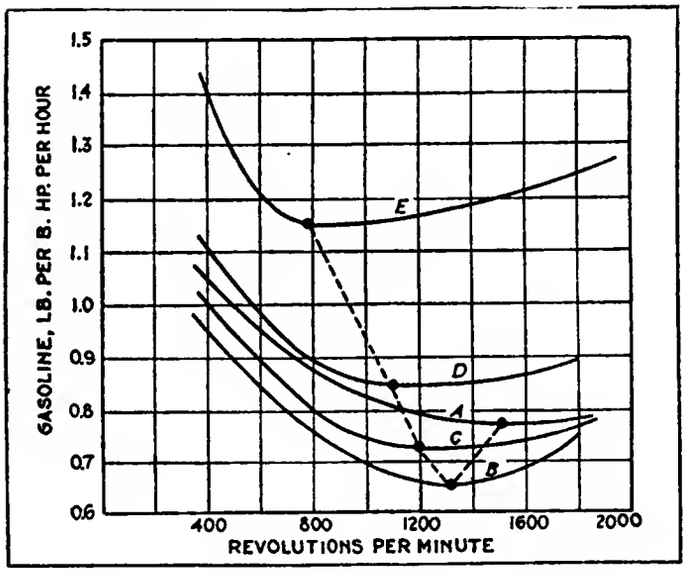

Fig. 6—Fuel consumption per brake hp. for constant torques

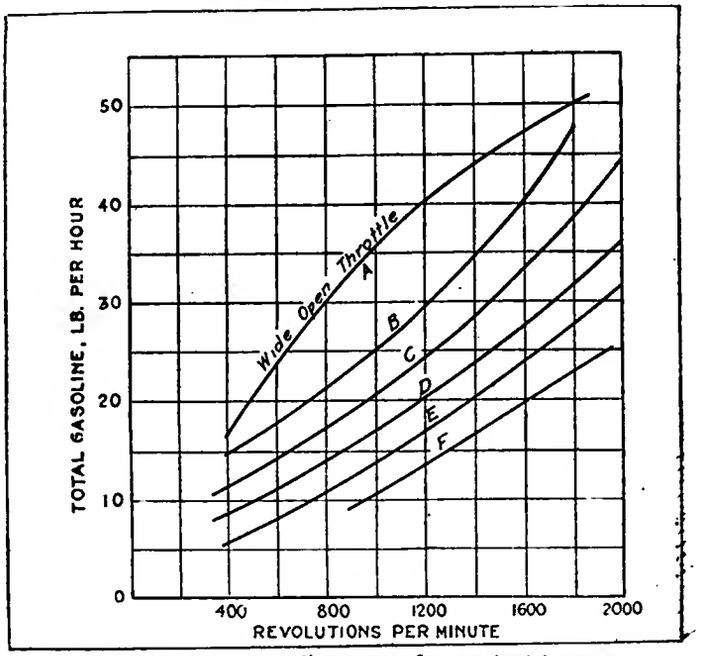

Fig. 5—Total fuel consumption curves for constant torques

merits when tested under partly-open throttle. This difference would have little moment where the engine operates largely at wide-open throttle, but might have a determining influence where the operation was chiefly at partly-open throttle, as in the automobile or motorcycle engine.

Preliminary Investigations

In order to investigate this question and develop a method of analysis for engines of this type the author suggested to Messrs. Cooban, Palmer and Stepanek, class of 1915, Armour Institute of Technology, that they conduct a preliminary investigation of this problem as a thesis. This investigation furnished the necessary data upon which the method was developed. Additional investigations utilizing and developing this method of testing are at present being conducted in the Armour Institute laboratories by Messrs. Fritze, King and White, class of 1917.

Electric-dynamometer tests were conducted on a high-class 4 by 5½-in. six-cylinder L-head engine built about June, 1914. The data were taken so as to cover all ranges of speed and load on the engine, whereas the customary method covers all ranges of speed at maximum load only. The engine was new, was fitted with stock pistons and had no extra provisions for lubrication. It was deemed therefore advisable not to operate at high speed or heavy loads more than 10 min. without decreasing the load. A run confined to this time limit gave accurate readings of power and economy with possibly questionable readings of jacket losses.

Since this paper deals with the method of obtaining new test data and not the actual figures obtainable, slight inaccuracies are of no particular consequence. The test data as replotted nevertheless represent performance characteristics in a new and broader way than heretofore observed. While the 1915 preliminary thesis established that such a method gave the desired information, it was considered more cumbersome than the one here described.

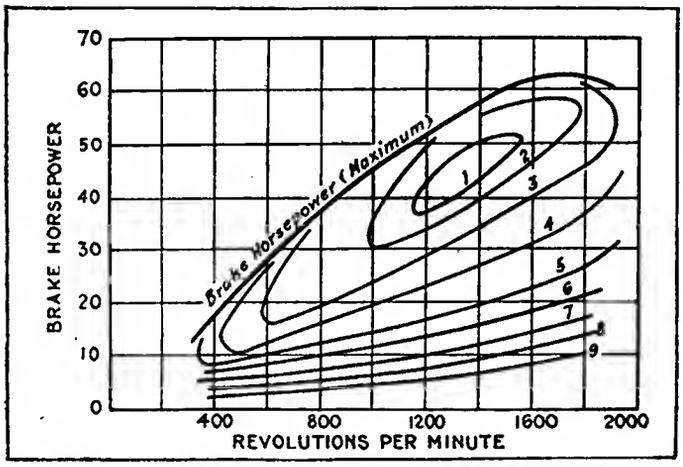

Fig 7—Lines of equal thermal efficiency

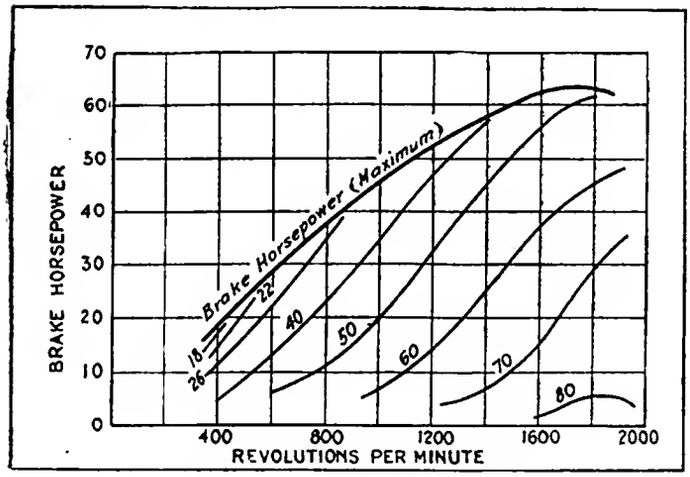

Fig. 8—Lines of equal spark advance

If data enumerated under items 1 to 21, inclusive, were taken during a test of an engine the resultant curves might be conventionally shown as in Figs. 1 to 3, inclusive. It is to be again noted, however, that only wide-open throttle conditions of operation are represented by these curves.

Methods of Complete Analysis

The complete analysis of an engine of the type considered can be determined from data taken in the following manner:

Tests are first made in the conventional way at various speeds with wide-open throttle. Whatever data are desired are then taken at each test speed and the customary characteristic curves plotted. One of these will be the torque curve, which is frequently taken as the pull in pounds at a 15¾-in. radius. This characteristic is represented by *A*, Fig. 4. The corresponding horsepower curve is represented by 1, Fig. 4, and shows the maximum power developed at any speed. If now a constant torque of, say, 140 lb. at 15¾-in. radius be maintained and the test conducted as before, we can obtain torque curve *B*, Fig. 4, and the corresponding horsepower curve 2. Similarly the curves *C*, *D*, *E* and *F*, and their respective horsepower curves 3, 4 5 and 6, are obtained for various constant values of torque.

Whenever the torque line is horizontal a constant mean effective-pressure, net, has been maintained by the engine; also the horsepower increases directly with the speed. This is similar to the N. A. A. M. horsepower rating and its corresponding mean effective-pressure, net. These lines are added to Fig. 4 for comparison. Since the horsepower of all but the first series of tests is proportional to the speed these curves will be straight lines and pass through the intersection of the axes.

Instead of selecting constant even-value torques for lines *B*, *C*, *D*, *E* and *F*, an alternative method would be to obtain these curves so that they would correspond to 67.3 lb. m.e.p., net, and, say, 15, 30, 45, 60, 75 and 90 lb. m.e.p., net. The advantage would be in subjecting various engines to like net mean effective pressures for each series of tests. This would facilitate comparison of performances. The disadvantage lies in having an odd value for the torque, which may be confusing during testing.

While this analysis can be applied to all of the data enumerated at the beginning of this paper, the factors of fuel consumption, mechanical efficiency and spark advance are probably the most important. The method of determining these and other characteristics under all conditions of load and speed will be indicated.

Obtaining Contour Lines

The total fuel-consumption curves for conditions as indicated, curves *A*, *B*, *C*, *D*, *E* and *F*, Fig. 4, are shown by curves similarly marked in Fig. 5. The gasoline consumption in pounds per brake horsepower per hour for each load condition was also computed and plotted in Fig. 6. These curves then furnish the necessary data to establish the load and speed for any particular gasoline consumption. A set of interpolation curves was then constructed for 400, 600, 800, 1000, 1200, 1400, 1600 and 1800 r.p.m. with brake horsepower as abscissas and gasoline consumption in pounds per brake horsepower per hour as ordinates. The data for these curves were taken from the curves in Fig. 6. These interpolation curves furnished sufficient points for, say, 0.7 lb. per brake horsepower per hour, to locate properly this contour line in Fig. 7. The other lines of equal thermal efficiency were plotted in a similar manner from the same in-

Line No.	1	2	3	4	5	6	7	8	9
Gasoline, lb. per B. Hp. per hour	0.66	0.7	0.8	0.9	1.0	1.25	1.5	2.0	2.5
Thermal efficiency on B. Hp.....	19.3	18.2	15.9	14.1	12.7	10.2	8.5	6.4	5.1

terpolation curves. Lines of equal gasoline consumption were thus established from these test data, as shown in Fig. 7. Lines of equal spark advance, Fig. 8, have been determined in a similar manner. Lines of equal mechanical efficiency, Fig. 9, have been determined by the conventional electric dynamometer method. There appears to be no reason why any of the other test data ever taken could not be graphically shown in a similar manner.

Summary

The chief advantage of the data presented graphically in the manner indicated is that they show concisely and clearly the performance of the engine under every possible condition of load and speed. Academically the method has already been found valuable in disclosing completely the various engine characteristics. Commercially the determination of cer-

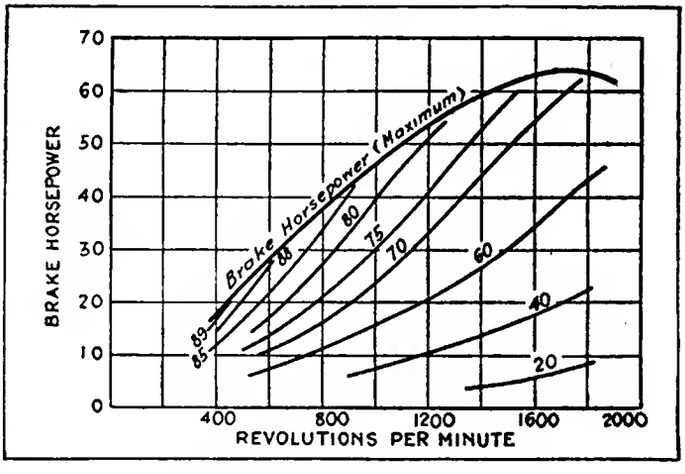

Fig. 9—Lines of equal mechanical efficiency

tain of the contour lines has been found valuable in design study of the engine features affecting them.

The gasoline-economy contour curves of various carbureters on the same engine should be of particular value for purposes of comparison. The same curves from different engines would be of value in more closely predicting car mileage per unit of fuel consumption.

The data on sensible heat in the exhaust should be of value in the design of kerosene carbureting devices, with which considerable heat is required for fuel and air preheating.

The jacket-water rate and loss should be of value in pump and radiator design.

The spark-advance contour curves are valuable in design of automatic spark-advance mechanisms, which advance correctly the spark for load and speed variations.

May Develop Other Methods

No doubt many other applications of test data recorded as indicated will become apparent upon study by the automobile-design specialist. It is hoped that the presentation of this paper will develop discussion showing: 1, The weak spots in the method and means of remedying them; 2, benefits to be derived from data thus presented; and, 3, other methods for ascertaining similar results.

Studebaker Dealers and Sub-Dealers in South America Meet in Buenos Aires

BUENOS AIRES, ARGENTINA, Nov. 4—The annual meeting of Studebaker dealers and sub-dealers in South America was instituted in this city during the past fall, when D. B. Richardson, manager of the Studebaker interests in South America entertained all of the dealers and sub-dealers at a banquet as well as a trip through the city park system.

The meeting of dealers in a conference of this kind is unusual in Argentina. The city of Buenos Aires has not its association of automobile dealers as have the cities in North America. Here there has never been any getting together of dealers handling rival makes of cars. Since the war it would be practically impossible to get around the same banquet table dealers representing English, German, French and Italian cars. It is this fact that Buenos Aires dealers handle cars made by rival countries that has held back cooperation of Buenos Aires dealers. Unquestionably this movement by the Studebaker organization will have its influence, and manager Richardson has made up his mind to have started in this city an organization of automobile dealers such as exists in so many cities in the United States.

The illustration shows a typical Buenos Aires scene with the parade of Studebaker cars filling the street. It is a park drive in the Palermo Park, which is one of the show points of Buenos Aires.

The rapid increase in the number of U. S. A. cars exported to Argentina is an indication of the development which may be expected in the automobile business in this country.

Care of Batteries on Stored Cars

75% of Battery Troubles Are Due to Neglect of Dealers To See That Cars Are Turned Over to Buyers with Battery Fully Charged

EDITOR'S NOTE:—From a paper presented by H. S. Bentley, of the Willard Storage Battery Co. before the Indiana Automobile Service Managers' Assn. Dec. 9

BECAUSE of the failure of motor car dealers to give the storage battery a proper chance for its life, by neglecting to turn it over to a customer with a full charge, at least 75 per cent of all future storage battery troubles and dissatisfaction are born. If he knows the battery is half or more discharged, he quiets his conscience by thinking that the generator will build it up to a condition of full charge. This may happen in a few cases, but in most cases the current produced by the generator will not be sufficient to any more than replace the current used for everyday lighting and cranking. Consequently, the battery continues in a more or less starved condition for several weeks or months, and ultimately goes dead. Reforming may restore it to serviceable condition, or new insulation may be necessary. In either case the owner expresses dissatisfaction with the battery, which dissatisfaction, if properly placed, should be directed toward the dealer who neglected to furnish a new car with a battery in proper condition for service.

Half-Starved Batteries Cause Trouble

Battery trouble develops in other directions from half starved batteries on new cars. If the battery and car have been in transit or in stock for a considerable period, the discharged condition of the plates may make them so hard that great resistance to the charging current is set up and the plates are severely overheated on the first long run on a warm day. The normal generator output which would not injuriously affect a healthy battery will produce this result in a neglected and discharged battery.

We have already shown that it is always of very great importance to the life and service obtained from a battery, that the dealer should have it charged upon receipt, if necessary, and thereafter keep it in a fully charged or nearly fully charged condition until the car is sold. Naturally, this is of much greater importance with respect to batteries received on stock cars to be held during winter months. This is true, because the storage period is ordinarily much longer than the period during which any cars are kept in stock during the selling season.

We come then to the question of the means which a dealer should take to preserve these batteries from deterioration, so far as possible.

Ship Dry Batteries for Winter Stock

First of all, manufacturers should arrange with their dealers to ship them "export" or "dry" batteries with all cars to be stocked during the winter season. These batteries are prepared without electrolyte, and if kept in a moderate temperature of from 35 to 60 degrees will need no further attention, and will not suffer deterioration to any degree until they are needed for service. A few days before they are to be used for service they must be filled with electrolyte of the proper strength and given a reforming charge until gravity and cadmium tests show that the plates are in a fully charged condition.

Must Take Precautions

Manufacturers who ship batteries for winter storage in the dry condition should take the precaution to paste a seal over the filling aperture of the gasoline tank, calling attention to the fact that the battery on the car is without electrolyte, and must be properly filled and charged before the car is used. If this precaution is not taken, it would be possible, through carelessness, for batteries to be charged while dry, and consequently ruined. If batteries are received in the regular way with electrolyte, they should be fully charged upon receipt, and given sufficient charging every 2 weeks thereafter to keep them in a fully charged condition. Due to the chemical action, there will be more deterioration during the storage period than would be the case if they were prepared and stored in the dry or export condition.

Shipping Cars Without Batteries

It has been proposed as a possibility that manufacturers ship cars for winter storage without batteries, and some provision be made for supply batteries in proper condition for service when the cars are sold in the spring. It is manifestly impossible for a storage battery manufacturer to undertake to make deliveries on manufacturers' orders through their retail selling organization. The difficulties of making proper shipment to proper points, and of handling the billing and other details would make such a plan prohibitive.

Value of Service Stations

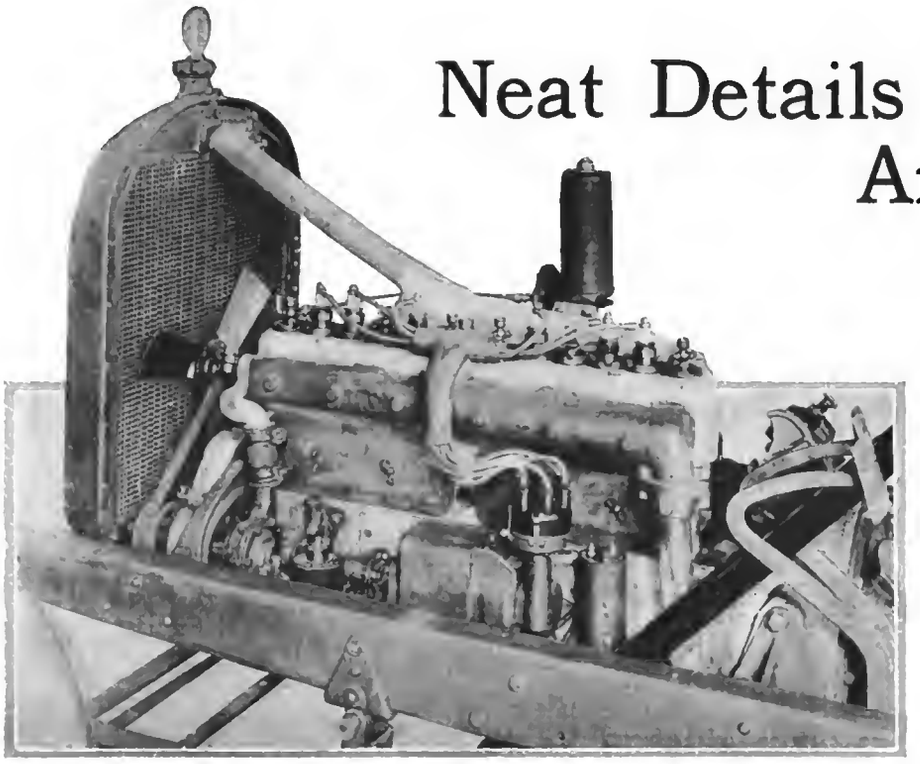
It must be recognized, however, that the dealer seldom has the equipment or skilled employees necessary either to prepare dry batteries for service, or to properly care for wet batteries economically. Careless or inexpert garage employees already have to their discredit the absolute ruin of hundreds of batteries, either through overcharging or charging in reverse. So far as the Willard company and Willard batteries are concerned, competent battery service stations have been provided at over 800 points in the United States and Canada, in whose hands either wet or dry batteries may be placed for storage and preparation with absolute confidence. Dealers may, therefore, unload on the Willard service organization all worries and cares in connection with batteries received with winter stock cars. The cost of this service will be reasonable in every case, but will necessarily be governed to some extent by local conditions in the various territories. For example, a service station at Buffalo may pay only 1½ cents per kw. for electric current, 4 cents per lb. for electrolyte, and 30 cents per hr. for labor. At Butte, Montana, electric current may cost 12 cents per kw., electrolyte 10 cents per lb., and union labor may be at the rate of 75 cents per hr.

Make Dealers Responsible

Considering the conditions as outlined, we believe that the best interests of the motor car manufacturer, storage battery manufacturer, motor car dealer, and ultimate car owner, demand that every motor car manufacturer put up to his dealers their responsibility for the condition of these batteries and recommend in the strongest possible way that the dealer place all such batteries as soon as received in the hands of the local service station of the storage battery manufacturer.

Neat Details Features of American Six

New Design by Louis Chevrolet—Full of Character — Lubrication by Unusual System



Mounting of Carter tank and Gray and Davis starting motor on American Six engine. Note the bracket on the bell housing carrying the accelerator pedal and starter switch

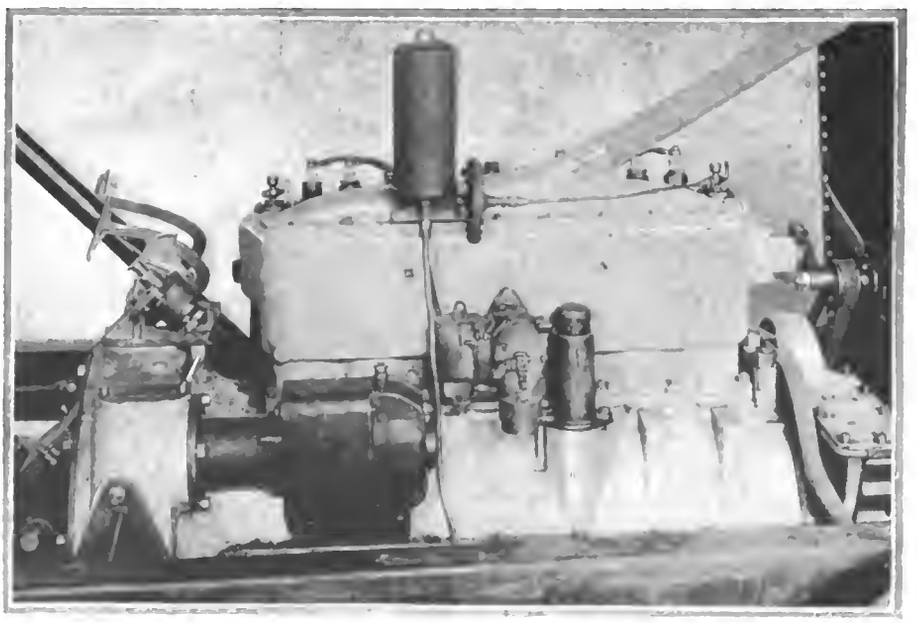
THE American Six, made by the American Motors Corp., Plainfield, N. J., while in no respect unconventional in a general way has many points which make it a distinctive car. With the exception of engine and frame it is assembled from well known units, but the detail has been worked out with great care, the engineer's particular aim being to produce a car which will have no petty weakness. After completing the design and preparing for manufacture the price has been set at $1,285 with five-passenger body, this being a little more than the original idea but necessary to maintain the standard of quality.

An almost unique feature of the American Six is that the chassis is complete in itself and is drivable without the body, all wiring and everything except the actual instrument panel being a chassis attachment. In the illustrations it can be seen that there is a light steel frame bolted to the top of the bell housing. This holds the accelerator pedal and the starting switch and also has a clip incorporated which takes the unit assembly of all the wires that have to go to the cowlboard. All the instruments are mounted on a plate that sets in the center of the cowlboard, so that there is only the atachment of this to be performed after the body is put on the chassis. On a chain assembly line this is an immense advantage, for it means that there are no awkward, half concealed things to get at. In connection with the panel assembly for the instruments there is a novelty which should appeal to the owner, this being the location of the single main fuse directly beneath the panel light and on the front of the panel. This makes the replacement of a blown fuse ideally simple and also allows the fuse to be used as a plug switch; since removing it prevents flow of current in any circuit.

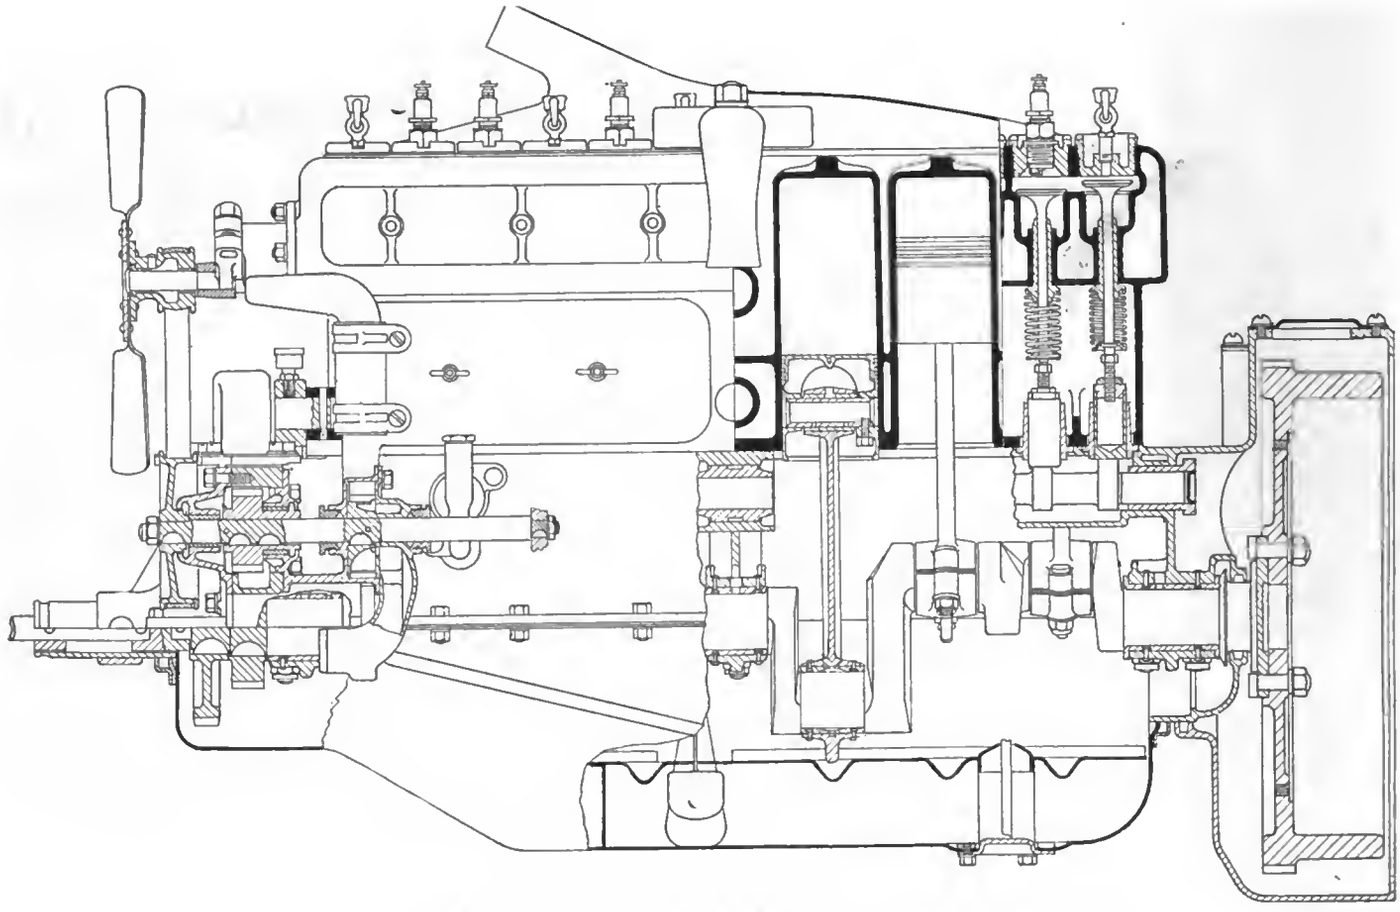
Engine Is Own Design

The 3 by 5-in. six-cylinder engine is not a stock article, but is made specially in a plant associated with the American Motors Co. Broadly it is of conventional design, but it has several points of novelty. The cylinders are an L-head block without a detachable head, the crankcase being aluminum throughout. To obtain quietness the camshaft lubrication has been studied and the shaft is inclosed in a tunnel to which oil is fed by a gear pump. This keeps the tunnel so nearly full that the tappets dip in the oil and the cams are entirely submerged. From this tunnel the overflow fills dip troughs beneath the connecting-rods and the oil splashed thence collects in deep gutters cast on the webs of the crankcase that conduct the lubricant to the three main bearings.

In the sectional view of the engine a neat point that should be noticed is the attachment of the water pump. As this delivers to the front end of the cylinders the outlet pipe has been ingeniously combined with the fan support, making a slight saving in weight by the combined functions. The at-



Generator and ignition unit with coil alongside mounted so as not to interfere with valve accessibility



Section of American Six engine. Observe ample water spaces round valves and cylinders

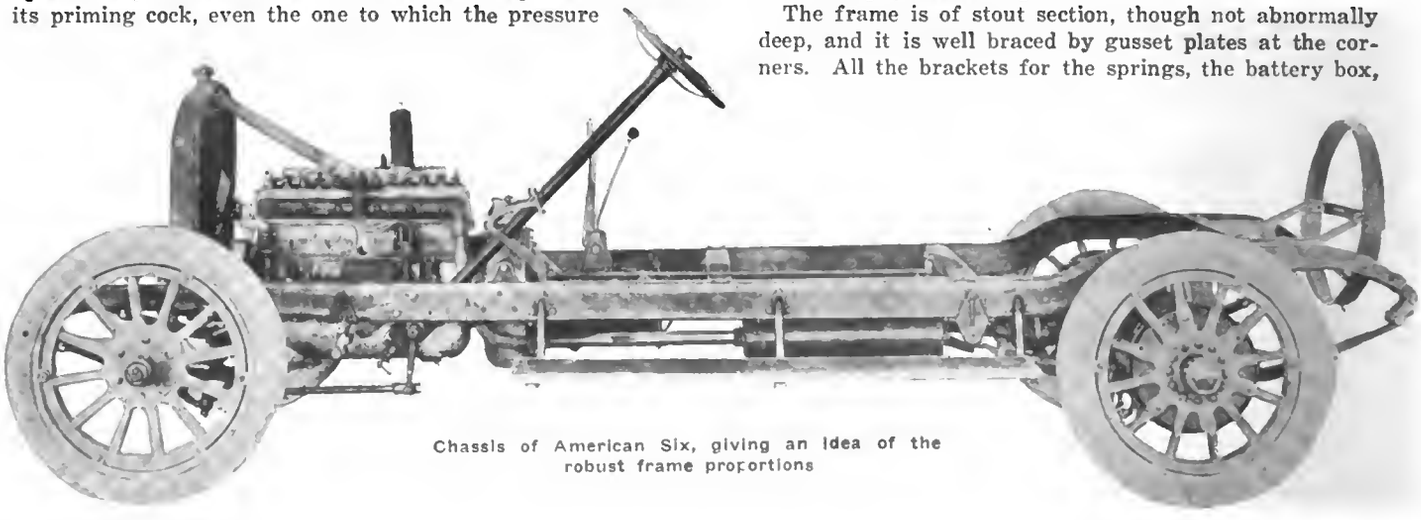
tachment of the pump to the crankcase so as to insure alignment can also be seen in the drawing.

Light cast iron pistons are used and the crankshaft is 1¾ in. diameter with webs big enough to reduce the tendency to distortion to vanishing point at all usual speeds. Care is to be observed in the layout of the electrical accessories, which are all of Gray & Davis manufacture. With the generator the closed circuit ignition distributer is combined, and the coil is mounted alongside the generator on the same crankcase platform. The starting motor is on the upper side of the crankcase, where it is out of reach of the worst of mud and water, and both generator and motor are perfectly accessible. In all, the tappets, electrical units and the pump gland are just about as accessible as they well could be, while the Zenith carbureter bolting directly to the cylinders is high up and easy to reach. Each exhaust valve cap bears its priming cock, even the one to which the pressure line for the Carter fuel feed is attached, and the Carter tank is clipped to the cylinders where it requires the minimum length of pressure piping.

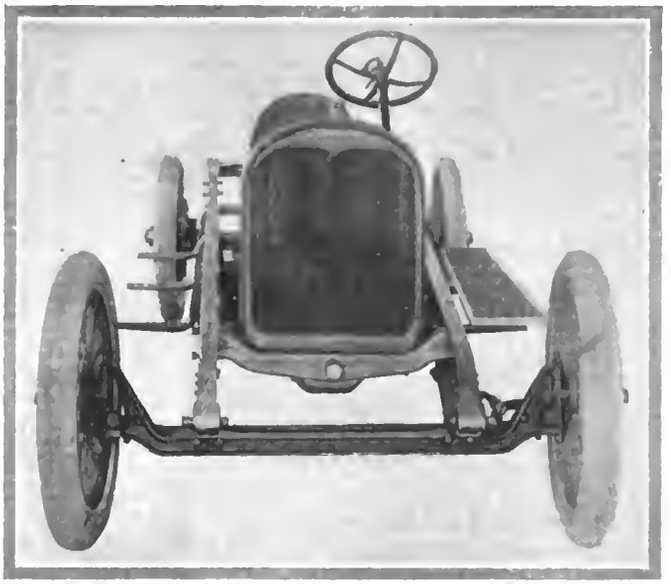
Strong, Simple Frame.

A three-speed Mechanics Machine Co. transmission is attached by a bell housing to the engine, and the clutch used is a Borg and Beck dry disk. In the housing are the necessary cover plates for giving access to the clutch adjustment. These are made more than usually easy to get at because the toe board has nothing fixed in it, the bracket mounting for the starting switch and accelerator allowing the toe board to come away without trouble. The clutch has a very light pedal action and the gear lever is set in a convenient position, so that gear shifting is easy even for a woman possessed of little physical strength.

The frame is of stout section, though not abnormally deep, and it is well braced by gusset plates at the corners. All the brackets for the springs, the battery box,



Chassis of American Six, giving an idea of the robust frame proportions



Distinctive radiator of American Six. A mudguard extension is fitted beneath the radiator, though not shown here

Above — Instrument board with unit assembly of all switches and gages in a central panel

Right—Lamp bracket and fender support, showing method of wiring for headlamps

etc., are massive, the idea being to provide a frame which will retain its original rigidity. The springs are all semi-elliptic, the rear ones being underslung, and Hotchkiss drive is employed.

Salisbury Rear Axle Used

A Salisbury rear axle is used with a gear ratio of 4 5/12 to 1, and the brake equalizers are mounted directly upon the axle housing. This allows a single rod to be run from the hand lever to the axle, and the pedal has one rod going to a short lever attached to a pivot on the middle cross member of the frame, a second rod going from the same lever to the rear axle equalizer bar. The intermediate lever brings the center of oscillation of the brake system near to that of the axle due to the Hotchkiss drive. The wheelbase is 122 in., and the tires 32 by 4 in.

Lavigne Steering Gear

For the steering gear a Lavigne has been chosen, this being a type with an easy action and provision for adjustment to take up slack. The front axle, which is a conventional forging, is set with a 5-deg. rake so as to provide a caster action, giving just enough natural return to the straight position of the wheels after making a turn to provide a "feel".

Only a five-passenger body will be made, at least at first, and the long wheelbase allows this to have plenty of room especially in front, the driver's compartment being well above the average standard of comfort. A narrow center cowl is used, this having polished wood at the back giving a nice finish to the tonneau. Leather upholstery is included and the color is a dark blue. In attaching the fenders rigidity is the feature most sought and the lamp brackets are utilized to assist this. A matter of detail is again apparent here, for the wires to the headlamps are taken up inside the mudguard, of course inclosed metallically, and led through beside the bracket, this reducing the length of the wire which is exposed to a minimum.

Olympian Car To Replace Pontiac Chassis

Olympian clover-leaf model mounted on the standard four-cylinder chassis to be manufactured by the Olympian Motors Co., Pontiac, Mich. This concern recently took over the Pontiac chassis. The new cars are going through production and test models are on the road

THE Olympian Motors Co., Pontiac, Mich., which recently took over the Pontiac chassis, will discontinue the manufacture of the latter after existing contracts have been filled. The new car which the Olympian company is manufacturing will soon be going through regular production and the trial cars are now on the road.

The chassis is very much the same as the Pontiac chassis except that it is 2 in. longer in wheelbase. The body is an original design and the complete car will be shown at the Sherman House in Chicago during show week. The car has a Golden, Belknap & Swartz unit power-plant with block 3¾ by 4¼-in. engine. Starting and lighting are by the Auto-Lite system.

Car Builders Can Co-operate with Electric Device Makers

Increasing Demands on Generator Make More Room in Mounting Necessary—Best Speed Ratio Should Be Determined—Co-operation on Battery Ignition Possible—Engineering Facilities Little Used

EDITOR'S NOTE—*From a paper presented by J. B. Replogle, director of research of the Remy Electric Co. before the Cleveland section of the S. A. E. on Friday, Dec.* 15.

THERE was a time in the history of the automobile art when the entire electrical equipment of a car consisted of a magneto to ignite the fuel in the cylinders and a pocket flash lamp to observe the fuel in the tank. As a conventional magneto gives two impulses per revolution, it was found necessary to drive the magneto shaft at engine speed, if the engine was a four-cylinder one, and at one and a half times engine speed if the engine had six cylinders.

Later it was observed that it was exceedingly difficult and inconvenient to light a lamp with a match in the rain and wind and that it was a laborious and sometimes dangerous task to crank a motor, so electric lights and cranking motors were installed, the source of the electric energy for these being a storage battery and a generator to keep the storage battery charged.

Later still, when it was learned how easy it is to transform electricity from one form to another, many men came to the conclusion that one generator of electricity on a car is sufficient, and in such cases, battery ignition displaced the magneto, and the generator was driven from the shaft that formerly drove the magneto and at one time it was an almost universal practice to drive generators on four-cylinder engines at engine speed and on six-cylinder engines at one and a half times engine speed. Of cars that we have listed, nearly 65 per cent are designed with the generator running either at engine speed or one and one-half times that speed. In many cases, no doubt, this is a very good ratio, particularly the one and one-half ratio, but it seems to indicate to me that the automobile designer has not given very much thought to the question of what is the best ratio.

Determining Best Speed Ratio

So the first way in which the automobile manufacturer can co-operate with the electrical accessories manufacturer is a careful consideration of the best speed ratio of generator to engine. The best speed ratio is a matter of gearing. It is the highest ratio that will permit of quiet gear operation and sufficient clearance space for the generator.

A very much larger proportion of the operation of machines is below 15 m.p.h. than formerly. This is largely due to the congestion of the streets and roadways. Touring around our large cities on a clear Sunday or other holiday has almost evolved into a slow parade. The cement and brick roadways are rather narrow and do not permit safe driving with more than two machines abreast and, as the parade is a double one, passing in both directions, it is usually quite hazardous to attempt to pass the machine in front. As a consequence, each line of the parade moves at a speed controlled by the wish of its most leisurely driver. Not only from this cause, but also from the number of children, motor trucks and day-dreaming pedestrians on the streets, a very large percentage of machines are being driven at low speeds a large proportion of the time. Notwithstanding this, the driver feels he has a real grievance if his battery is not kept charged.

It is a fact well known to electrical designers, and also to engine designers, that size can be traded for speed, and there is no doubt that generators can be and often are made large enough to supply the necessary charge to the battery even under these adverse conditions, but that adds weight and expense and is undesirable.

Should Avoid Causing Noise

But in the attempt to secure a high ratio, there are several limiting features of gear design that must not be overlooked. In the desire to run the generator at a high speed relative to the engine, many designers have made the mistake of having the gearing so designed that there are insufficient teeth in the pinion on the generator shaft to permit smooth and noiseless operation and a disagreeable howl has resulted at speeds where the generator is carrying its maximum load.

I cannot emphasize too strongly here the need of first-class gear making when high generator ratios are used as the presence of the teeth in the generator armature causes the load on the gears to vary harmonically and an unpleasantly loud sound will result unless the gears fit and mesh nicely.

A further difficulty occasionally met with in designing for high ratios is that the generator drive pinion is of such small diameter that insufficient clearance between generator shaft and crank case results and a more or less freaky type of machine must be designed to fit in.

While the application of electrical apparatus to automobiles is comparatively new, it must not be overlooked that the electrical art of itself is relatively mature and standardization has been carried much further than in the automobile art. During the period of its evolution very many forms of generators were developed, tried out and abandoned until to all intents and purposes but one form remains, namely the round or cylindrical type. You are using generators and motors in large quantities in your several plants and you will find that almost without exception they approximate the cylindrical form. This accumulated experience of an older art, when applied with common sense and judgment is of more value than any possible amount of theorizing on the subject, and the round type generator stands to-day the result of all the electrical brains that have made up electrical history. Therefore when you are designing your engine you can co-operate with the electrical accessories manufacturer by keeping in mind the desirability of applying standard generator frames and by adopting as high a generator gear ratio as you can without sacrificing smooth, quiet operation or necessitating the adoption of other than standard forms of machines. I might note here that to date, this highest gear ratio has not usually exceeded two to one.

Space for the Generator

That brings us naturally to the second item where the automobile manufacturer can co-operate, namely in designing so as to permit comfortable space for the generator. This statement will immediately provoke a reply that there is not

comfortable space in an automobile for anything except the passengers—but, notwithstanding this fact, I hope to show you where it will be to your advantage to allot a larger space for the generator.

As noted previously, the use of electricity was limited at first to igniting the charge in the cylinders. Next it was used for lighting the roadway and the tail lights. Then to illuminate the instruments on the cowlboard. In a limousine it is used to show forth the splendor of milady on her procession to the opera. It is used to crank the motor and blow the horn. It is used further to warm your fingers in the steering wheel. To heat the rechristened kerosene in the carbureter. To shift the gears and to play a fan on our overheated countenances. It can be used to apply the brakes and inflate the tires. In addition to all of this, the market offers quite a number of devices that purport to permit operation of the headlights at full brilliancy without conflict with the authorities or danger to other people and that takes more electricity.

Then we have the ubiquitous dirigible searchlight which also takes more electricity and all of this must be supplied by the generator. The first thing you know you will be overwhelmed with complaints that the electrical systems are not working right; the lights are dim; the starting motor will not crank the engine as it should; the batteries will sulphate and a host of other troubles will follow because you are using electricity faster than you are generating it. The space you allotted for the generator was sufficient when it only had to supply current for the starting motor during the summer months when the engine is not stiff and when the lights were few in number and operated but a short time in the later summer evenings. But with all of the accessories we now have demanding their share of current and with cars operated the year around and standing for hours at the curb with the lights burning during the long winter evenings, to satisfy the police authorities (although in a brilliantly illuminated space where you cannot avoid seeing them without shutting your eyes), then cranking a cold, stiff motor, the space allotted for the generator is insufficient. Several companies have developed a profitable business supplying extra equipment to garages for recharging batteries because the generators on the cars have insufficient capacity. In my estimation the time has come when you must be more liberal with the space allotted for generator and must demand and be willing to pay for a larger generator for the car or you will soon be swamped with complaints. That is the second item where you can co-operate with the electrical accessories manufacturer.

Difference Between Seasonal Demands

It might be advisable, before abandoning this phase of the subject, to note that the extreme difference between the electrical demand in mid-summer and in mid-winter has presented quite a problem to the electrical accessories manufacturer, owing to the peculiarities of a storage battery. In hot weather a storage battery of given rating can only receive a limited amount of current input without distress, due to rapid evaporation of the electrolyte and heating and buckling of the plates, and shedding of active material therefrom. But providentially, the electrical demand adapts itself to temperature conditions in such a way as to co-ordinate with the limitations of the battery, provided the generator output is made to co-ordinate with the electrical demand. That is to say, a battery cannot stand a large charge rate in warm weather for a long period, but it does not need a large charge rate in warm weather because the demand in warm weather is relatively low. But in cold weather the battery can stand for a much greater charge rate, the demand is much greater, and therefore the generator can and should be designed to give a greater average charge rate in cold weather than in warm. Heretofore this has been accomplished occasionally by hand-operated adjustment of the generator, but the company with which I am associated has evolved and is now commercially producing generators which automatically accomplish this by means of thermostatic control.

Need Substantial Starting Motor

There is opportunity for co-operation with regard to the starting motor also, although the situation there is not so acute as with the generator. The principal items are to have a very low resistance connection between the battery and the starting motor and to be willing to pay for a good husky motor. Let us consider each of these items briefly. Under the most favorable circumstances only about half of the energy used in breaking away a stiff engine ever gets to the starting motor. The remainder is lost in the battery, leads, connections and switches. Therefore, it is very important that you keep these low, either by placing the battery close to the motor or by using large cable to make the connections. Also to be sure that the kind of switches you use and the connections you apply are of high conductivity.

As regards the size of starting motor, here again the widespread use of cars throughout the winter has altered the situation markedly. The factor of safety of starting motors is just barely sufficient, in many cases, to take care of stiff, newly adjusted engines which have stood all night in a cold garage, and I believe a small additional amount spent for more power in the motor, and more ability to spin it when cold could well be withdrawn from selling expense because of the user's satisfaction in his equipment.

There are two kinds of strong motors, wastefully strong and efficiently strong. The torque of a motor is due to current, copper and steel. If you do not care how much current you use to crank the engine, you can economize on copper and steel, but if you want a thoroughly satisfactory equipment it must be an efficient one and that requires copper and steel and sufficient space in which to mount it.

Co-operation on Battery Ignition

In the consideration of co-operation of the automobile manufacturer with the electrical manufacturer in the matter of ignition, I will confine my comments to battery ignition, as that forms such a large proportion of ignition in this country. There are four prominent operating principles in battery ignition, namely, maximum speed at which ignition sparks will be supplied, minimum voltage at which ignition can be accomplshed, amount of current required at average driving speeds, and the energy contained in the spark for ignition. An ideal ignition system would be one that could fire an engine at 10,000 r.p.m. would operate perfectly with 1 volt, would require but a tenth of an ampere at 12 m.p.h. and would have so much heat in the spark you would not require any gasoline.

We cannot make such an ideal system, and you wouldn't buy it if we could because of prohibitive cost, but you sometimes ask for a system that comes unnecessarily near this ideal in some one characteristic and I am going to try and show you how you cannot eat your ignition cake and have it, too. To do this, I shall be compelled to discuss some elementary ignition principles and, if I repeat some things you already know, you will please bear with me, as I may hereby bring out a mite of information that is new to you.

A spark ignites the compressed charge because of its heat. This heat results from the dissipation of energy. This energy we get from breaking down the magnetism in a bundle of iron surrounded by two coils of wire. We build up the magnetism by sending electrical energy into the coarse primary winding and we carry a part of the energy to the spark by means of the secondary winding when we break down the magnetism. Now the electrical energy we send into the primary winding is in two parts. One part merely heats the coil and is wasted. The other part is stored in the coil in

the form of magnetic kinetic energy and this is the part we use to ignite our charge. The volume of this useful part depends upon two things, the current we send into the primary and the inductance which is a peculiar property of every electro-magnetic circuit. I am not going to take the time to try to show you what the inductance is, although it is probably the one most important characteristic of a coil, but I am merely going to tell you that this inductance has two effects that are of interest to us.

As noted before, it is absolutely essential that it be present to permit the storing of useful energy in the coil, and on the other hand, it tends to reduce the speed at which useful energy can be stored in the coil. So you see if we want a very high speed coil, we cannot have very much inductance. If we do not have much inductance, we must use a very large amount of current at running speeds or we will not have a desirably hot spark, and we cannot get sufficient current at very low voltages to produce an operating spark.

Speed and Power Requirements

If a customer asks us for a system that will fire his engine at 5000 r.p.m. we can easily give it to him, provided he does not object to using several amperes at running speeds and will guarantee his battery will never be below 4 volts. But if his engine will never run faster than 2000 r.p.m. he is buying something that is unnecessarily expensive for his needs, not necessarily more expensive in money, but in current consumption or satisfactory starting in cold weather with low battery. If your ultimate customer will never want to drive his machine so his engine is turning over at a greater speed than 2000 r.p.m. do not insist that we furnish you with ignition equipment that will show a bench test of 3500 r.p.m. because it will be necessary to sacrifice either current economy or heat of spark or low voltage operation to do so, one is practically as easy and inexpensive to make as the other, but you cannot have both without abrogation of the laws of nature.

So you can co-operate with the electrical accessories manufacturer by asking for what you need to use in the way of speed and not for what you want to show on a bench. Special equipment for stunt tests can be supplied without interfering with the efficiency of the general production.

Finally, you can co-operate with the electrical accessories manufacturer by making more use of his training and equipment. The accessories manufacturer is of the opinion that you cannot possibly know as much about the electrical equipment of an automobile as he, or are you nearly as well prepared to carry on experiments concerning the electrical equipment. He believes the time has come when it is decidedly expedient if not necessary for you to enter more freely into conference and discussion with him and to bring your electrical problems to him spontaneously so that he can render you real service in doing investigation and development work that he is best qualified to perform. He has complete and well organized laboratories and engineering staffs at your disposal that you are not making most efficient use of. He wants you to consider them your property, organized for the express purpose of giving you service at the time when it will do you the most good, namely in the period of design.

He is making an earnest effort to comprehend your problems and to formulate a solution for them. He has bought your cars and is driving them under all imaginable conditions in the endeavor to foresee future problems the solution of which will be of incalculable benefit to you. You and he are both trying to peer into the dim and misty obscurity of future trend of the art and he feels that if you and he travel together, he may often aid you in keeping to the road and occasionally your private road map may point out a way for him when no way is visible. Let us get together.

Reducing Waste Labor By Showing Results

WHEN a worker turns out a large percentage of defective parts in the course of his labor, he wastes time, effort and money, both for himself and his employer, besides endangering the quality of the product. To eliminate waste labor, reduce the loss of time and money, and to improve the quality of their product, S. F. Bowser & Co., Inc., Fort Wayne, Ind., have installed a plan of displaying damaged and spoiled parts in bins to their employees.

Factory meetings, which are held at indefinite periods but occur about once a month, witness the gathering of all shop employees. Addresses are made either by officials of the company or by outsiders on different subjects calculated to promote efficiency. In recent addresses, the bins filled with damaged parts are wheeled in before the men and lectures have been given calling attention to the methods of increasing production through intelligent, efficient work rather than by hurried, careless labor.

The company states, to its employees, that it is better business for them and consequently for the workers, to do a normal amount of work which results in perfect product rather than to produce a great quantity some of which must be scrapped because of defective workmanship.

The psychology of the sight of the damaged parts in connection with the address has been taken into account and the company believes that the plan will result in a better quantity of work and greater co-operation among the men. The idea is practically a new one and definite results regarding the merits of the plan cannot be stated at this time.

It is readily possible that further developments of the psychological principle embodied in the plan can be worked out to the mutual benefit of employer and employee. The various departments could be brought into a state of friendly rivalry as to which showed the best record as revealed by the size of the display of spoiled and damaged parts standing against it. Also the pride of the men in their work could be capitalized to the extent of rendering them ashamed of contributing through carelessness or poor workmanship to the pile of evidence arrayed against their respective departments. Other variations of the idea in accordance with the requirements of the plant to which it is applied could be devised.

Damaged parts on display at the plant of S. F. Bowser & Co., Inc., Fort Wayne, Ind.

Kent four-cylinder, five-passenger touring car selling for $985

Individuality in Kent Four

New Car Has 3¾ By 5-In. Engine and 116-In. Wheelbase — Standard Units Used Throughout Chassis—Body Lines Up to Date

INDIVIDUALITY of design, combined with the use of very high-grade units in the chassis, renders the four-cylinder Kent, produced by the Kent Motors Cerp., with factory at Bellleville, N. J., and offices in New York City, a very substantial and attractive car, especially when its price of $985 is considered.

Unusual Magneto Mounting

The compact unit power plant, which is illustrated herewith, employs a 3¾ by 5-in. Continental engine that is stated to develop 40 hp., an output which is amply sufficient for the car, the weight being given as about 2500 lb., fitted with either the five-passenger touring body or four-passenger club roadster design. A two-unit Bosch electrical system is used for starting and lighting, ignition being by Bosch magneto. An unusual feature in the mounting of the units is that the generator is driven directly from a gear meshing with the crankshaft and the magneto is placed toward the rear so that it takes its drive from the generator. This arrangement is well illustrated in the accompanying view of the exhaust side of the power plant mounted in the chassis. Carburetion is by a 1¼-in. Zenith instrument of a special type fitted with spray adjustment. Fuel feed is by the Stewart vacuum system from a 15-gal. tank suspended at the rear of the chassis.

A disk-type clutch situated in the flywheel transmits the drive from this clutch through a three-speed and reverse selective gearset. The gears employed in this unit are of nickel-steel, heat-treated and chamfered for silent engagement, an example of the thorough way in which the little details which make for comfort of the passengers and silent operation of the car are worked out in the entire construction. The drive to the differential is by shaft in the conventional manner through two substantial universal joints.

Both axles are of Timken manufacture, the front being an I-beam type made of 0.20-0.30 carbon steel, and the rear axle has helical bevel gears, heat-treated and ground, the driving shafts of the axle being forged from chrome nickel-steel to insure the maximum of tensile strength and resiliency under driving stresses.

Brakes are provided in two sets, in conformity with general practice, the emergency set being of the internal-expanding type and the service brakes of external-contracting construction.

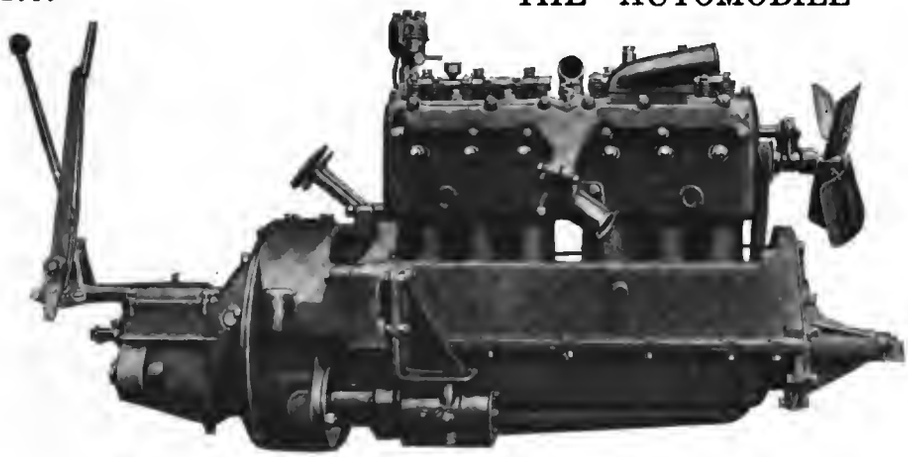
The frame, that unit of the chassis assembly which has been so often referred to as the backbone of the car, is typical of the strong though light-weight character of the construction. It is of pressed-steel channel section and made of 0.20-0.25 carbon steel, a 3½-in. kick-up at the rear insuring ample clearance over the rear axle on rebounds. To secure positive frame rigidity there are three cross-members, which are reinforced with gusset plates at the corners, all members in the assembly being hot-riveted. Springs are special alloy steel, heat-treated. Front springs are semi-elliptic and 36 in. long, and rear three-quarter-elliptic and 50 in. long. All are 2 in. wide and designed to insure comfortable riding for the passengers under all sorts of load conditions.

A wheelbase of 116 in. and 32 by 4-in. tires all around are additional factors which tend to give the Kent car its long, low, rakish appearance. The hood is high and the radiator is narrow, in keeping with the general lines of the design, and the low mounting of the body, in conjunction with the slanted windshield and raked steering wheel, impart an extremely smart appearance, an effect further accentuated by the double cowl and the horizontal placing of the top.

Equipment is very complete, some of the features which may be mentioned being top, slanting windshield, Stewart speedometer, 8-day clock and full kit of tools.

F. H. Clarke is president of the company and associated with him as directors are men prominent in the automobile, banking and other fields. As announced in THE AUTOMOBILE for Oct. 19, the Kent corporation plans to establish a plant in Belleville, a suburb of Newark, costing more than $500,000, and having potential capacity for 50,000 cars a year. The company occupied the first completed unit on Dec. 2.

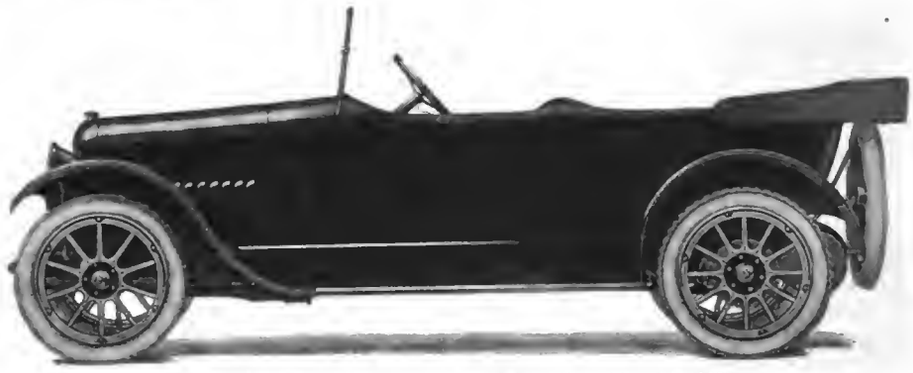
Kent power plant, showing magneto drive from generator



Falls six 3 by 4¼-in. engine used in Elgin. Note starting motor mounting

Better Springs on Elgin

New Model Improved—Heavier Frame Adopted



Four-passenger Elgin. A new model at the old price, $985

THE new Elgin six, made by the Elgin Motor Car Co., Chicago, is an improved edition of its immediate predecessor. The wheelbase is 116 instead of 114 in., and a much heavier frame is being used of the straight taper type. The springs have also had attention and the present layout is said to be extremely satisfactory. It will be noticed that the springs are mounted directly beneath the frame, and that they are practically flat, a characteristic which assists to eliminate roll. Also the springs are wider apart at the axle end than at the front end, since they follow the taper of the frame, and this certainly is a factor in their action on the road. The rigid frame, relieving the body of all stress, is contributory to the easy-riding qualities.

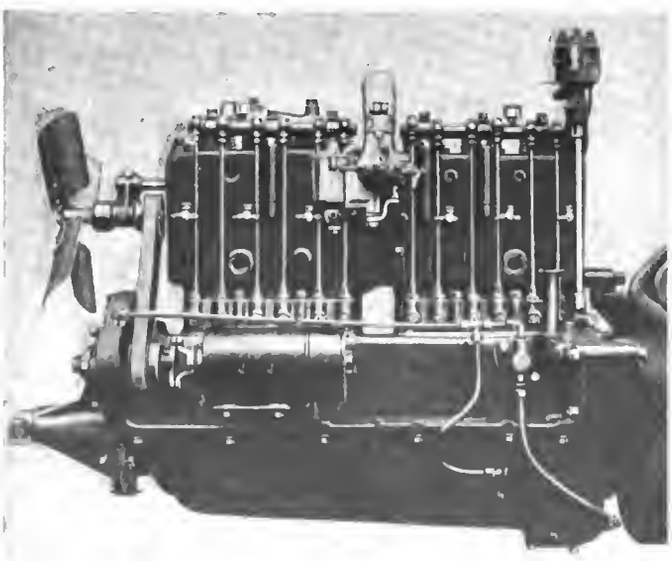
Overhead Valve Engine

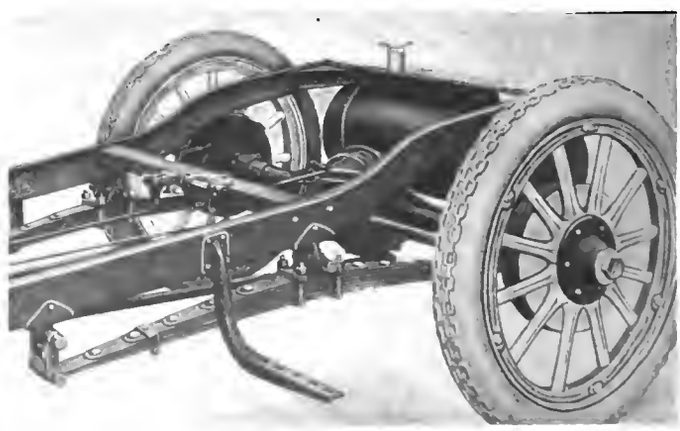
The power plant consists of a Falls engine with six cylinders 3 by 4¼ in., a Borg & Beck clutch and a three-speed gearset. The clutch is new to Elgin practice, and the ignition has also been changed to a Remy equipment with vertically mounted distributer. Wagner now supplies the generator and starting motor, the latter having Bendix flywheel engagement.

As shown in the illustrations, the engine has overhead valves operated from the camshaft by long push rods, and the valves come away together with the cylinder head. Lubrication is by combined pressure and splash and cooling is by thermo-syphon circulation.

The rear springs being cantilever a torque arm is, of course, used. The rear axle is full floating with a pressed steel housing and the complete differential with the spiral bevel gear can be removed without taking off the wheels.

The touring body seats five passengers and has a center cowl. It is upholstered in leather and the color is dark blue. The running gear is black but the wheels are painted light cream, with black striping. A new body is a four-passenger with divided front seats. This is finished in gray and has a rear deck underneath which there is plenty of luggage space. In a general way, the lines of the two bodies are strongly similar. For both cars the equipment is the same, including Jiffy curtains, Stewart speedometer, a motor-driven horn, and extra rim for the 33 by 4 tires. The price continues $985.





Above is the rear of the Elgin six-cylinder chassis, showing cantilever springs attached directly beneath the frame member. They are practically flat, which aids to eliminate roll. Note fuel tank mounting

At the left is the intake and valve side of the Falls six engine used in the Elgin, showing valve action and generator mounting

Otis Axles for 3½ and 5-Ton Trucks

Both Models Floating—Casing a Single Steel Casting —Straight Overhead Worm Used in Unit Assembly with Gear—Cast Steel Wheels Also Manufactured

THE latest addition to the ranks of manufacturers of truck axles is the Otis Elevator Co., New York, which has, of course, many years' experience in the production of worm gearing.

The Otis axles are at present being made for 3½ and 5-ton trucks, and are both of the floating type with a single cast-steel casing extending from hub to hub. This casting is made from electric steel in the Otis company's own foundries, and the manufacturers state that particular care is taken in the annealing process. Chrome-nickel steel tubes are forced into the casing at either end to carry the wheel bearings, a pressure of 20,000 lb. being used. The worm and gear are mounted as a unit assembly on a plate which bolts to the main casing, this assembly being spigoted in the case both above and below, so as to obtain a proper register and insure correct alignment. The worm itself is of the straight type, the manufacturers saying that this has been preferred because with it adjustment is unimportant except in a direction at right angles to the axis of the worm.

Timken Bearings Employed

Either Timken roller or ball bearings are used, at the choice of the purchaser. When the roller bearing is used this is mounted in such a way that expansion of the worm shaft tends to loosen the bearing. With ball bearings, one end of the worm shaft is supported in an annular bearing and the other end as a double thrust bearing.

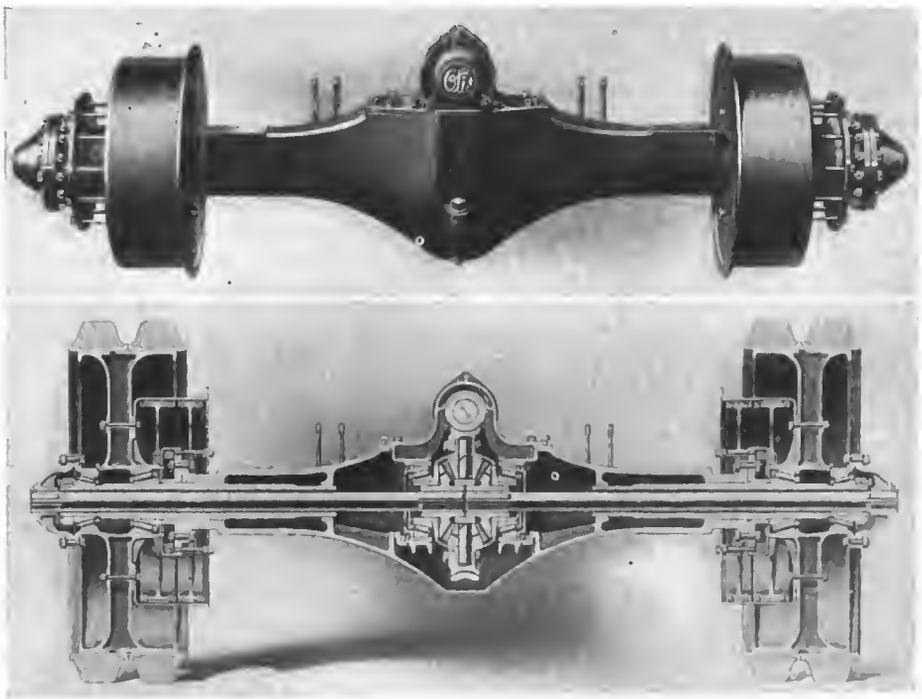
For the worm wheel bronze is, of course, the material employed, this being attached to an electric steel differential casing carrying the bevel pinion spider. The side gears of the differential are splined so that the drive-shafts are removable from the hub end of the axle, and it is noteworthy that an ample counter bore is used so as to make the engagement of the shafts easy when they are being put in place. In place of the bevel differential, one with spiral gears can be fitted if desired.

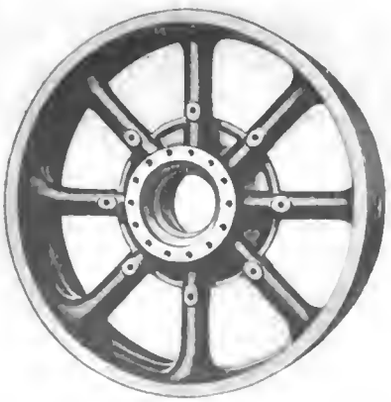
Both the brakes are internal, the drums being steel deeply flanged to prevent distortion. It is stated that the brake surface provided is exceptionally large and the way in which each brake shoe is mounted on a separate pin is of assistance both in smoothing the action of the brake and making the wear even. Great care has been taken with the detail of the brake work, the expanding cams and all other parts being hardened on their wearing surfaces.

Oiling Level Positive

For the road wheels, Timken roller bearings are used, the wheel hub having a plug for the insertion of lubricants. Oil for the worm is inserted through the filling plug at the center of the casing, and this is at such a height that only just the right amount of oil can be put in.

The Otis company is also making electric cast-steel wheels of European type, and announces that it is able to undertake large orders for these at the present time.





Above are illustrated exterior and section through the floating rear axle design produced by the Otis Elevator Co. for 3½ and 5-ton trucks. The casing is a single electric steel casting from hub to hub and the straight type worm is mounted in a unit assembly with the gear on a plate which bolts to the main casing. Chrome-nickel steel tubes are forced into each end of the casing under 20,000 lb. pressure to carry the wheel bearings. At the right are two examples of the steel wheels produced by the Otis concern, these being commercial vehicle types. They are of electric steel and are of cast construction

Six Johns-Manville Speedometers

Five Are New Models—Season Odometer 10,000 Miles—Trip Reset Improved

Special design to be standard equipment on 1917 Dodge Bros. cars

New model with flush ring for mounting on instrument boards

Combination instrument board and speedometer for Ford 1916 and 1917 cars

SEVERAL improvements in design and construction will be features of the speedometers to be produced for 1917 by the H. W. Johns-Manville Co., New York. The line consists of six models, five of which are new. There is a special design, which will be regular equipment on Dodge Bros. cars during 1917 with fittings as heretofore for transmission drive; a standard model for flush mounting; and a standard model for bracket mounting suitable for all makes of cars; a combination instrument board and speedometer for 1916 and 1917 Ford cars; another model for Fords, which is flush mounted in a suspension plate and attaches to the windshield strip; also a continuation of last year's bracket-mounted type for Ford cars. All models have 3¼-in. dials with 60-mile speed scale.

The chief difference in construction for 1917, in addition to the standardization of dials to 3¼ in., is the use of a new 10,000-mile season odometer movement instead of the 100,000-mile movement previously used. This change permits of making the odometer mileage figures larger, so that they may be more easily read. The previously used trip odometer reset mechanism, comprising a knurled wheel, projecting through a slot in the flush mounting ring in conjunction with a pressure button for engaging the reset wheel with the interior mechanism of the odometer, which construction necessitated the use of two hands when operating it, has been eliminated.

In place of this a new reset mechanism, simpler in construction, neater in appearance and much more rapid in operation and necessitating the use of only one hand to manipulate, has been adopted.

A simple knurled stem, projecting through a flush ring, operates the trip reset mechanism by merely pushing in and turning the knurled stem. With this construction the trip odometer is reset 2 or 3 miles with every turn of the stem, while with the previously used construction, the resetting process was very slow, as the odometer could only be set back a few tenths of a mile with each manipulation of the knurled wheel.

The Johns-Manville company finds that the trend in speedometer dial finish is toward the use of a black dial with white figures. For 1917 the company is prepared to furnish dials in this finish, as well as in the silver finish with black figures, which have been previously used to a large extent. All Johns-Manville instruments for the coming year will be externally finished in black and nickel and will embody a 60-mile speed scale, 10,000-mile season odometer and 100-mile trip with tenth figures in red.

The operating mechanism is unchanged from previous practice, being of the centrifugal governor type and using three accurately balanced brass weights, fastened with links to brass spiders, one of which is slidably mounted on the governor shaft, making a unit assembly of the governor mechanism with the driving spindle. The weights are controlled by a suitable spring and are caused to extend or dilate by centrifugal force, when the shaft carrying these weights is revolved through the medium of a flexible shaft and gears, connected to the road wheel. The spring is so calibrated in relation to the weights that they will diverge approximately in proportion to increases in speed and through the medium of suitable leverages or cams. This divergence is translated into miles per hour speed indication on a graduated dial.

Odometer drive is by worm and gear.

The entire interior mechanism is assembled as a unit on the cast frame before being put in the shell or casing. This unit can be lifted out of the shell, allowing of easy inspection.

The interior mechanism of all Johns-Manville speedometers is thoroughly lubricated when assembled, which lubrication is sufficient to last during the life of the instrument. The main points lubricated are the ball bearings at the top and bottom of the driving spindle, the gear and worm shaft, and the sliding sleeve on the driving spindle.

The special type speedometer for Dodge Bros. cars is called model 113H and is mounted flush in the dash without the aid of the usual flush ring, being held in place by three oval-head countersunk machine screws, which pass through the dash and enter nuts, permanently secured to three metal supporting clips, attached to the instrument case. The trip reset stem on this model projects through the dash at the right of the speedometer. The dial is black with white figures, graduations and speed indicator hand.

Model 101H is similar to that already described, except that it is provided with a special flush ring to make it suitable for flush mounting on various types of instrument boards. The type of reset on this instrument

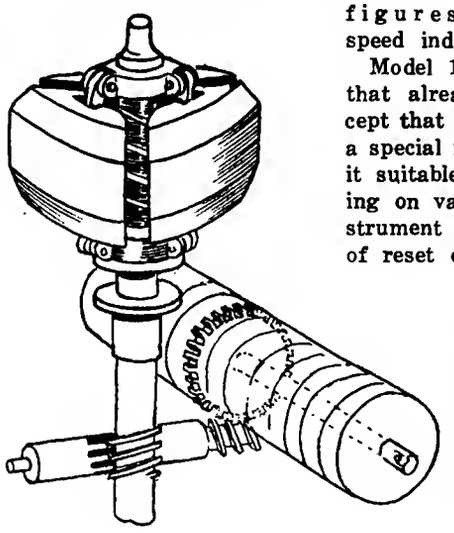


Diagram of centrifugal governor, shaft and gears used in the Johns-Manville speedometer. The cross shaft which transmits the drive from the vertical spindle to the odometer gears is also shown

is the same as on model 113H, except that it projects through a hole in the side of the flush ring to the right of the speedometer. The list price on model 101H, including fittings for front wheel drive, is $25.

The only difference between model 101H and model 101AA is that the latter is provided with either a rigid or adjustable type of dash bracket for mounting in any position desired to suit the car owner. In this instrument the trip reset stem projects from the right side of the case. Furnished complete with fittings for front wheel drive, this model sells for $25.

Special fittings can he provided to drive any of the three instruments mentioned from the transmission or universal joint, in addition to the front wheel drive.

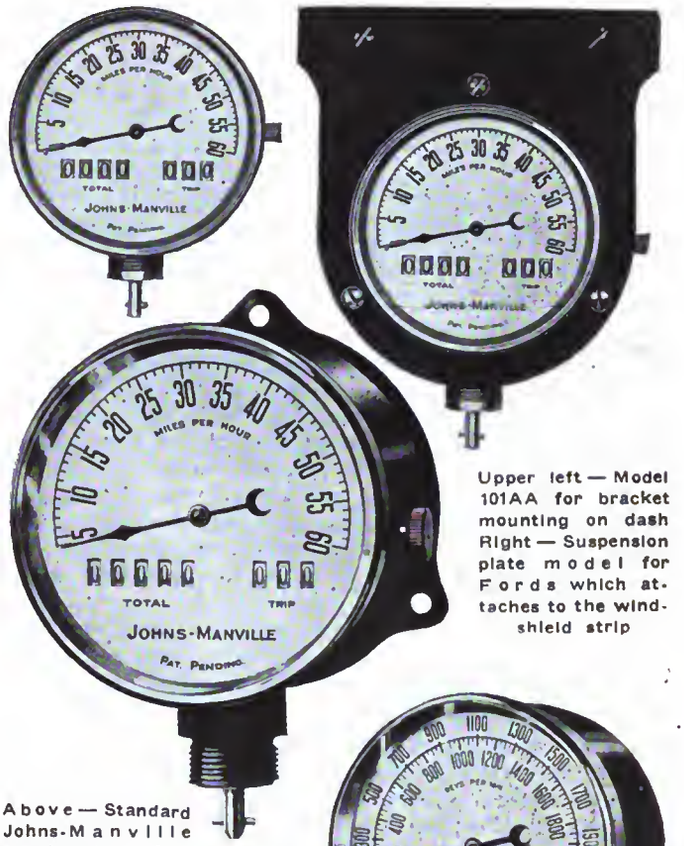
The Ford car model especially featured is the combination instrument hoard and speedometer, the two heing sold only together and called model 3009. The board is of maple, finished in dull black, to prevent any reflection of light rays into the face of the driver, and to match the Ford body. Adjustable metal and brackets are provided to compensate for variations in the width of Ford bodies. The instrument hoard also permits of mounting other instruments, such as clocks, starter switches, carbureter controls, etc. On this model the trip reset stem is hehind the instrument board, and is readily accessihle for operation. The speedometer is fiush-mounted on the hoard and is finished in black and nickel, with a hlack dial, white figures, graduations, and speed indicator hand. Instrument board speedometer and fittings complete list at $11.25.

Another new speedometer for Ford cars is the suspension plate model, which emhodies an instrument as previously described, except that the instrument is mounted flush on a hlack finished metal plate, which permits attaching the instrument to or from the windshield strip, thus mounting in a position where the speed of the car or the number of miles traveled can he easily read.

The trip odometer resetting stem projects from the right hand side of the speedometer case, and is readily accessihle for operation. This consists simply of pushing in the knurled reset stem and revolving same until the desired mileage figure is attained. Price, complete with all fittings, $11.

The other instrument for Fords, known as model 3000, is a continuation of last year's model 2001D, and has the dash bracket riveted to the back of the case. This instrument continues the use of the 100,000-mile season odometer, and is finished in black and hrass, having a white dial with black figures, graduation and speed indicator hand. It also differs from the other models in that it uses a larger knurled trip reset stem. With all fittings this model sells for $10.

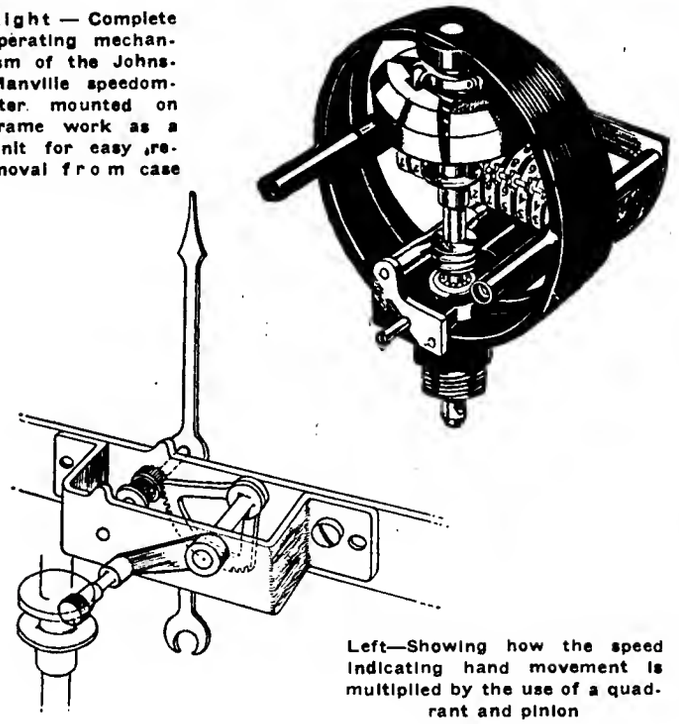
All three instruments for Ford cars can be furnished with straight or spiral swivel drive gear sections.



Upper left — Model 101AA for bracket mounting on dash Right — Suspension plate model for Fords which attaches to the windshield strip

Above — Standard Johns-Manville speedometer for Fords with dash bracket and continuing the 100,000-mile odometer

Above — Tachometer for measuring crankshaft r.p.m. Made in four styles Left—Hub odometer for trucks



Right — Complete operating mechanism of the Johns-Manville speedometer mounted on frame work as a unit for easy removal from case

Left—Showing how the speed indicating hand movement is multiplied by the use of a quadrant and pinion

Huh Odometer and Tachometer Continued

The company is continuing the manufacture of the Jones hub odometer, which will be known as Johns-Manville in the future. The hub odometer is designed for truck use and has a 100,000-mile odometer movement. Prices are: Larger model, $20; type for Ford commercial vehicles, $15.

The tachometer is made in four models to show r. p. m. of engine shafts from 50 to 4000. The instrument is of practically the same construction as the speedometers except that the odometer movement is omitted, and the calibration and dial are different. Price, $30 in a 3¼-in. size and $40 in the 4-in. model.

Many Unique Points in Harroun

Lubrication System Includes Oil Radiator—Frame Is Particularly Rigid—Stroke to Bore Ratio 1.63—Cantilever Rear Springs With Inclosed Propeller Shaft

THE Harroun Motor Co., Detroit, Mich., a concern whose entrance into the manufacturing field has been awaited with so much interest, is about to produce a car selling for $595 possessing a number of striking engineering features. Dealing first with the specification, the engine is a four 3¼ by 5¼ in., and with overhead valves. The three-speed transmission and cone clutch are combined with the engine in a unit; the rear springs are cantilever; the bodies include a five-passenger and a three-passenger roadster at $595 and a sedan for $850, the wheelbase being 107 in. in each case.

Valves at an Angle

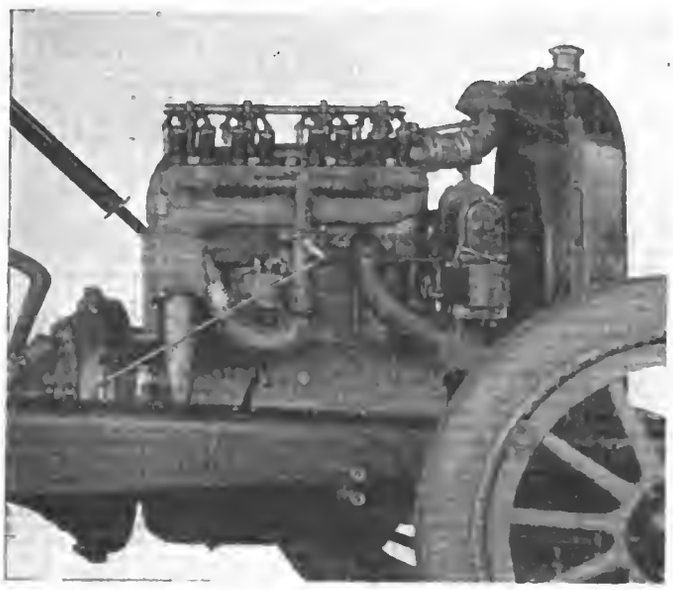
The cylinders have a detachable head and the valves are set directly in it, but an unusual feature is that they are at an angle instead of having their stems vertical. This allows the sparking plugs to be placed symmetrically with the valves, also in the head, thus following racing practice, such as might have been expected from Ray Harroun. The camshaft is in the conventional position in the crankcase, which is integral with the cylinders, and the valves are operated by push-rods and rockers. The camshaft is on the left side of the cylinders and the valves on the right, so the rockers are of considerable length. They are fulcrumed on a longitudinal shaft mounted above the cylinder outlet water header, and in this respect the engine is unique, there being no other like it in America or in any other country.

Exhaust gases go direct from the valve ports to the four-flange manifold, and a two-flange intake manifold is bolted to the cylinder head immediately above the exhaust branch, where it receives plenty of heat. The carbureter is a vertical Bell instrument, and there is a short length of vertical pipe leading to the horizontal portion that connects the two cylinder-head orifices. As shown in the illustration, the exhaust pipe has combined with it the stove providing hot air for the carbureter, and the instrument itself is so located that it will be kept fairly warm in its entirety.

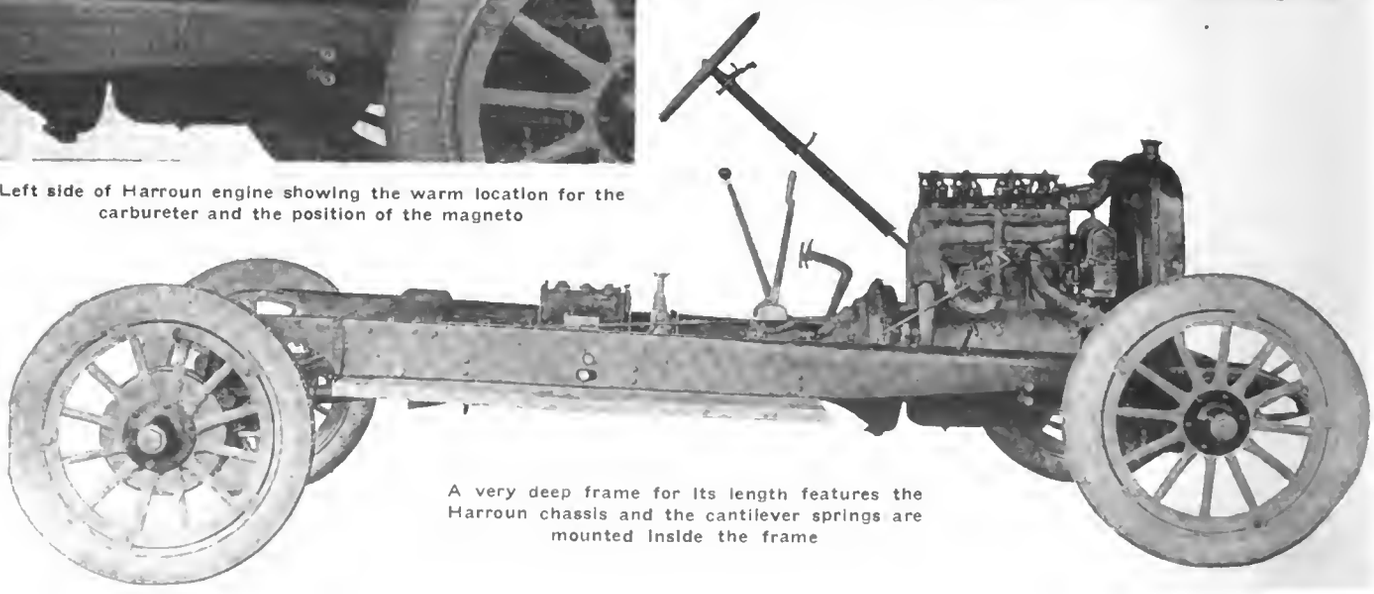
In the same illustration of the engine it can be seen that the thermo-syphon circulation is arranged so that the cool water enters just below the valves, so that the main flow is around the valve seats, where it is most required. On this side of the engine there is nothing except the carbureter, which is thus rendered ideally accessible. The end of the magneto shown in the carbureter side picture is that farthest from the wiring and contact breaker.

Ignition and generator current for battery charging are provided by a new Bosch instrument which has a magneto of the usual sort combined in one unit with a permanent magnet generator. This is mounted transversely at the front of the engine and its shaft is driven by a helical gear which meshes with the large timing gear, but in a plane at right angles to the latter. In other words the helical gearing acts as skew gearing also.

Lubrication is complete, there being a pump which supplies the main bearings by direct feeds that keep filled large cups above each bearing. Separate supplies are also taken to the camshaft and to the dip troughs beneath the connecting-rods.



Left side of Harroun engine showing the warm location for the carbureter and the position of the magneto



A very deep frame for its length features the Harroun chassis and the cantilever springs are mounted inside the frame

As it comes from the sump the oil is sucked through a long, cast pipe, located on the side of the crankcase and having fins on its exterior, this being the oil cooling device. The pump is a plunger type and is driven direct off the camshaft, but it is operated by a proper eccentric and strap instead of by a cam and a spring in the conventional way.

The crankshaft is unusual also, as the middle bearing is about a half inch bigger than either of the end bearings. It is a narrow bearing and this coupled with the large diameter should make the shaft about as rigid as it well could be. The engine is a remarkably easy assembly proposition. It should be noted that the pistons at the top of the stroke come level with the top of the cylinder block, which means that all the combustion spaces are machined out of the head casting. Care is taken to have the spaces of exact size, so that compression in one cylinder is the same as in any other.

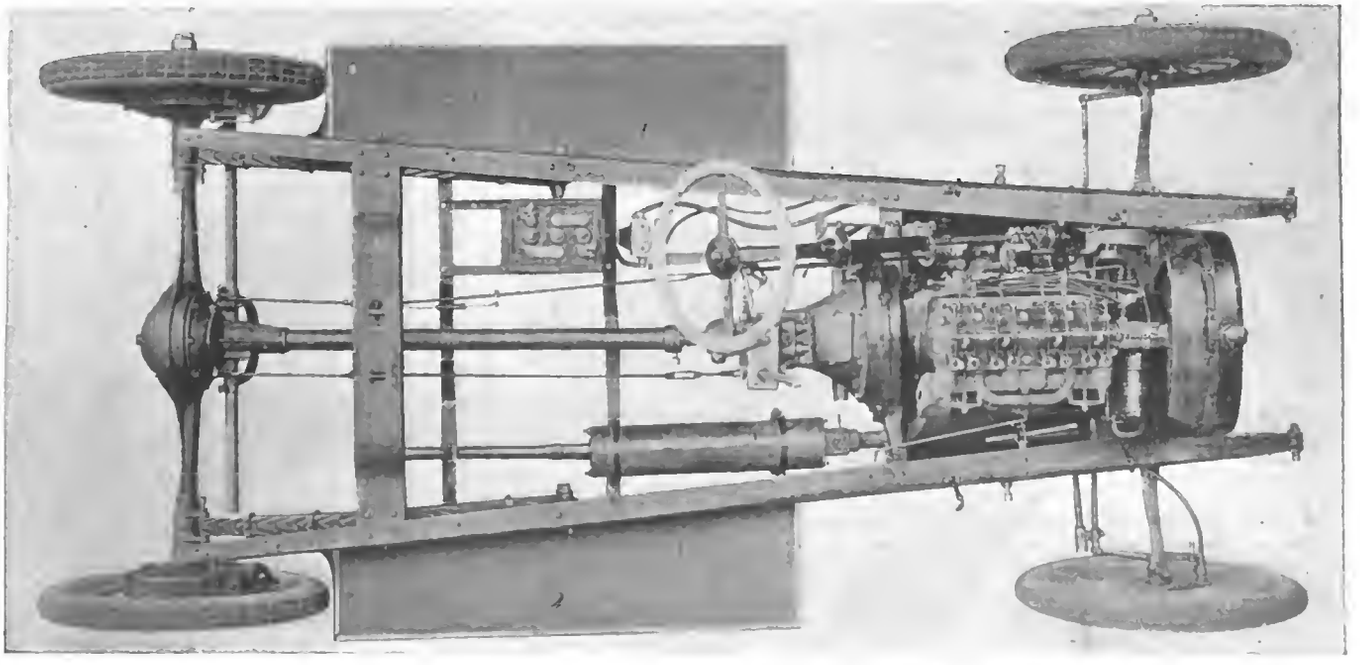
Five-passenger Harroun Four with standard equipment

About the pressed steel cone clutch and the three speed gearset there is nothing very remarkable, save, perhaps, that compactness in design is exhibited to an advanced degree. Behind the gearset there is a single universal, and then a torque tube to the pressed steel rear axle housing. This torque tube ends just behind the universal and has no frame connection whatever. There is an interesting detail of the brakework than can be seen in the chassis plan. The hand lever operates a solid shaft running from brake to brake right across the axle. So the hand brake mechanism is reduced to a simple pull rod and a plain cross shaft with one little lever on it. The foot brake is operated by tubes outside the shaft just mentioned, and there are two levers, one on each tube at the inner ends. These two levers are linked together by a yoke, seen in the chassis plan, which solidly connects the two tubes. It will thus be seen that there is no equalization in the brakes, many parts and a good deal of weight being saved in this elimination.

Of course, one of the features of the car is the frame which is so deep that the running board bolts right up against it without any sheet metal shields. The running board irons go right across the frame from side to side, thus acting as cross members and stiffening the frame very greatly. It is one of the most tapering taper frames ever built, and the way in which the cantilever springs are mounted inside the frame sections is also novel. These springs are also given a "spread" at the rear, and this is claimed to aid the spring action by damping out side stresses.

Yet another departure from conventional design is found in the steering. First, the steering gear is bolted to the crankcase, instead of to the frame, and the connecting-rod works across the frame instead of fore and aft. This allows the gear to be placed far forward, giving the column a good rake. The wheel itself has leaf springs as spokes, these being claimed to damp vibration and to make the wheel pleasant to hold for long periods. Furthermore the steering gear can readily be mounted on either the right or left side, the whole car being designed so that it can be made either way without special parts.

In the body a conventional outward form has been adhered to, and the finish is a green with which the khaki top contrasts. The driver and front passenger have not been neglected for the sake of the tonneau occupants, so that any one of the five seats is as good as another. All the usual things come with the car, but the inclusion of both a clock and a speedometer is not conventional on so low-priced a vehicle.



Plan of Harroun Four chassis, showing cross member step irons and wide flare on taper frame

King Adds Four-Passenger Model

Foursome Is Development of Club Car Idea—Is Mounted on Standard Eight-Cylinder Chassis Which Is Altered Only By Refinements—Touring, Roadster and Sedan Are Improved

UNDER the model number EE the King Motor Car Co. has continued with refinements the No. E eight made last season. One addition has been made to the line in the shape of a new body of four-passenger capacity. Other than this the changes in the King cars are chiefly in minor refinements of a mechanical nature and slight alterations in body detail.

The new four-passenger King is a development of the club car idea, with the objectionable points removed. The body provides plenty of room in the rear compartment, giving all the advantages of the close-coupled touring design with the lines of the roadster preserved. The other three bodies on this chassis, the seven-passenger touring car, three-passenger roadster, and seven-passenger sedan, have also been refined in construction and appearance in bringing the models up to the standard set for the 1917 season.

No Radical Changes

Mechanically, there are no changes which rank as important or radical. The brakes have been improved, there is a new gasoline system, the Stewart vacuum, the radiator is larger and better shaped, the tie rod yoke has been redesigned and there are one or two small alterations in the crankshaft.

The brake changes affect both the service and the hand brake, the latter being mounted as in previous King models on the end of the transmission shaft. The change is the insertion of a spring link in the line, so that any desired tension can be placed upon the brake linkage, thus tightening the brake as firmly as desired and allowing the car to be left safely upon any gradient without danger of rolling. On tightening the brake it is possible to set the brake as it would be with the ordinary type of linkage and then upon further pull on the hand lever, the brake can be tightened four more notches on the brake quadrant.

On the foot brake the change is in the insertion of an equalizing mechanism at the rear, it was formerly solid from the pedal all the way back to the brake levers on the rear axle.

On the engine there has been two slight alterations in the crankshaft. These are in the increase of the thrust flange area at the center bearing and in the use of a crab for holding the valve tappet guide in place. The shaft has a diameter of 1 13/16 at the center bearing and the flange originally had a diameter of 2⅝ in. The diameter is now 3½ in. This about doubles the area of the thrust surface on the center bearing. This is a three-bearing shaft with side by side connecting-rods.

The use of the crab instead of the plate formerly used has the advantage of not tending to bind the guide for the tappet. Another change which is rather part of the oiling system than of the crankshaft is the installation of an oil throw-off at the rear bearing. This is in the form of two grooves, and after the oil is thrown from the shaft it drains back to the crankcase and joins the other circulating oil. There are no other changes in the oiling system.

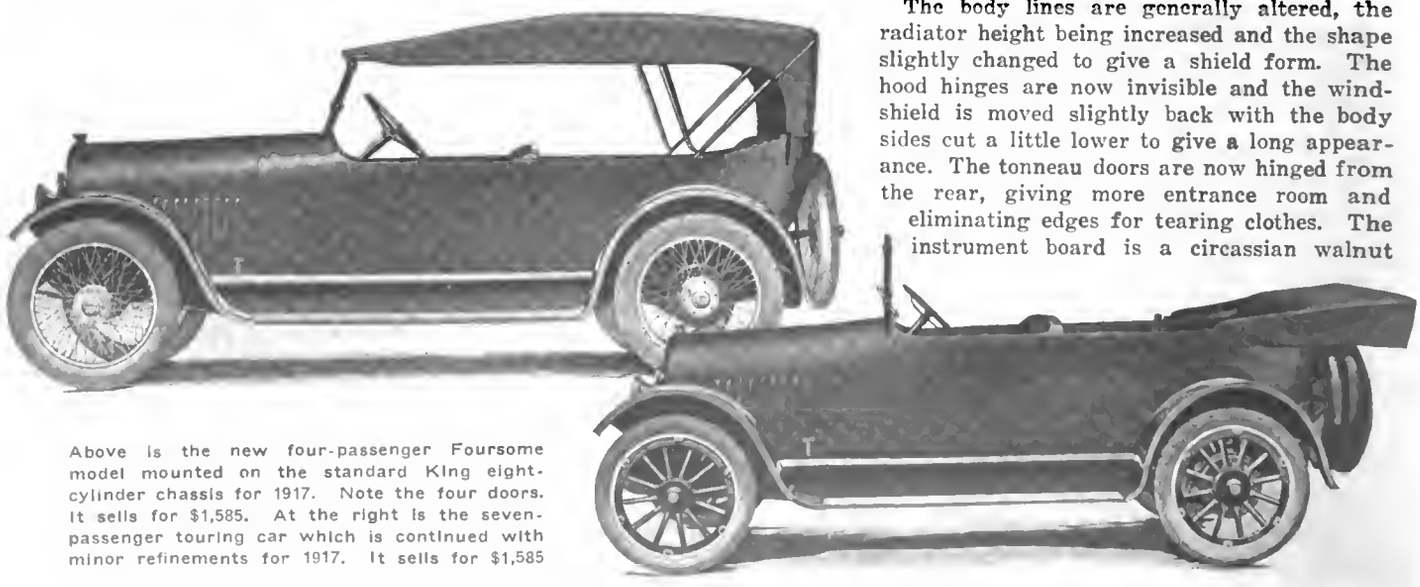
One of the alterations of detail which represents a valuable addition to the safety of the car is in the connection of the tie rod end to the steering arm. This is now a forked yoke connection with a bearing both above and below. In addition to the larger bearing space provided, the yoke connection is better connected to the cross arm by means of two clamp bolts instead of one.

A minor detail which is illustrative of the care taken to prevent rattles is in the use of a full length steering column sleeve which now extends from the wheel to the steering gear housing whereas it formerly only went down as far as the dash.

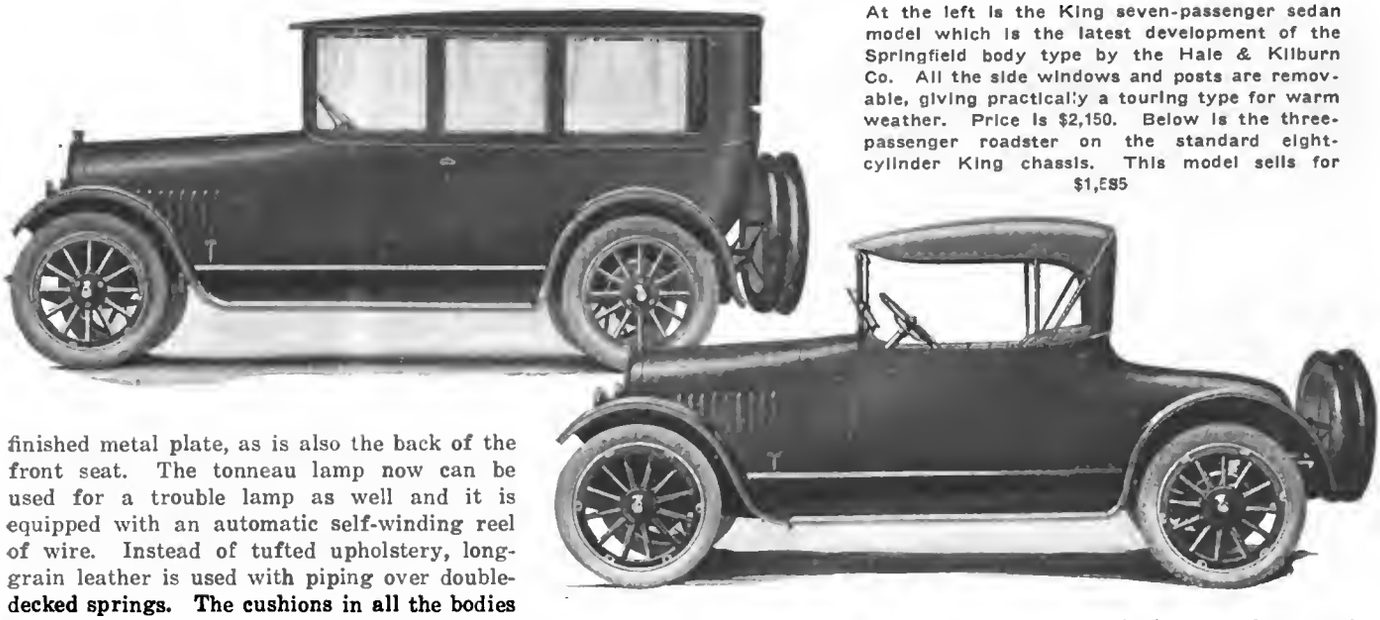
Line Now Complete

In putting the four-body line upon the single chassis, a complete range of cars is given. The price is $1,585 for the seven-passenger touring, four-passenger foursome and three-passenger roadster and $2,150 for the sedan.

The body lines are generally altered, the radiator height being increased and the shape slightly changed to give a shield form. The hood hinges are now invisible and the windshield is moved slightly back with the body sides cut a little lower to give a long appearance. The tonneau doors are now hinged from the rear, giving more entrance room and eliminating edges for tearing clothes. The instrument board is a circassian walnut



Above is the new four-passenger Foursome model mounted on the standard King eight-cylinder chassis for 1917. Note the four doors. It sells for $1,585. At the right is the seven-passenger touring car which is continued with minor refinements for 1917. It sells for $1,585



At the left is the King seven-passenger sedan model which is the latest development of the Springfield body type by the Hale & Kilburn Co. All the side windows and posts are removable, giving practically a touring type for warm weather. Price is $2,150. Below is the three-passenger roadster on the standard eight-cylinder King chassis. This model sells for $1,595

finished metal plate, as is also the back of the front seat. The tonneau lamp now can be used for a trouble lamp as well and it is equipped with an automatic self-winding reel of wire. Instead of tufted upholstery, long-grain leather is used with piping over double-decked springs. The cushions in all the bodies are 10 in. in thickness, this making for extreme comfort.

Just inside the windshield there are placed louvres for ventilation in warm weather. The top is better finished with a German silver binding at the front and rear. The top now fastens to the windshield with an automatic catch and the top material is the De Luxe Neverleak.

In the Foursome body, the four-passenger roadster idea is departed from in that there are four doors. Everything has been done to get low rakish lines, the windshield, for example, being sloped to an angle of 20 deg.

The Seven-Passenger Sedan

The seven-passenger sedan is the latest improvement of the Springfield type, manufactured by Hale & Kilburn Co. All the side windows are removable as well as the posts, giving practically a touring car with top up when desired for warmer weather. The seating arrangements are the same as for the seven-passenger touring car with the exception of the front seats, which are divided.

The chassis remains essentially the same. The unit power plant includes a V-type 3 by 5-in. eight, fitted with Atwater Kent ignition, Ball & Ball carbureter and Ward Leonard lighting and starting, with Willard 6-80 battery. The tire equipment is 34 by 4 with non-skid rear and wire wheels optional at $100 extra. The wheelbase is 120 in.

A plate clutch is used transmitting the drive through a three-speed gearbox, two Spicer joints and propeller shaft to a floating axle. The drive is taken through the 48-in. rear cantilever, but the torque is taken through a separate member of triangular design.

Using Old Tires

By Charles Vivier

JUST as the best chain fails at its weakest link so does the best tire fail at its weakest spot. It seems that in the majority of tires the carcass is much weaker than the tread; as a matter of fact, a casing subjected to ordinary touring use blows up within 25 to 30 per cent of its ultimate possible mileage, when a few thousand miles of perfectly good rubber still remain unused. Through neglect or accident, the blow-out occurs much sooner. Among the chief causes which are conducive to premature blow-outs, touring conditions considered, are under-inflation of casing when new and over-inflation when old, glass cuts, stone bruises and also tangential nail punctures. The modern pneumatic tire possesses remarkable wearing qualities which are unfortunately equalled by the high cost of the finished product. With the present price of gasoline, motoring costs about as much for tires as for fuel and oil; therefore, it behooves the motorist to save on tires as well as on fuel; to get the largest tire mileage with the least cost.

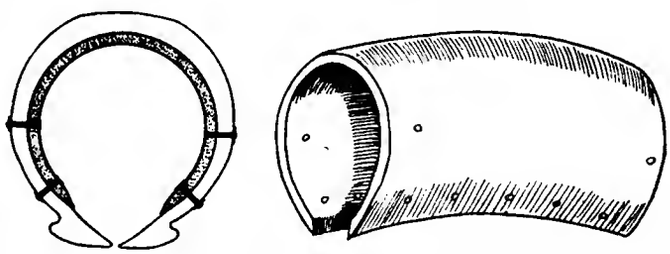
Repair Is Cheap

A blow-up casing can be efficiently and inexpensively repaired by riveting on the inside a patch (made from an old tire of the same size), covering the injured part. All the tools necessary consist of a hammer, a riveting tool and a leather punch; the material; some copper rivets and patches, according to the size of the casing to be repaired. Of course, such a riveting task is not very easy, especially for large size tires, but any one who has elementary notions about riveting leather can do a neat and dependable job, proceeding as follows:

Simple Materials

For a 4½-in. tire, for instance, get 1-in. copper rivets and burrs; hammer the ends of the rivets to a sharp point. For the inside patch, get a sufficiently large section (with the bead and rubber removed) from a discarded 4½-in. tire. Punch a few ⅛-in. holes, for the easy insertion and driving of rivets, about 2½ in. apart on each edge of patch, as per illustration. Then hammer or force the rivets into a riveting position, taking care that the patch is not too loose nor too tight when the tire assumes its normal curve.

This method can take care of a fairly serious blow-out, no matter if the wound is near the bead or across the tire. As 15 to 20 cents' worth of rivets are sufficient to repair an ordinary blow-out on a 4½-in. tire, the riveting process compares most favorably with the more expensive jobs of vulcanizing or of sewing two old casings together, in the approved manner.



Simple method for using up old tires described by Chas. Vivier

Maxwell Adds 1-Ton Truck To Line

25,000 To Be Built on Standardized Production Plan—Three Body Models To Meet All Requirements

ALL the manufacturing facilities of the Maxwell Motor Co., embracing the three plants at Detroit, Dayton, Ohio, and New Castle, Ind., will concentrate on the new 1-ton Maxwell truck as well as on the passenger car. A manufacturing program of 25,000 trucks has been embarked upon, and the distribution will be taken care of through the regular Maxwell channels.

Three standard body models will be mounted on the 1-ton chassis, designed to meet the needs of practically any line of business. The field which it is intended to serve includes such trades as the grocers, dry goods, meat dealers, laundries, bakeries, baggage and transfer companies, hardware dealers, painters, hauling contractors, builders, lumber dealers, and a wide variety of other vocations where a 1-ton truck will be suitable.

Coincident with the manufacturing plan, an elaborate service scheme has been laid out so that in all parts of the country owners will be able to get repair parts on short notice. The Maxwell organization of 3000 dealers and branches will maintain service stations for Maxwell trucks as well as for the passenger cars, and they will be at all times required to keep a supply of spare parts on hand. The warehouse system will also be used, so that regardless of the location of the dealer he will be able to be supplied with spare parts on 12 hr. notice.

Chassis Parts Like Passenger Car's

A standardized production scheme which fits in well with the Maxwell quantity production methods can readily be used in connection with the truck and passenger car, as the majority of the chassis parts are the same. In fact, the design is similar to the passenger cars throughout, except for the rear end. The truck has a 124-in. wheelbase and is so arranged that the major part of the load falls on the rear axle. The chassis frame work and rear end are strongly constructed for heavy-duty work. The wheels are 32 by 3, equipped with solid tires, in front, and 32 by 3½, with solid tires, in the rear. The body platform is 8½ ft. long.

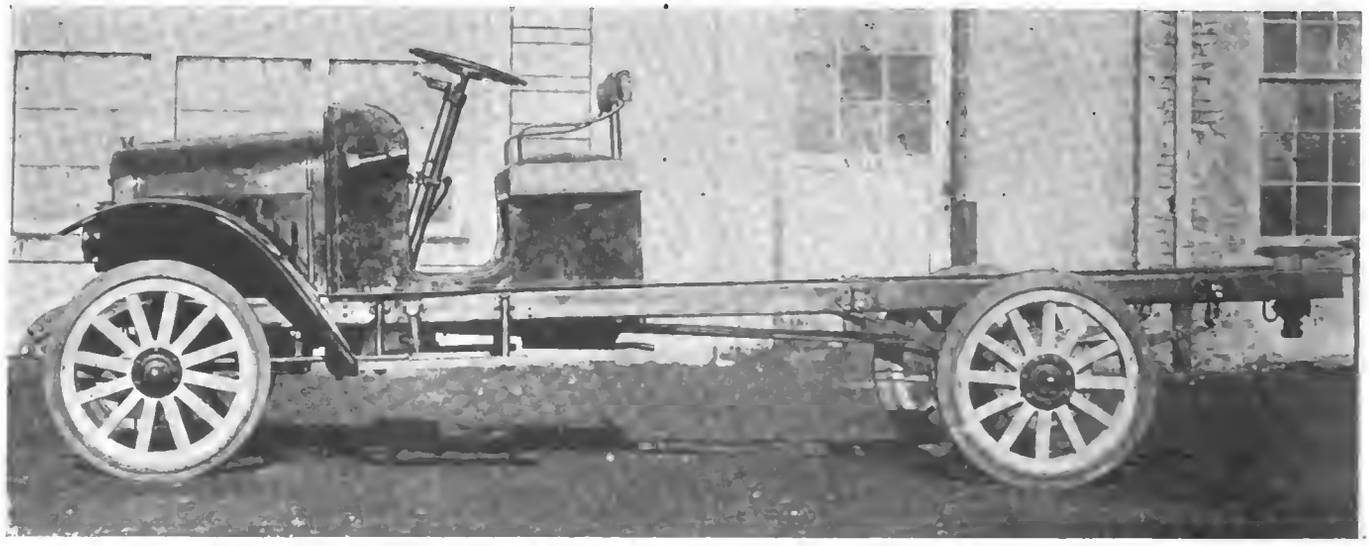
Worm drive is used for the rear transmission in connection with a three-quarter-floating axle housed in an exceptionally rigid malleable-steel housing. Heavy artillery truck wheels are used and circled by steel rims and carried upon heavy-duty roller bearings. Another feature of the chassis, which shows the care used in securing the greatest possible strength and rigidity, is the heavy cross-members which are riveted and strongly bracketed to the side channel members of the frame. Semi-elliptic springs front and rear also are of special design to take the particular stresses which will fall upon a truck of this size subjected to continual running over all sorts of road conditions and at speeds in excess of what is general practice in truck usage.

The Three Body Styles

The three body lines are regulation box style, an open express and a screened express. The same style of chassis and cab is used for all three, and, if need be for certain lines of business, more than one body can be had for a chassis, thus giving an opportunity to use the particular style of body desired with the work in hand. The open express lists at $805; the screened express, equipped with a roof and side screens, at $845, and the regulation box, provided with a continuous roof, at $840. The chassis sells for $760.

The same power plant used in the Maxwell passenger car is employed. It retains its bore of 3⅝ in., with a stroke of 4½ in., and has a formula rating of 21.1 hp. and a displacement of 185.8 cu. in. The cylinders and the upper half of the crankcase are cast integrally. The valves and manifolds are on the right, along with the Sims high-tension magneto.

The crankshaft is carried on two bearings, each 1⅞ in. in diameter, the front being 2½ and the rear 2 13/16 in. long. The lower rod bearing is 1⅞ by 1½. The camshaft diameter is 1¼ in., the front and rear bearing lengths being respectively 1 13/16 and 1⅜ in. The cams act directly upon flat mushroom-type followers which operate the 1 9/16-in. valve. Throughout the entire engine conventional practice rules, with all dimensions on the safe side. The cast-iron pistons



Maxwell 1-ton truck chassis, showing the substantial simplicity of the design, which is to be produced on a standardized production plan

Two types of body on Maxwell 1-ton chassis, giving a good idea of the ample length

have two rings above the wrist-pin and a scraper ring below. The piston pin is locked in the boss on each side of the upper connecting-rod bearing. The rods are I-beam sections.

Oiling is by splash, with supply carried in the pressed-steel bottom pan which when removed leaves the entire interior free for inspection. The oil is circulated by a camshaft-driven pump, being circulated directly to leads beneath the rod bearings, from where it is splashed to all parts of the engine. There is an oil-level indicator on the crankcase.

One of the features of the power plant which will be appreciated in truck usage is its accessibility. By removing the stud bolts in the head the entire top of the engine can be taken off, along with the spark plugs, exposing the valves and combustion chambers. For valve grinding and carbon removing the time spent in reaching the desired parts has been minimized. To reach the other units it is necessary to drop the engine pan, which allows the repairmen to reach the lower rod bearings or the main bearings. To remove the piston and rod assemblies the lower rod bolts can be removed by dropping the bottom of the crankcase, and the pistons can then be taken out of the top when the head is off the block.

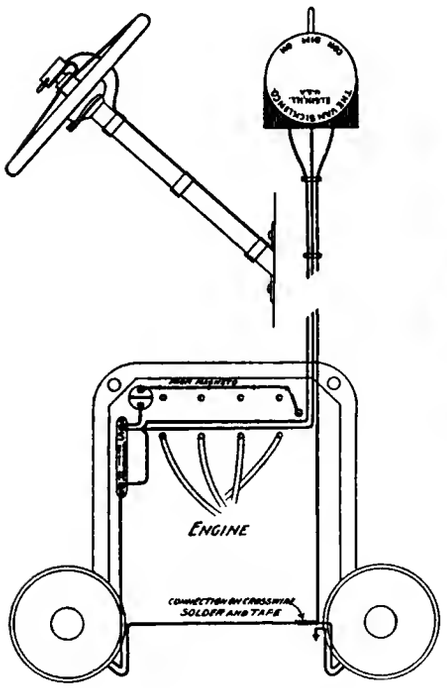
The Maxwell clutch and three-speed gearbox have been retained as used in the passenger car. The clutch is a cone, with a woven asbestos face which is oilproof. The clutch is completely housed with the flywheel in the unit plant, and operates in oil.

From the gearset to the rear wheels the propulsive units are altogether different from the passenger car. The propeller shaft, instead of being considerably longer for the 124-in. chassis, has been made more rigid by dividing its length. The drive is carried in two sections. The first member reaches a point between the axle and the gearbox, where it is supported by one of the cross-members of the frame. From this point a universal joint transmits the drive to another length of shaft which reaches the rear axle. This style of divided drive eliminates the tendency to whipping and also gives a maximum of flexibilty. It is expected by Maxwell engineers that this will prolong the life of the axle bearings, due to a reduction of the stresses ordinarily caused by the whipping tendency.

The Hotchkiss drive is used, and has been found to work out to particular advantage in connection with the divided propeller shaft and heavy truck springs.

For some time there has been considerable discussion regarding the possibility of a light vehicle which will take the place of a one-horse wagon or, to even better advantage, a number of one-horse wagons. The range of a light truck in miles per day is much greater than that of a horse vehicle, and therefore, to take advantage of this range and at the same time have the truck operate economically, it is necessary that the capacity shall balance the distance which it is able to travel.

Van Sicklen Lighting System for Fords at $4



Above — Van Sicklen dimmer and intensifier switch, showing attachment for top of Ford steering column

Above at left—Headlight switch, showing simple method of attaching. Note convenient location of headlight control within thumb-reach of the driving hand

At left—Wiring diagram of the Van Sicklen headlight dimmer and intensifier equipment, showing method of installation

COMPOSED of but three parts and so simple that it can be installed in 3 min. without interfering with the regular wiring in any way, the Van Sicklen Headlight Dimmer and Intensifier equipment for Ford cars has been perfected by the Van Sicklen Co., Elgin, Ill., and is marketed by the Beckley, Ralston Co., of Chicago. This device, which is illustrated herewith, is claimed to furnish a uniform light under all conditions, a flip of the switch to Int. giving a clear penetrating light, turning it to Dim softens it to a mellow glow which complies with all police requirements, and for ordinary conditions when the normal light produced by the Ford lighting system is desired, flipping the switch to On restores it.

Easily Attached

The addition of three short wires and the switch, which is mounted on the top of the steering column, comprise the installation, which does not require further attention when once mounted. The device sells for $4 complete.

The FORVM

Overloading and Rating of Trucks

By Edward T. Birdsall, M. E.

CAUSES—The practice of loading trucks beyond their rated capacities by owners and users has been the subject of many articles in the business press, and productive of many plans by the manufacturers of both trucks and components for its elimination, but all without substantial results.

The difficulties of regulating the abuse are many and most of them quite beyond the power of the manufacturers to cope with.

Among the principal causes of overloading are—

1—Lack of supervision on the part of the owner over the employees loading and handling the truck.

2—Lack of appreciation, or indifference, of the owner as to the evils of overloading.

3—Ignorance of the owner and employees as to the weights of the materials or items composing the load.

4—Exigencies of trade which make occasional overloading at any cost unavoidable. A few instances of this sort not followed by immediate breakage engenders confidence in the minds of the owner and employees that the truck is capable of carrying a load in excess of its rated capacity without injury.

5—Observation of instances of overloading, without apparent bad results, on the part of other users.

6—Ability of the power plant to pull the overload.

7—Statements of over zealous or mercenary truck salesmen that the truck will stand up under excess loading.

8—Fitting of oversize tires. This may have primarily been done to increase the tire life, but with an extra tire load capacity overloading of the truck soon follows as a natural sequence.

9—Natural growth of a business to a volume too great for the truck equipment, and reluctance of the owner to purchase additional units in advance of absolute necessity.

10—Willful overloading. In a few cases owners have argued that the aggregate value of overload ton miles carried, plus the sale value of the wreck, will in a year amount to a sum more than sufficient to pay for a new truck.

Requirements Vary With Trade

In addition to the above, every trade using trucks will be found to have special requirements or conditions peculiar to itself that will lead to occasional or more or less continual overloading.

Cause No. 3 is regarded by the writer as the most prolific cause of overloading.

Remedies—Much thought has been expended on plans, devices and what for a better name might be called subterfuges to remedy the evil. Prominent among these are:

a—Cancellation of the guarantee when overloading is discovered or persisted in.

b—The education of owners and users by published articles, pamphlets, advertisements, arguments and thinly veiled threats.

c—Bonus payments to drivers for maximum mileage coupled with minimum repairs.

d—Grading the springs so that by observation or effect an overload is made evident.

e—The employment of an expert to supervise the service. This, of course, is only possible where fleets are operated.

f—Indicating alarm or recording devices.

g—Use of a motor too small to pull the overload.

Of the above remedies, the use of a motor too small to pull the load is obviously impracticable.

Recording and alarm devices are soon neglected except by the manager of a fleet, in which case they only act as checks to other methods.

The bonus system to drivers I believe is good under all conditions, but must be impartially and systematically kept up. It is in the same class as "piece work rates" and must not be handled so as to bring discredit to the plan.

The springs are to a certain extent visible scales weighing the load, and can be used as rough indicators of overload.

The scheme of having the projecting body touch the tires under overload is impracticable as expensive injuries to the tires will occur, which no owner would tolerate.

The best suggestion in this line that has come to the writer's attention is to so proportion the springs that they are exactly straight or flat under the normal loads, but reversed under overloads.

Inspection Shows Condition

A mere inspection of the truck, even when in motion, at once discloses the condition of the loading. This plan to be of real value, however, necessitates the installing of special springs to fit all conditions arising from the different weights of bodies. Four or five sizes would probably cover most cases.

The writer believes that only the education of the owner and user will accomplish the end desired, and this will take a considerable time to fully accomplish. There will always be a minority of owners who will be indifferent to their welfare and impervious to argument. But the truck industry will soon be so large that the bad effect of this small class will not be felt by the industry at large. These are the same people who to-day are overloading their horse teams but obviously without the slightest effect upon the sales of the horse and wagon dealers or upon more sane owners.

It is a question whether the industry at the present time is in a strong enough position to take any drastic action in the matter. It seems that a persuasive yet forceful educational campaign which would hold a dollar bill constantly before the eyes of the owner is about all that can be done at present. The arguments against overloading should submit definite figures and not mere platitudes. They should give concrete facts and not a series of "Don'ts."

The campaign would be best inaugurated by an association of truck manufacturers, and not by individual builders, as it would thus have more weight and would eliminate the personal self-interest factor. It would also divide the burden of cost so that even an extensive and prolonged campaign would not be a hardship on any individual maker.

Rating Important

Closely allied to the question of overloading is the subject of truck load ratings. An investigation of the ratings of the various manufacturers at once discloses wide differences in the sizes and apparent strengths of the various parts on which the load rating must be based. The two components that have the most influence on the rating are the axles and the tires. The tire makers are now fairly well agreed as to the proper sizes of tires for various loads, but the axle manufacturers do not seem to be in very close agree-

ment. The tendency of the last 2 or 3 years has been to rate axles with an excessive factor of safety, if good roads and normal speeds are factors of the rating. They evidently rate them for rough roads, overloads and excessive speeds. This of course is a safety-first play for the axle maker, but works a hardship on the truck manufacturer as to costs, as the principal makers of axles refuse to sell or deliver if the advertised truck load rating is higher than their axle rating.

As the surface on which the truck travels is just as much a part of the transportation mechanism as the truck itself, it seems only logical and fair that it should be considered as one of the factors in the rating. This, however, at once raises a host of problems and complications of manufacture, selling and use that run hopelessly counter to design, production and profit.

For example: A given truck, with suitable minor changes in detail, might economically carry 4 tons at 10 m.p.h. on very good roads, but only be good for 2 tons on bad roads at 6 m.p.h. The possibilities of the truck industry when the owner's education has reached an elevation that would permit the truck builder with safety to meet such a condition, is beyond conjecture, and I fear far in the future. An examination of the trucks on the market shows clearly that some have their ratings based on good roads, have a resultant low price, and seem to be "getting away with it." Others are evidently rated for the worst roads, have a resultant high price and smaller production.

Decision Is Difficult

It is difficult, under present conditions, to decide which is right. It is comparatively easy to select and recommend a suitable truck for a particular set of conditions of operation and use, and all will be well as long as the truck is confined to its original location and use. When, however, for any reason, the truck is transferred to a new owner, location and use, then in a majority of cases trouble will develop, which under present conditions will reflect unfavorably on the manufacturer.

It would seem, therefore, that the education of the present owners and users, and the future truck-owning portion of the public, in the correct use of power vehicles is the first step to be taken.

The logical body to carry on the work of evolving a new rating is the standards committee of the S. A. E. The committee should be composed of truck makers and the findings of the committee should have the approval of at least 75 per cent of the manufacturers before making its report at the summer meeting of 1920.

Tires Pumped Too Hard

By O. B. Parkinson

MOST tires have lettered upon them the legend: "Inflate to — lbs.," inserting the figures 70, 80, 90 or 100, according to the size of the tire, and the ideas of the maker. It will be found that upon inflating a tire to the full pressure stated, that the tire becomes practically a solid tire. Many drivers when inflating their tires at a garage where air pressure is obtained, inflate their tires 10 lb. or more higher than the maker specifies, with the idea that it will save pumping again for a longer time.

Why is a pneumatic tire used? It was found that with the earlier types of cars having an extreme speed limit of not over 20 m.p.h. the solid tires with which these cars were equipped were the cause of excessive vibration which crystallized the steel of the car, shook loose the nuts and bearings, broke springs, and made the vehicle a most uncomfortable conveyance. Then came the pneumatic tire with its almost universal adoption, it being unanimously agreed that "riding on air" was much more comfortable than "riding on iron." In other words, the springing up and down of the air cushion would materially lessen the vibration, tend to eliminate crystallization, broken springs and loose nuts, and secure much more comfort for the passengers.

The Danger of Skidding

I know of no more senseless proceeding than to put a set of pneumatic tires on a car with the idea of securing ease of riding, and then to put a volume of compressed air in them to the extent that makes solid tires of them. Practically the same results follow as did with the old cars except that, by reason of better steels being used, the metal parts do not so readily crystallize and, by reason of better springs, the springs are not so often broken; but on account of the high rate of speed at which most motorists drive, there is a danger which was unknown in the early days, that of skidding, either in turning corners, or on roads where there is a slight roughness, such as an oiled macadam or asphalt road which has become "wavy." Very few accidents are the result of skidding on wet roads, as compared with those upon dry roads, as nearly all drivers proceed with extreme caution over wet, slippery pavements.

Now, anyone can easily prove to his own satisfaction, by trying it, that a car with tires inflated to 90 lb., which will skid over the dry roads as above indicated, will not skid over the same roads at the same speed, with the tires inflated to 60 lb. A machine which will not travel through sand at 90 lb. will do so at 60 lb.; likewise, a hill which it will not climb with 90 lb., it will climb with a 60-lb. pressure, Again, with a 90-lb. pressure, it is almost certain that early in the career of the tire the inner tube will be "pinched" either by being forced between the edges of the casing on the inside, or forced entirely under the casing.

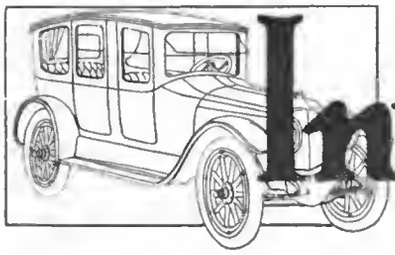
Rim Cutting Not Likely

The only apparently valid reason given for inflating tires until they resemble solid tires, is that the tires will not be rim-cut, and therefore, last longer. This is not correct. In good tires attached to rims which are now designed so that no sharp edges press against the wall of the tire, there is no rim cutting, unless the tire is run flat; and if a slightly larger mileage is obtained by pumping the tire hard, it is much more than offset in actual dollars by the cost of vulcanizing and replacing inner tubes, to say nothing of the annoyance, loss of time and energy expended in changing tires; add to this the elimination of the skidding danger, the elimination of loose nuts, bolts, and broken springs, as well as crystallization, and beyond all, for the average person, the luxurious ease of riding, and you have an array of reasons why a tire should not be over-inflated.

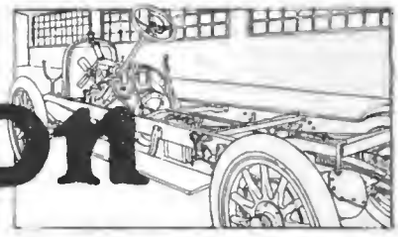
There may be some exceptions to this. There are certain tires which have been on the market but a comparatively short time, which are known generally as cord tires, on which the inflation pressure is marked at much lower figures than on the tires made in the standard fashion, and in the literature of some of these makes, it is stated that by reason of requiring less pressure, the car is easier riding, which is perfectly true.

Lower Pressure Practical

As a general rule, subject to some variations, and excepting as to cord tires, the tire should be pumped at least 20 lb. less than the maker advises. Some drivers get excellent satisfaction from rear tires inflated 20 lb. less, and front tires 30 lb. less than the maker advises. Personally, I have used a set of 4-in. tires (marked "inflate to 80 lb.") on a 3000-lb. car through mountains and over rough roads, with tires carrying not more than 30 lb. in front, and 50 lb. in the rear, and with exceptional ease of riding, the best of traction on hills and in sand and positively without any rim cutting or other injury to the tires except the ordinary abrasion of the tread.



Information



¶ With this issue of THE AUTOMOBILE the Rostrum, as a department devoted to answering the questions of readers and to publishing communications of general interest, gives way to Information. In the new form a higher efficiency is aimed at by economy of space and a method of direct reply.

QUERY—Description of Claudel carbureter. 2—Total weight and chassis weight of 16-hp. and 20-hp. four-cylinder Sunbeam touring cars, 1915 model. 3—Meaning of term "cracking of the fuel" as found in article in THE AUTOMOBILE for Sept. 14. 4—Reason for small use of overhead camshaft of the Stutz and Mercedes type for stock car valve-in-head type engines. 5—Suitability of 2-in. clear opening valve for stock car when engine is designed to peak at 2500 r.p.m.

(1) Beemer, Neb. G. S.

—Fig. 1 is one of the latest Claudel carbureter designs. The section of the jet shows that both air and fuel are drawn through it, and in practice it is a kind of froth which leaves the nozzle. In the barrel throttle is a peculiarly shaped opening, and this acts as the choke, the area of air opening around the nozzle thus increasing as the throttle is opened. To set the "shut" position of the throttle there is a screw, and there is also a secondary fuel feed up a small pipe and past another screw which supplies a little fuel through a hole in the side of the throttle chamber. This by-pass supplies practically all the fuel for slow running, and some of the fuel all the time. Adjustment has to be made on both screws, that controlling the shut position of the throttle also affects the area of opening at all stages, it is really a choke adjustment throughout the full range, and the other screw controls the size of the by-pass orifice only.

The carbureter has to be chosen carefully to suit any particular size and sort of engine, and original adjustments are made by altering the proportions of the parts in the main nozzle, especially by varying the size and number of the little air holes in the outside sleeve of the nozzle. It is intended for gasoline.

2—The total weight of the 16-20-hp. four-cylinder Sunbeam car is between 3000 and 3400 lb. The manufacture of this car will be discontinued and the firm intends in the future to specialize on six cylinders; at least this is the latest advice from England.

3—When gasoline or kerosene is heated too strongly it breaks up into its constituent parts which consist of very light oils and very heavy ones, together with some actual solids. If cracking takes place in an intake manifold it will make tar-like deposits in the cylinders and valve chambers.

4—Because it is very expensive and it is far from easy to obtain quiet drive from an overhead camshaft. And furthermore, the overhead camshaft has no advantages for anything except racing or aviation engines.

5—This depends entirely on the size of the engine. A 2-in. clear opening is large enough for a cylinder of 4-in. bore.

? ? ?

Query—Solution for cleaning out radiator. 2—Cause of backfiring. 3—Advantage in substituting 100-amp. hr. for 80-amp. hr. storage battery.

(2) Mt. Vernon, N. Y. M. C.

—A solution of about 1 lb. of caustic soda in hot water is sufficient to fill the water system of an ordinary car. The water should be drained, the hot solution poured in, the engine run for 10 min. to thoroughly circulate the solution which should then be drained out and a continuous stream of water run in at the radiator cap and out at the drain for another 10 min. It is very important that all traces of solution should be removed, since otherwise it will damage the radiator.

2—The engine backfires, or turns in the wrong direction, when an attempt is being made to start it because the spark occurs when the piston is on the compression stroke and before it has reached the top dead center.

3—Yes. The 100-amp. hr. battery would have a longer life.

? ? ?

Query—Where to obtain equipment for wheels of Metz roadster, 1914 model, for running on railroad tracks.

(3) Glen Jean, West Va. C. P. C.

—You will have to have these wheels made specially. Probably you could make or have made rims which would clip on outside the present one. You need not be afraid to make these considerably larger than the old pneumatic tires, since, having no hills to climb, the car will bear a higher gear ratio.

? ? ?

Query—Diameter of exhaust pipe on 1915 model Fairfield Paige. Size and best position for hole for fitting cutout. Method of making hole without removing pipe. 2—Method of attachment of spotlight to windshield and wiring connections for spotlight.

(4) Newark, N. J. A. J. H.

—The diameter of the exhaust pipe on this model is 2¼ in.

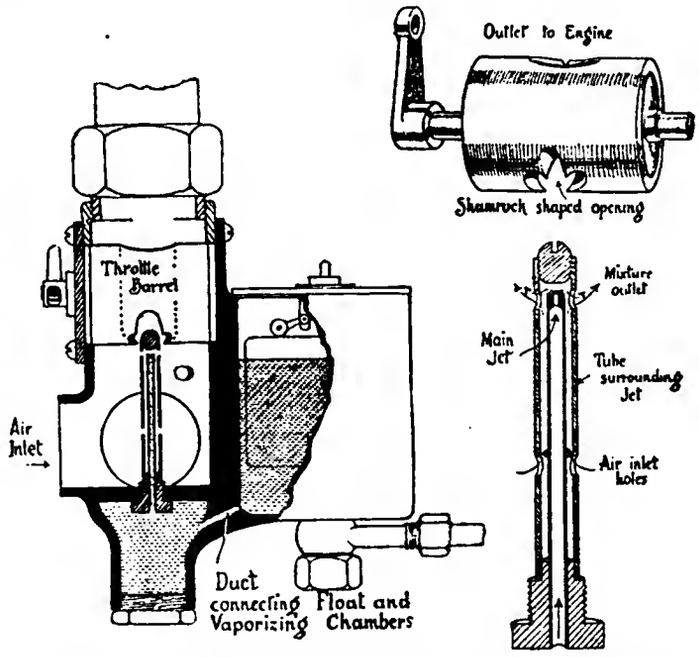


Fig. 1—Claudel carbureter of recent design, showing the action of the jet, which produces a sort of froth as the mixture leaves the nozzle

The best place to install a cutout is directly back of the bend in the pipe near the muffler. The size of the hole does not make much difference and we would suggest cutting this about 2 in. square. This can be accomplished by cutting across the pipe with a hack saw and cutting lengthwise with a cold-chisel. This is not a very easy job for an amateur unskilled in the use of a cold-chisel, but it is quite a cheap job at a repair shop.

Spotlights on the windshield are usually fitted with a plug which is attached to the dash light socket, although an extra switch can be installed on the dash and a wire run direct to the switch junction box. If the lamp should be single wire grounded type it will be necessary to run but one wire to the junction box, this to be attached to the top terminal. Should the lamp be a double wire type the two wires can be run to the top two terminals.

? ? ?

Query—Necessity for hydrogen flame in burning lead connections on batteries. 2—Possibility of using oxy-acetylene welding outfit for this work. 3—Best process. 4—Construction of hydrogen generator.

(5) Plaquemine, La. T. B.

? ? ?

—It is not essential, but it is much better to have a hydrogen flame.

2—A blow torch has to be used with great care since it is not very hot and there is a risk that too much of the lead will be heated up before it is melted at the small point where you desire to burn it. An oxy-acetylene welding outfit will give entirely too hot a flame.

3—A hydrogen generator is not a thing you can readily construct for yourself. Hydrogen is obtained in compressed form in steel bottles.

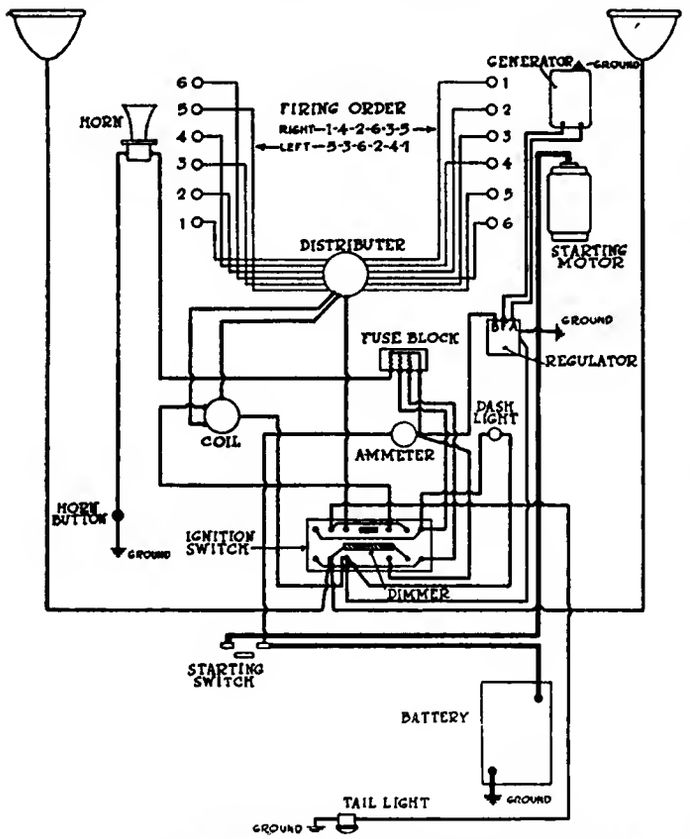

Fig. 3—Wiring diagram of starting, lighting and ignition system on the Hal car, showing connections to battery, switches, etc., and giving the firing order of the twelve cylinders

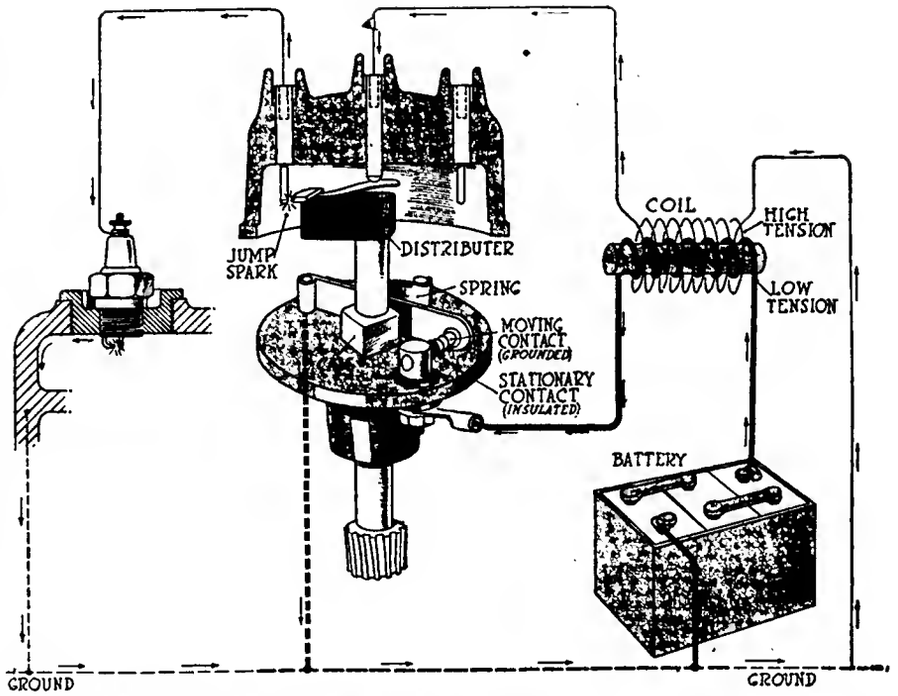

Fig. 2—Diagram illustrating the theory upon which battery ignition systems operate and showing the primary and secondary circuits

? ? ?

Query—Diagram showing theory of battery ignition systems in general, primary and secondary circuits.

(6) Brooklyn, N. Y. L. M. H.

—Diagram you request appears in Fig. 2.

? ? ?

Query—Cause of right-hand wheel of Buick model 10 locking after running about 10 ft. Brakes seem O. K., but housing gets warm. 2—Way of telling when axle is bent without taking it out of the housing. 3—Wiring diagram of starting, lighting and ignition on Hal.

(7) Bronx, N. Y. W. R. C.

—If you are certain that neither brake is binding, the axle should be taken to pieces and examined.

2—No certain way.

3—Diagram requested is illustrated in Fig. 3.

? ? ?

Query—Relative importance of the time used for combustion of the charge and of electrical lag within the ignition system in determining spark advance.

(8) Wellsboro, Pa. D. E. D.

—Spark advance is necessary almost entirely to make up for the time used in combustion. There is practically no electrical lag in modern ignition systems.

? ? ?

Query—Are steel cylinders of one piece construction with two inlet and two exhaust valves, similar to those used on the Mercedes aviation motor, made in this country?

(9) New York City. J. T.

—Several experimental engines have been built in this way, notably the Martin aviation engine in which a large number of stamped steel parts are welded together in a very ingenious way giving a cylinder with almost perfectly even thickness at every section.

Industrial Miscellany

Factory

Durston Gear Co., Syracuse, N. Y., will build a one-story, 50 by 108 ft. addition.

E. H. Sprague Mfg. Co., Omaha, Neb., has been formed to manufacture automobile accessories and is occupying the plant of the Standard Foundry Co.

Myers Rubber Co., has broken ground in Massillon, Ohio, upon which it will build a plant.

C. E. Hosbach Co., Baltimore, Md., maker of automobile tops and wagons, will build a one-story machine shop, 34 by 69 ft.

Continental Motor Truck Co., Superior, Wis., has completed work on its new factory and machine shop and is now erecting and equipping a power house.

A. Z. Metal Works, Thiensville, Wis., specializing in automobile and tractor radiators, lost its entire plant by fire. It is probable that a new factory will be erected.

Stungo-Radium Rubber Co., Pittsburgh, Pa., capitalized at $3,000,000 to manufacture automobile tires, has purchased the former Croxton Motor Co. Plant in Washington, Pa.

Piedmont Motor Co., Lynchburg, Va., is receiving bids on automobile manufacturing machinery and first installment for assembling.

National Welding Co., Newark, N. J., specializing in automobile repair work, has broken ground for a brick addition to its building. The new addition will be for the machine shop and welding department, and for handling smashed touring cars. The present building will be for commercial vehicles of every description.

Electric Tool & Appliance Co., organized recently at Milwaukee by Oscar Werwath, president of the Milwaukee School of Engineering, will erect a plant in the spring for the manufacture of patent box cutters and scientific laboratory apparatus. Temporary quarters will be obtained at once.

Aluminum Goods Mfg Co., Manitowoc, Wis., has purchased a group insurance policy in the Aetna Life covering all employes of the three big plants, at Manitowoc and Two Rivers, Wis., and New ark, N. J. The policy amounts to about $1,000,000 and the maximum sum on each employe is $1,000. It was purchased as a Christmas gift for employes.

General Bakelite Co., New York, has moved to 2 Rector Street. This company produces Bakelite, the heat-resisting, molded insulation.

Willys-Overland Co., Toledo, will establish a factory branch in Winnipeg, Man., to be a distributing point for the Province of Manitoba. This is the third branch to be opened by this company, the others being in Montreal and Regina.

Iowa Rubber Tire Co., has purchased the plant of the American Can Co., Davenport, Ill., for $70,000.

Reliable Auto Heater Co., Cleveland, has leased a plant formerly occupied by the Ashtabula Mfg. Co., on east side of city. This plant will be known as the Vesuvian Auto Heater Works. S. T. Campbell is in charge at this plant.

Stegeman Motor Car Co., Milwaukee, a manufacturer of trucks, will build a factory addition, 79 by 190 feet, adjoining the present plant at Woodworth and Linus Streets. The building will be of fireproof construction, and cost about $50,000 complete. It will be devoted principally for assembling purposes, and the space thus released from the present shops will be equipped with machinery and tools to provide the new shop with a largely increased output of parts.

The Automobile Calendar

ASSOCIATIONS

Progressive Dealers Know It Pays to Sell Leaders Only

Live dealers everywhere—men who do a big business and are making big money—know by experience that it pays to sell *Leaders Only*. They stock, sell and feature Stewart Products. The wide demand for Stewart Products is extremely significant to the wise dealer. It points out to him the unmistakable trend of public opinion—the tremendous demand for the best known and most widely advertised automobile accessories on the market.

The dealer who has achieved really big success does not waste his time, energy and money in trying to "put across" unknown accessories. He banks on a steady, consistent "turnover." He handles the one established line—the one that is universally accepted as standard. He carries a complete stock of Stewart Products.

Stewart Products offer you a steady source of income all year 'round—not only in Summer, but also in Winter, when you need it most. Determine right now to sell nothing but Leaders. Concentrate on, "boost," feature and sell Stewart Products—the fastest-selling and easiest-to-sell of all automobile accessories.

$1,900,000 for Buick Additions

Pres. Chrysler Receives Funds from General Motors Co. for Expansion

Flint, Mich., Dec. 27—The General Motors Co. has turned $1,900,000 over to W. P. Chrysler, president of the Buick Motor Co., to provide for expansion of the Buick manufacturing facilities, the method of investment being left to Mr. Chrysler's discretion. Plans for a new office building for the company to cost $225,000 are under way.

—

Lewis Goodyear Consulting Chemist

Boston, Dec. 26—Dr. Warren K. Lewis, professor of chemical engineering at the Massachusetts Institute of Technology, has been appointed consulting chemist for the Goodyear Tire & Rubber Co.

—

Form Britton Carburetor Mfg. Co.

Cleveland, Dec. 26—The Britton Carburetor Mfg. Co., this city, has been incorporated with a capital of $50,000, to manufacture carbureters. The incorporators are L. M. Diehl, A. C. Diehl, P. C. Jobes, C. F. Schultz and G. C. Middleton.

—

Dayton Wire Wheel Co. Formed

Dayton, Ohio, Dec. 26—The Dayton Wire Wheel Co., this city has been incorporated with a capital of $250,000, to manufacture wire wheels for automobiles. The incorporators are A. N. Wilcox, L. H. Roggs, L. W. James, J. B. Coolidge and B. D. Moore.

—

Bonus for Employees

Detroit, Dec. 26—The General Aluminum & Brass Mfg. Co. will pay a service bonus for the year ending Dec. 1, 1916, to all employees who are not stockholders. Under the plan adopted, employees who have been in the service of the company for 4 years or longer will receive 10 per cent of their wages for the year. Those with 3 years of service will receive 7½ per cent of their annual pay. Those with 2 years get 5 per cent. Those with 1 year's service secure 2½ per cent, and those with less than 1 year's service will receive one-half of 1 per cent.

—

Causan, French Engineer, Joins Chalmers

Detroit, Dec. 27—Nemorin Causan of the Paris branch has joined the engineering staff of the Chalmers Motor Co. Mr. Causan, who has been investigating automobile conditions in Detroit for the past 7 months, was formerly connected with Delage, Bayard-Clement and Panhard & Levassor and was the designer of several victorious French racing cars.

—

A New Scripps-Booth Four

Detroit, Dec. 27—In line with new models to be shown at the coming New York show will be the new four-cylinder Scripps-Booth, just announced. This car will be known as Model G and will have a 3 11/16 by 4-in. Brush design of overhead-valve engine. Other features will include a Zenith carbureter, Remy 6-volt lighting and starting, a cone clutch, 30 by 3½-in. wheels, semi-elliptic front springs with cantilever springs on the rear.

There will be two body types, a three-passenger roadster selling at $930, and a coupé at $1,450. Both will have wheelbases of 110 in.

—

Chamberlain Heads Packard Truck Sales

Detroit, Dec. 26—R. E. Chamberlain, truck sales manager of the Packard Motor Car Co. of New York, has been promoted to the position of truck sales manager of the Packard Motor Car Co. of Detroit.

India Bars Motor Imports

All Vehicles Using Gasoline Are Affected—Gasoline Shortage Is Acute

New York, Dec. 27—The gasoline shortage in India has become so serious that the government there has prohibited for an indefinite time the importation of automobiles, trucks, motorcycles, and all vehicles using gasoline, according to cable dispatches received by Dodge & Seymour, Ltd., export merchants of this city, handling the Ford and Hudson in British India and the Orient. According to the ruling no shipment will be permitted to enter India which has left the United States after Jan. 1, 1917. On top of this announcement comes a further increase of 1 cent in the price of gasoline for export.

India has been a good buyer of automobiles, averaging 400 to 500 a month. There are at present about 20,000 cars there. Automobiles coming into that country are taxed 7½ per cent.

—

Hayes Mfg. Capital $1,750,000

Detroit, Dec. 27—Hayes Mfg. Co. stockholders have voted to increase the capital of the company to $1,750,000. The plan calls for 75 per cent stock dividends. Common stock worth $625,000 will be placed on the market.

—

Muskegon Company Insures Employees

Muskegon, Mich., Dec. 26—The Muskegon Motor Specialties Co. for a Christmas gift gave its employees, numbering 300 men, insurance policies ranging from $500 to $1,000, depending on the length of service. The policies are effective as long as the men stay with the concern.

Hall Lamp Co. Buys Badger

Has Option on Brass Co., Maker of Solar Lamps—Late News By Wire

KENOSHA, WIS., Dec. 27—The C. M. Hall Lamp Co. of Detroit has an option for the purchase of the Badger Brass Mfg. Co., this city, and is completing details of the purchase this week. The Badger concern has been well known throughout the industry since its inception as manufacturer of Solar lamps.

Late News Over the Wire

DETROIT, Dec. 27—B. F. Kenyon, who has maintained a hangar in Muskegon, Mich., for the past year, will erect a factory there to make aeroplanes for government mail service.

Many large gasoline distributers in Detroit are suffering from a famine of gasoline because of freight congestion. Prices have advanced 2 to 3 cents, and many gasoline stations have shut down entirely.

The Dort Motor Car Co., Flint, gave each of its employees $600 toward an insurance fund for Christmas.

Business of the Ohio Electric Car Co., Toledo, was 40 per cent higher in December than last year, and the company is adding all the workers it can get.

G. E. Willis, Russian representative of the Studebaker Corp., returned this week from Petrograd.

Packard, Buick and Chevrolet plants are taking inventory and are closed until Jan. 2.

Reynolds, of Studebaker, Dead

DETROIT, Dec. 26—C. J. Reynolds, purchasing agent for the Studebaker Corp., died suddenly at his home last Sunday. Mr. Reynolds was connected with Studebaker for the past 30 years.

Falcon a Four-Wheel Drive

MEMPHIS, TENN., Dec. 23—Automobiles with a four-wheel drive will be manufactured in this city by the Falcon Motor Car Co., recently formed with a capital of $150,000 by local business men. The car will be assembled. The company is composed of J. G. Hamblett, E. E. Karlson, J. R. Manley, G. A. McGill and C. F. Kessler.

Peerless Tire & Rubber Co. Formed

GREEN BAY, WIS., Dec. 23—The Peerless Tire & Rubber Co., which has been incorporated here by F. E. Burrell, J. T. Jessen and A. W. Brown, all of Green Bay, who now are operating a factory in the Ohio rubber district. The company is capitalized at $50,000. It owns the molds and controls the output of the existing plant. The product is being marketed from Green Bay at this time and as soon as practicable it is planned to transfer manufacturing operations from Ohio to Wisconsin.

255,000 Cars Registered in Ohio

COLUMBUS, OHIO, Dec. 23—There are over 255,000 automobiles in Ohio, or more than double the number 2 years ago. It is predicted there will be over 300,000 next year.

300,000 1917 Registrations for N. J.

TRENTON, N. J., Dec. 23—It is estimated that 300,000 automobile licenses will be given in this state in 1917. Beginning Jan. 1, uniform drivers' licenses, costing $3, will be issued, and 3-week permits for beginners, heretofore free, will cost 50 cents.

115,645 Cars in Wisconsin

MILWAUKEE, Dec. 23—Wisconsin registration for 1916 numbers 115,645 cars. The final issue of 1916 licenses was made on Dec. 15, on which date the first applications for 1917 licenses were accepted. The total registration in 1915 was 79,791. showing that Wisconsin absorbed 35,854 cars during the present year. A. J. Cobban, in charge of motor registry in the office of the Secretary of State, estimates an issue of at least 150,000 licenses in 1917.

198,050 Cars in Iowa

DES MOINES, IOWA, Dec. 26—At the close of automobile registrations in Iowa for 1916 the total for the year stood at 198,050 with the total of fees collected at $1,854,501. The increase in the number of cars registered as compared with 1915 is 52,942 and the increase in fees collected is $321,448. A table showing the number of cars registered and the fees collected since 1911 follows:

1911	27,988	$259,736
1912	44,188	485,300
1913	70,068	646,468
1914	106,087	1,040,135
1915	145,109	1,533,053
1916	198,050	1,854,501

Luverne to Expand

LUVERNE, IND., Dec. 26—The Luverne Automobile Co., this city, is enlarging its operations, and in connection with such enlargement it is offering an issue of $50,000 6 per cent cumulative and participating preferred stock.

Shuger Resigns from Auburn

AUBURN, IND., Dec. 23—J. Frank Shuger has resigned as superintendent of the Auburn Automobile Co., after filling that office for 12 years. Mr. Shuger has announced no plans for the future.

Three More Price Increases

Hal, Briscoe and Regal Companies Add to List Prices for 1917 Models

CLEVELAND, Dec. 26—All models of the Hal twelve will be increased in price, effective Jan. 1, 1917. The touring and roadster models will increase from $2,385 to $2,600, the Springfield touring sedan from $3,250 to $3,500, and the Westchester limousine and brougham models from $4,250 to $4,500.

Briscoe Increases Price $60

DETROIT, Dec. 26—The Briscoe Motor Corp. has increased the price of the model 4-24 $60 to $685, effective Jan. 1.

Regal Price Raised $50

DETROIT, Dec. 27—The Regal Motor Car Co. has increased its car price $50, the old price being $695.

Duplex Acquires Plant Site

DETROIT, Dec. 21—The Duplex Motor Truck Co., of Lansing has purchased 15 acres of land on which work will immediately begin for the construction of a plant, 60 ft. by 800 ft. The plans are for a daily production of ten trucks. The new factory will employ 250 men. More than $50,000 worth of new machinery has been ordered which will be used to enlarge the plant that is to be moved from Charlotte.

Oregon Has Car to Every 25 People

PORTLAND, ORE., Dec. 23—The State of Oregon now houses one automobile for every group of twenty-five residents, as compared with one car for every thirty-three people a year ago.

The total registration for the 1916 series is 33,908. For the 1915 series there were only 23,585 cars, the gain for this year being more than 10,000 cars, or 44 per cent.

Day-Elder Motors Corp. Incorporates

NEWARK, N. J., Dec. 26—The Day-Elder Motors Corp., this city, maker of trucks, has incorporated for $1,000,000. The incorporators are C. P. Day, F. G. Elder, and Theo. McMarsh.

Working on Low Fuel Carbureter

DETROIT, Dec. 23—P. S. Tice, formerly chief engineer of the Holly Carbureter Co., is working with F. E. Watts, chief engineer of the Hupp company, developing a carburetion unit for low gravity fuel.

U. S. A. Cars Gain in Argentina

Cadillac Agent in Buenos Aires, Here for Show, Tells of Conditions

NEW YORK, Dec. 26—Albert Fehling of Fehling Bros., Buenos Aires, Argentina, who has been Cadillac agent in Argentina for 14 years, and who has handled the Jeffery line for the past year, arrived in this city Saturday for the purpose of visiting the automobile show as well as factories. Mr. Fehling advises that the demand for U. S. A. automobiles has increased. He is searching for town car bodies which previous to the war Buenos Aires dealers purchased in Europe. In Argentina, where Latin customs prevail, the sedan or coupé types are not in use at all. The business man and members of his family refuse to sit in the same compartment with the chauffeur. Consequently closed types are restricted to limousines and town cars, with a few landaulets. The majority of those using limousines and town cars prefer that passengers occupying the auxiliary seats face forward instead of backward. This seating arrangement calls for a slightly larger closed compartment than where the passengers on the auxiliary seats face the rear.

Mr. Fehling advises that the selling season in Argentina is now at its height and that owing to the very dry season roads throughout the country which are at best in an unimproved condition, have been better this year than in many seasons, a fact which has visibly accelerated the sale of cars. Unfortunately, owing to the dry weather, cable dispatches this week from Buenos Aires place the wheat crop of the country at 50 per cent that of a year ago. This should have a serious effect on the sale of cars unless prices are proportionately higher.

Wide Treads Essential

The sale of automobiles with 56-in. treads is practically limited to the city of Buenos Aires. In the country, or camp, owing to bad roads the 60 or 62-in. tread is imperative. He accounts for the greatly increased sale of several U. S. A. cars to the fact that they have wide treads and Mr. Fehling thinks it practically impossible to sell cars with 56-in. treads in the country districts. Several makes of U. S. A. cars at present in Argentina with 56-in. treads are not selling. The wide tread and 10-in. clearance are essential. Right-hand steering is also essential.

Mr. Fehling is of the opinion that owing to the great difference in price between touring bodies and closed bodies in U. S. A. that it will be necessary for Buenos Aires dealers to begin the manufacture of their own closed types. He states that previous to the war the difference in price between an open body and closed body built in Europe was only 50 per cent of the present difference between open and closed bodies in U. S. A. The greatly added cost of closed types will make it practically prohibitive for the Argentine dealer to import our closed style.

Owing to the winter season coming in the months of May, June, July and August in Argentina, the closed car business alternates with that in this country. This should make it favorable for the purchase of closed cars in New York. It would call for deliveries in Buenos Aires May 1, and for a month or 6 weeks thereafter. Owing to this difference in seasons, it would be possible for U. S. A. builders to seriously consider South American closed-car trade.

—

Ford Victor in Appeals

DETROIT, Dec. 23—The supreme court of Michigan denied the petition of John F. and Horace Dodge for the further extension of the injunction against the expenditure by Henry Ford of the accumulated cash dividends, and shortly afterward, yesterday afternoon, granted Mr. Ford's petition asking that he be permitted to continue the execution of the contracts for the River Rouge smelting plant on condition that he file a bond protecting Dodge Brothers from possible loss.

—

Ford Appeals to High Court

DETROIT, Dec. 21—Henry Ford's attorneys will file petitions with the supreme court at Lansing which will bring the injunction issued in favor of Dodge Bros., in their suit against Ford, before the highest court in the State for review.

—

Ford Wins Windshield Case

NEW YORK, Dec. 23—The Ford Motor Co. has won a decision against the Stahlbrodt Co., Rochester, N. Y., holder of a patent purporting to cover a certain type of windshield commonly known as the "zig-zag windshield," in the United States circuit court of appeals for the second district, in this city.

The decision reverses a prior ruling of a lower court. The shield in question is that in which the lower half inclines rearwardly while the upper half is vertical. It is no longer used on the Ford.

—

Reo Working Force Is 5000

LANSING, MICH., Dec. 27—The Reo Motor Car Co. working force now numbers 5000, 1500 more men being employed than in the summer of 1915. The company is shipping 100 cars a day on flat cars because of freight congestion.

P. O. Fraud Order Against I. A. L.

—

Supplemental Order to That of Aug. 2 Bars League Men from Mails

WASHINGTON, Dec. 23—The Postoffice department has issued a fraud order against the International Automobile League, the International Automobile League, Inc., and A. C. Bidwell, president, in the form of a supplemental order to that issued Aug. 2, 1916, under which latter order the Postmaster of Buffalo is instructed not to deliver to 637 Main Street, that city, any mail addressed as above except mail under the frank of a member of Congress or mail matter not under seal. The order also covers the payment of money orders addressed to the above.

In issuing the order the Solicitor of the Department suggests that the names against the fraud order is issued seem to have been adopted by Bidwell for the sole purpose of avoiding the effect of the fraud orders issued against his business last Aug. 2. The order also states that Bidwell has been sending out postcards under the new name as a result of which he seeks to collect alleged past dues for membership in the organization.

—

Disco Corporation Plans Expansion

DETROIT, Dec. 26—The Disco Electric Starter Corp. will occupy a new building in January and plans to produce starters on a vast scale, the 1917 output being practically sold at this time.

—

Disco Creditors Meet

DETROIT, Dec. 23—Creditors of the Disco company had their final meeting before the United States court, here, yesterday to receive the last report of the Security Trust Co., trustee. Within the next 30 days, the trust company will distribute the remaining assets in a payment of about 2 per cent. This combined with the two earlier payments of 10 per cent and 12½ per cent will give the creditors about 25 cents on the dollar.

—

Parker Rust-Proof Factory at Flint

FLINT, MICH., Dec. 26—The Parker Rust-Proof Co. of Detroit will build a branch factory in this city. The company plans to erect twenty-five branch plants in the leading metal cities of the United States.

—

Western Motor Appliance Moves

DETROIT, Dec. 26—The Western Motor Appliance Co. of Charles City, Iowa, will move its plant to Alma, Mich.

Sweden Has Only 9000 Cars

Fisk Tire Representative from Stockholm Says Poor Roads Hamper Car Sales

NEW YORK, Dec. 26—Sweden will be represented at the New York automobile show by at least one, and perhaps by several automobile and accessory dealers. Hans Osterman of Stockholm, who has sold Minerva cars for 6 years, has been in this country some weeks and will remain until the close of the show circuit. In addition to selling the Minerva in all Sweden since 1908, he has handled a line of tires and accessories, being at present Swedish representative for Fisk tires.

Although Sweden is a little larger in area than Germany, it has a population of only 6,000,000, approximately the same as Australia, and just a little more than half as large as Canada or Argentina. Mr. Osterman estimates that in all Sweden there are approximately 9000 cars, of which number 3000 are in the city of Stockholm. This city has 350,000 population.

At present many of the cheaper makes of U. S. A. cars are represented in Stockholm, and have been sold for years. The bad condition of roads has held back considerably the sale of cars, which has largely been confined to the cities. Up to the present the farming community has not purchased cars and it is doubtful if the farmers will ever be a purchasing factor as in this country. In Sweden farms are smaller.

Centers at Stockholm

The automobile industry of Sweden largely centers in Stockholm where there are thirty dealers, eight of whom are important, and maintain salesrooms similar to those in any American city of corresponding population. Stockholm has not its automobile row as in many of our American cities, but the dealers are now locating in the best quarter of the city. In addition to these dealers there are perhaps fifty garages, some of which have capacity for sixty cars. In the large garages each car is kept in a separate stall as in South American cities. Practically all of the cars in Stockholm are driven by chauffeurs, but the simplifying of cars by electric starters, electric lighting, etc., is already having its influence and private owners and women are taking up driving.

The average car owner in Stockholm has one chassis and two bodies, a summer body and a winter body. The winters in Stockholm are much the same as in New York, but further north the weather gets very cold and in the most northerly points there is winter for several months of the year. In Stockholm are six good body builders who handle much of the closed car trade. Bodies are, however, more expensive than those that were procured from Belgium, France and England previous to the war.

As with all European countries, Sweden has suffered greatly because of the war. Her chief difficulty has been in securing pneumatic tires and tubes which have all had to come through London. As a result of the tire restrictions over one-half of the taxicabs are out of commission and a good percentage of private cars are in storage. Many cars have been operated for several months with the worn-out casings filled with rags. It is expected that for 1917 tire restrictions will be somewhat relieved.

Since the war U. S. A. cars have been about the only ones reaching Sweden. To these might be added a very few German machines. At present ten different makes of U. S. A. cars are entering the country.

Sweden exists practically as a consumer market for automobiles, her status as an automobile manufacturing country being limited to two makes of Swedish cars. One of these is manufactured in quantities of approximately 300 per year. It is made in two models selling at approximately $2,500 and $3,500 each. The car is known as the Scania Vabis. It is manufactured almost entirely in the factory. The other manufacturer produces motor trucks in very small quantities.

Mechanics Plentiful

The automobile industry in Sweden is blessed with plenty of good mechanics. The Swedes are mechanically inclined, and the fact that much good machinery is manufactured in the country has had its influence on developing the mechanical phase of the people.

The importation of cars into Sweden is not seriously hampered by prohibitive custom duties. Automobiles are assessed 15 per cent on the value at the port of entry. This includes freight which at present amounts to $500 to $600 per car.

Tires are taxed at the rate of approximately 35 cents per kilo weight. A kilo is 2 1/5 lb.

There are various custom schedules for accessories: For example, magnetos are assessed 15 per cent of their value. On brass lamps the rate is 12 cents per kilo; on lamps with a nickel finish 20 cents per kilo; and on brass lamps which are enameled 20 cents per kilo. These figures are sufficient to show the general scope of custom duties.

Fine Touring Country

As a country for the use of automobiles Sweden is best described as being hilly, and consequently favored with fine natural beauty attractive to the motorist. The country is well served with macadam roads which wind and twist through the mountain districts as well as the agricultural sections. It is possible to go north from Stockholm approximately 600 miles on good roads. Very satisfactory hotels are found through the entire country. It is possible on a day's drive to average 25 m.p.h. for much of the time. This means hard driving. Up to the present the speed law has been 10 m.p.h., but beginning with Jan. 1, 1917, the legal limit has been raised to 25. It costs approximately $9 to register an automobile in Sweden. This is not an annual registration, but a continuous one, the registration going with the car and not the owner.

Continental Service Stations

To Help Users of Its Engines With Service in Principal Cities

DETROIT, Dec. 27 — The Continental Motors Co., this city and Muskegon, will establish service stations in all of the principal cities in the United States. The company has closed large contracts in both New York and California for the first of the service stations. While the details have not been disclosed, an official of the company states that the plan includes not only the policy of serving the owner but also the manufacturer in solving his service problems.

A special meeting of the stockholders of the company will be held Dec. 30 for the purpose of acting upon the proposal to sell the assets, business and good-will of the company to the new proposed corporation to be formed under the reorganization plan.

Jennings Becomes Advertising Mgr.

BOUND BROOK, N. J., Dec. 22—W. F. Jennings has become eastern sales and advertising manager of the Bound Brook Oil-less Bearing Co., this city. He has been connected with this company for nearly 3 years.

Latour with Chalmers Advertising

DETROIT, Dec. 27—J. F. A. Latour has joined the advertising staff of the Chalmers Motor Co. Mr. Latour was formerly connected with *The Evening Ledger* of Philadelphia.

Collins Joins Harroun Staff

DETROIT, Dec. 26—J. F. Collins has joined the staff of the Harroun Motors Corp. Mr. Collins was formerly the cost and system expert for the Cadillac company.

Ask Forfeiture of Charter

State Authorities File Suit Against All-Steel Co. After Investigation

ST. LOUIS, MO., Dec. 23—The State Attorney General's Department yesterday filed suit in the Circuit Court at Macon, Mo., to forfeit the charter of the All-Steel Motor Car Co. This action was taken after an investigation of A. L. McCawley, head of the corporation department of the office of the Secretary of State. This company recently has been conducting an energetic stock selling campaign here, much of their advertising being done under the name of the Macon Motor Car Co., which name it was explained that the company would take at its annual meeting.

The night before the suit, McCawley met and addressed a mass meeting of those who recently have bought stock and explained that they could reorganize under the name they wished and that the suit would not impair the value of the assets. The suit, he said, was necessary because of irregularities in the actions of the All-Steel Motor Car Co. affairs. He charged that:

Patents of Doubtful Value

The All-Steel company, when organized for $400,000 capital, half paid in, had filed a statement that $5,000 of this was cash and $195,000 in value of patents on a combined body and chassis and device for transmitting power to wheels. He said the company never had $5,000 and the patents had lapsed and were of doubtful value.

The company, he said, removed from St. Louis to Macon without notice.

The change of the record to show 40,000 shares of $10 each instead of 4000 at $100 each, he said, was without notice to his office.

That no explanation had been made of the return of $100,000 worth of stock by C. L. Smith, the inventor, had never been explained.

After hearing these charges and receiving assurance that the present stockholders could retain the real estate, worth including a former buggy factory building, $275,000, practically a present from the citizens of Macon, and that the money already advanced for parts of cars to be assembled for next season's selling, the stockholders voted to reorganize at once.

The present officers of the company are Macon business men, who practically took over the All-Steel company when they believed that it was going to collapse. They have provided the present assets in an endeavor to build up an industry for the town to take the place of the buggy factory. A stock selling office has been maintained at 707 Olive Street, this city, for several weeks and a car of the type that is to be assembled at the plant is on display there. How many of the 40,000 shares at $10 each have been sold is not made public but the end of the campaign is not yet. It is said that later an effort will be made to sell stock to the value of $1,000,000. The company has been making purchases of assembly plant material and of some parts here within the last few weeks and is reported to have paid cash on such purchases.

The present officers and promoters have made no pretense that they expected to use the Smith patents, asserting that the departure for a combined body and chassis and for transmission of power to wheels was too radical an innovation for them to undertake. C. L. Smith, who promoted the all-steel patents, participated in the stockholders' meeting.

—

Morron Succeeds Meyer

NEW YORK, Dec. 22—J. R. Morron has been elected a director and member of the executive committee of the Maxwell Motor Co., Detroit, to fill the vacancy caused by the resignation of Eugene Meyer, Jr.

J. C. Brady was elected chairman of the board, and of the executive committee in the place of J. C. Jay, Jr. Mr. Jay will continue as a director of the company, and has been elected a vice-president.

Mr. Morron is president and a director of the Atlas Portland Cement Co., and is also a director in the following companies: Baltimore & Ohio Railroad, Chicago, Great Western Railroad, Guarantee Trust Co., the American Surety Co., and the National Bank of the Republic of Chicago.

—

Steele Succeeds Barber

MOLINE, ILL., Dec. 23—M. A. Steele has become sales manager of the automobile department of the Moline Plow Co., maker of the Stephens car. He succeeds A. C. Barber. Mr. Steele has been connected with the company for several years. He was formerly manager of the Stephens Six factory, where he is succeeded by H. J. Leonard, who assisted him.

B. F. Durham has become associated with the company as assistant sales manager.

—

Williams Goes to Antipodes

DETROIT, Dec. 23—E. F. Williams, special foreign representative for Dodge Brothers, will leave shortly for Manila, Australia and New Zealand.

$170,000,000 in Overlands

Dealers Contract for Cars to That Value—Co. Has Abundant Material

TOLEDO, Dec. 22—The final group of Willys-Overland dealers to visit that company's factory during the convention added approximately $10,000,000 worth of contracts for cars, bringing the total value of cars ordered during the convention up to $170,000,000. The company built 96,000 cars in the first 6 months of 1916.

John N. Willys, president of the concern, addressed the guests and stated that the shipping facilities of Toledo would be a boon to the company in 1917 and that the company has $30,000,000 worth of raw material on hand, including more aluminum than any other manufacturing concern in the world. A silver loving cup was given to Mr. Willys by Mayor Joseph Bell of Indianapolis as a token from the Gibson Raiders, the salesmen from Indiana and Illinois.

—

Gardner, of Chevrolet, to Retire

ST. LOUIS, MO., Dec. 23—Russell E. Gardner, president of the Chevrolet Motor Co. of St. Louis, a manufacturing branch of the larger Chevrolet company, will retire from business after the first of the year. He will turn his large plant over to his sons, R. E. Gardner, Jr., and Fred Gardner. Mr. Gardner, who is rated at several millions, came to St. Louis from Tennessee 37 years ago without means. He began at the bottom in the buggy business and later acquired complete ownership of the Banner Buggy Co. and as the business began to fail he absorbed several other plants. It was this equipment that he made the basis of the organization of the Chevrolet Motor Co. of St. Louis.

—

D. A. C. Honors Hugh Chalmers

DETROIT, Dec. 22—A banquet was held last night by directors of the Detroit Automobile Club as a token of friendship and mark of gratitude for the work of Hugh Chalmers as director of the organization. Mr. Chalmers will retire from the presidency of the D. A. C. on Jan. 1.

—

Christiansen Goes to Detroit

NEW HAVEN, CONN., Dec. 22—E. S. Christiansen will become manager of the Detroit office of the United Smelting & Aluminum Co., this city. He was formerly purchasing agent. W. T. Schmitt, formerly of the Bosch Magneto Co., has been appointed assistant manager at the Detroit office.

56,539 Fords in October

Schedule for 1917 Calls for 750,000—Average Selling Price $400

DETROIT, Dec. 23—The Ford Motor Co. produced 56,539 cars in October, which is almost equal to the highest month, March, in which 58,394 cars were made. The scheduled output for the current fiscal year is 750,000 cars, as against actual production of 523,920 in the 1916 year and 308,213 in the 1915 year.

The average selling price of the Ford product for the past year was a trifle over $400, gross business amounting to $206,867,000 and cars sold totaling 508,000. With the present $80 reduction on Ford cars, the total gross business for the current fiscal year should be approximately $240,000,000.

Ford Plant Closes for Week

DETROIT, Dec. 21—The Ford Motor Co. will close its plant for the entire week between Dec. 22 and Jan. 3 to aid the railroads to move food and fuel shipments.

F. L. Klingensmith, vice-president of the company states that the officials of the concern do not believe it to be right for the company to use railroads for shipment of cars when the various communities are threatened by famine because of railroad congestion. The suspension means a production loss of 175,000 cars for the week and affects 42,000 workers who will suffer a wage loss of $200,000 a day or $1,400,000 for the week.

The plant will also allow the steel mills which are now far behind on orders to catch up to some extent.

No work will be done during the suspension and no cars will be shipped or coal used except as is necessary to keep the plant just above the freezing point. An attempt will be made later to catch up in production though no plans have been formulated as yet. Officials of the company state that there is plenty of material on hand, that cars are being sold more quickly than they can be made and that the reason for closing is purely a humane one.

Holland Joins Myers Machine

SHEBOYGAN, WIS., Dec. 23—H. F. Holland, Indianapolis, Ind., has been appointed sales manager of the motor truck division of the Myers Machine Co., Sheboygan, Wis., to succeed L. P. Helm, resigned. The Myers company absorbed the Wisconsin Motor Truck Co., Baraboo, Wis., early this year, purchasing the interests of Mr. Helm, who joined the Myers company as manager of the truck department.

Pontiac Tractor Co. Formed

Hubbard, Welsh and Wright Behind Co.—To Sell at $750

DETROIT, Dec. 21—The Pontiac Tractor Co. has been incorporated for $42,000 in this state and will take over the Wright Mfg. Co. plant at Pontiac for the manufacture of a tractor to sell at $750. The officials of the new concern will include M. D. Hubbard, of the Hubbard Spring Co.; Fred S. Welsh, who was at one time connected with the Welsh Motor Car Co., which is no longer in existence, and N. A. Wright, of the Wright Mfg. Co. The tractor has been tried out during the past year and was found to be successful, according to officers of the concern. It is constructed with a steel frame, and a single-cylinder oil-burning engine of 30 to 35 hp. The complete tractor weighs 4200 lb. The company plans to produce from three to five tractors per day.

Four Dort Models for 1917

FLINT, MICH., Dec. 23—The Dort Motor Car Co., this city, is now manufacturing four models, a five-passenger sedan at $1,065, a sedanet with a permanent top but detachable if required at $815, a five-passenger touring car at $695, and the Fleur-de-lys three passenger roadster at $695. All these models are on the same chassis. The sedan, however, carries 31 by 4 tires instead of 30 by 3½, the standard size for all the other models.

Scofield Is Drexel Sales Manager

DETROIT, Dec. 26—H. H. Scofield has joined the Drexel Motor Car Co. as director of sales. He has been connected with the Acme White Lead and Color Works, this city, the Studebaker Corp., General Motors Co. and the Paige-Detroit Motor Car Co. He will have full charge of sales and supervision over advertising and service.

Pearce Elected President

ASHTABULA, OHIO, Dec. 22—A. E. Pearce has been elected president of the Pearce Tire & Rubber Co., succeeding J. L. Smith, resigned. H. J. Atwood was elected secretary-treasurer in place of P. C. Remick, resigned. The following directors remain on the board: A. E. Pearce, H. J. Atwood, J. L. Smith and F. L. Kerr. A. W. Green resigned from the board.

Victor Buys Jenkintown Factory

PHILADELPHIA, Dec. 23—The Victor Motor Co., this city, has purchased the property of the Jenkintown Switch and

Signal Co., north of Philadelphia, where it is planned to make the Victor four. The property includes 25 acres of land and nine buildings owned by the former concern. The cost of the property is $92,000 to be paid within a year. The location previously selected at Grubbs Landing, Del., has been abandoned. C. V. Stahl, vice-president of the company and inventor of the Victor engine, said the company has an order for 5000 cars as soon as completed, out of which fifty are to be shipped to a firm in Norway.

—

Economy and Bellefontaine Merge

BELLEFONTAINE, OHIO, Dec. 22—The Economy Motor Car Co., of Tiffin, Ohio, and the Bellefontaine Automobile Co., of Bellefontaine, plan to merge and will locate their combined factory in this city.

—

Blagden American Malleables President

LANCASTER, N. Y., Dec. 22—A. S. Blagden has been elected president of the American Malleables Co., this city, succeeding W. G. Pearce, who has been made chairman of the board. This company specializes in malleable iron automobile castings.

—

Langerbacher With Duplex Truck

DETROIT, Dec. 21—Andrew Langerbacher has become sales manager of the Duplex Truck Co., of Lansing. Mr. Langerbacher was formerly with the sales organization of the Reo Motor Car Co.

—

Gerlinger Builds Six-Cylinder Truck

TACOMA, WASH., Dec. 23—The Gerlinger Motor Car Co., this city, is building a ton and a half, six-cylinder, self-starting and electric-lighted truck that will be ready for delivery Feb. 1, 1917.

—

Detroiter Convertible Coupé and Sedan

DETROIT, Dec. 26—The Detroiter Motor Car Co., this city, has brought out a convertible coupé and sedan, selling at $1,398 and $1,373, respectively.

Paterson Chummy Roadster

New Model Added to Line—Bodies Improved for 1917—Few Changes

FLINT, MICH., Dec. 19—The W. A. Paterson Co. is continuing its six-cylinder chassis without change for 1917. In addition to the touring body, however, a chummy roadster has been added and a number of refinements are incorporated in both.

The movements in the 1917 touring car are principally in the way of providing more room in the body. The lines are longer and wider, giving a greater amount of room. The front seat is 41 in. wide by 18 in. deep. The rear seat is 48 in. wide by 20 in. deep. This is about 5 per cent increase in seating area.

Four passengers are seated in the new roadster, which is on the same chassis of 117 in. wheelbase. The two front seats in the roadster are 17 in. wide by 16¾ in. deep and the rear seat is 36 in. wide by 16¾ in. deep. This is a clover-leaf layout.

The Paterson chassis has a six-cylinder Continental engine, Delco electrical equipment, Willard battery, Stewart vacuum feed, Stromberg carbureter, Goodrich tires, and one-man top.

—

Pfeffer Returns from Cuba

DETROIT, Dec. 21—C. A. Pfeffer, formerly vice-president and assistant general manager of the Chalmers Motor Co. has returned from his visit to Cuba.

—

Spohn Leaves Class Journal to Join U. S. Ball Bearing Co.

CHICAGO, Dec. 26—Howard L. Spohn, for the past 8 years with the Class Journal Co., has become commercial manager of the U. S. Ball Bearing Co. of this city Jan. 1. The entrance of Mr. Spohn into this corporation in no wise infers any changes in the organization but is due to anticipated enlargement of manufacturing facilities and the acquiring of additional allied interests.

Walter H. Strom remains as secretary and general manager with an augmented factory organization including S. W. Brandel, factory manager; M. Zelinski, superintendent in charge of production; H. N. Corsline, shop engineer in charge of inspection; W. E. Hutchinson, purchasing manager, and A. L. Moyel, office manager. E. B. Fleisch continues as sales manager, with K. I. Fosdick remaining as western representative.

—

Chandler Increases Wages 10 Per Cent

CLEVELAND, Dec. 23—The Chandler Motor Car Co., this city, has increased its wages 10 per cent, affecting all of its employees working on an hourly wage basis. A liberal bonus is given in addition, effective Jan. 2. On July 20, the men employed on an hourly wage basis who are on the company's payroll July 1, will be paid a 10 per cent bonus on the entire wages paid during the year, July 16, 1916 to June 30, 1917.

—

To Talk on Headlight Situation

NEW YORK, Dec. 27—The Illuminating Engineering Society will hold a meeting on the evening of Jan. 10 in the Engineering Building, 29 West Thirty-ninth Street, which will be devoted to the subject of automobile headlights.

A paper is to be presented by W. F. Little of the Electrical Testing Laboratories entitled "A Survey of the Automobile Headlight Situation." This paper will present a symposium of the opinions of various men in the lighting and automobile engineering fields in an attempt to arrive at a consensus as to the requirements. The paper will then describe various headlights upon the market, and in connection with these a demonstration will be made of the lamps in general use, together with several types which have not as yet been placed upon the market.

Following the presentation of this paper it is planned to hold a symposium of engineers, legislative authorities, police officials, etc., in an attempt to secure a good discussion of the headlight problem from a number of different viewpoints.

—

Charter Oak in New Britain

HARTFORD, CONN., Dec. 23—Temporary factory quarters for the newly formed Eastern Motors, Inc., Hartford, makers of the Charter Oak car, have been secured in New Britain, 10 miles from Hartford and the home of the Corbin. At the offices of the concern it is said that Hartford is to be the ultimate location of the business.

Paterson four-passenger chummy roadster added to the line for 1917

Paige Production Expands

Company Installs Conveyors—Increases Floorspace of Factory—Adds Stockroom

DETROIT, Dec. 23—Many changes for the purpose of increasing production have been made in the Paige-Detroit factory in the past year. Particular effort has been expended toward securing the most modern mechanical improvements, and the company has equipped the plant with every efficient device, besides erecting a new structure 60 by 300 ft. and four stories high which is used entirely as a stockroom. The new building is so arranged that one side of the first floor is convenient for delivery by wagon or truck, while the other side opens directly upon the railroad tracks, allowing freight cars to empty into it. The third and fourth floors feed to the structure adjoining, allowing the stock to be efficiently handled on its journey from the stockrooms to the machine shops and assembly departments. The recently added building gives the company more than 500,000 sq. ft. of floorspace, an increase of 40 per cent as compared with space available in 1915.

The assembly work has been arranged upon the progressive plan, and includes several unique features. The building in which machine and assembly work is done is 60 by 600 ft. The third floor is used for the painting and assembling of frames and wheels. The frames enter the room, receive the necessary rivets, and are placed upon a cable conveyor which carries them to a huge tank where they are cleaned with gasoline and given the first coat of paint. From here they travel on the conveyor to the ovens, where they remain for 110 min. and finally emerge dried and ready for the second coat and succeeding oven. Each frame receives three coats of paint, applied by the spraying method, before it is ready for the wheels, which have been assembled on the same floor and include the rims, tires and tubes. A chute at the end of the structure is used to convey the frame to the floor above, where it is placed on a conveyor and travels the entire length of the building, constantly receiving the various parts it needs until it becomes the finished car, ready for final inspection. The conveyor on this floor consists of a double-track system, one for the little six and the other for the big six, and is unique in its construction, as the return cable lies directly under the pulling cable, allowing more floor space for additional work. The tracks run through the center of the room, and stock booths are arranged on each wall so that the workmen may feed the stock, easily and with few steps, directly to the chassis.

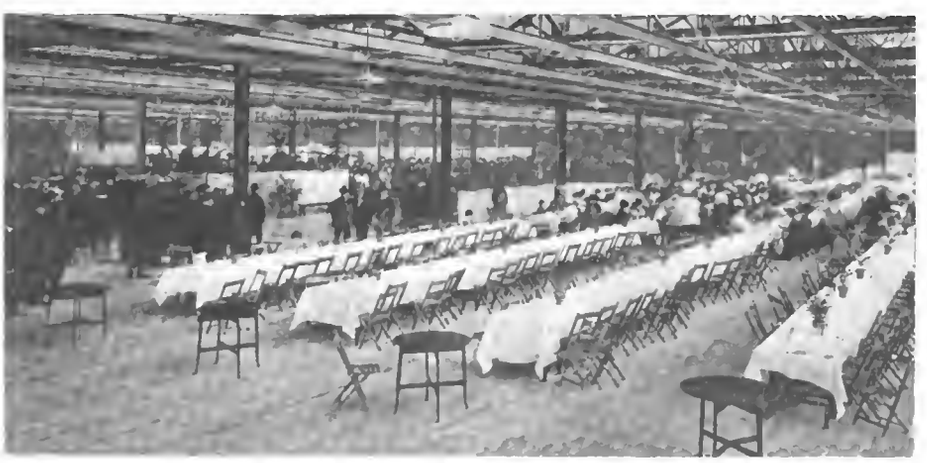
Other floors in this building are used for special paint, equipment and winter top departments, and the entire first floor is devoted to machine work, block testing and adjustment of engines. The block test room is 125 ft. long, and here the engines may be seen hanging from a powerful overhead cable conveyor which carries them in and out of the room for the test. An average of 150 engines are tested daily.

The Paige-Detroit Motor Car Co. employs 900 men now, as against 600 men in 1915. It is doing a business of $2,000,000 a month, as compared with $1,000,000 in 1915. The output this year has been more than 14,000 cars, and plans are being made to increase the production to 20,000 in 1917.

—

Fergus Moves Offices to Newark

NEW YORK, Dec. 22—The Fergus Motors of America has moved its local office at 80 Maiden Lane to Newark, N. J., at 370 Jelliff Avenue.



One of the rooms where the White Motor Co. of Cleveland entertained 6000 persons at luncheon during the dedication of the new manufacturing building of the company last week. While part of the throng were served at luncheon hundreds of others were entertained by Highlanders and by a band of forty pieces and stringed orchestra of twenty pieces, both of which are composed of men in the White plant

N. S. W. Shipments Not Economical

American Makers Should Send Cars Direct to Retailer in Australia

SYDNEY, AUSTRALIA, Nov. 22—The future of automobile sales of American cars in Australia was the major subject of discussion at the annual dinner of the Motor Traders' Assn. of New South Wales last night. The consensus of opinion is that U. S. A. manufacturers are not giving enough attention to shipment of automobiles and the general business in connection with automobile export trade to hold an even scale against European concerns who have given immeasurably more attention to this subject. There was an expected difference of opinion on this subject but the majority of the speakers were of the opinion that Americans do not do their shipping in so economical a way as the British manufacturer.

Practically all of the speakers were displeased with the method of American automobile and accessory manufacturers handling the Australian trade through indent or clearing houses instead of dealing direct with the Australian dealer. It is necessary to pay these indent houses a commission as they are rarely retailers and do not give any assistance to the retailer. They simply control the importation of the article, and collect the middle man's profit without giving any benefit. The disadvantage is that the retailer has his profit cut proportionately. European houses do not follow this plan but deal direct.

Many members of the Motor Traders' Association have visited England recently, within the last few months and have returned with the opinion that British manufacturers are already organizing for the production of standardized motor cars, which will be taken up immediately war hostilities cease. It is not thought that these British makers anticipate competing with Ford but rather that they will be prepared to compete in a price field with the majority of U. S. A. cars selling above the Ford list.

—

First Harroun Building Foundation In

DETROIT, Dec. 22—The foundation of the first unit of the Harroun buildings, at Wayne, was finished Wednesday. The structure will house the assembly units and will be 75 by 540 ft. when completed. The power plant will be started in course of erection within the next 2 weeks.

—

Penn Counties Truck Buys Land

PHILADELPHIA, Dec. 22—The Penn Counties Motor Truck Co., supported by

New York financiers, has purchased a tract of land along the Central Railroad of New Jersey at Allentown, Pa. The work of erecting a plant has already been started. Martin E. Kern, one of the organizers of the International Motor Car Co., is vice-president of the new enterprise which is capitalized at $500,000. Trucks of ½ to 2-ton capacity will be made. The company plans to turn out 2000 trucks complete within the coming year.

—

Hoelzle, of Parker Rust-Proof, Promoted

DETROIT, Dec. 22—E. C. Hoelzle, who has been the assistant to the general manager, has been elected assistant treasurer of the Parker Rust-Proof Co. of America.

—

Cornelius Promoted by Rust Proof

DETROIT, Dec. 21—W. M. Cornelius has been elected assistant secretary of the Parker Rust Proof Co. of America. Mr. Cornelius has been assistant to the president of the company.

—

Core Springfield Body Advertising Mgr.

NEW YORK, Dec. 22—Guy Core has resigned as advertising manager of the Sparks-Withington Co., Jackson, Mich., to take a similar position with the Springfield Body Co.

$1,250,000 Addition in Beloit

Concerns Allied with Automobile Industry Responsible for Bulk of Expansion

BELOIT, WIS., Dec. 23—More than $1,250,000 has been expended in Beloit, during 1916 by industrial concerns for extensions to works, and the bulk of the improvements are attributable to the heavy demands of the gas engine, automobile, accessory, garage equipment and allied interests, according to the annual report of the Beloit Commercial Club, now on the press.

The Stewart-Warner Speedometer Corp. is expending $200,000, providing for 400 more workmen, and adding 81,864 sq. ft. Fairbanks, Morse & Co. added 181,208 sq. ft., provided for 1200 to 1500 more men, and spent $500,000. Other large interests included in the figures are the Lipman Mfg. Co., compressors, garage pumps, etc.; Gardner Machine Co. and Chas. H. Besley & Co., disk and other grinders for metal-working shops, and P. B. Yates Machine Co.

—

Ford Plans Plant for Belfast

DETROIT, Dec. 26—Reports from Belfast, Ireland, state that Henry Ford is seeking a site for a factory to cost $1,000,000 and to employ 2,000 men. F. L. Klingensmith, vice-president of the Ford Motor Co., states that he has heard nothing of the proposed Belfast plant, but that the project is in the hands of the Ford Co. in England. The English Ford company will operate with British capital and directors by paying the Ford Motor Co. royalties on patents. Plans have been completed for factories in Manchester and Southampton.

—

Columbia Starting Production

DETROIT, Dec. 22—The Columbia Motor Co. will occupy its new Detroit quarters on January 1 and will immediately begin production.

—

New Men at Grant Plant

CLEVELAND, Dec. 21—F. F. Wood has been appointed as assistant sales manager of the Grant Motor Car Corp. Mr. Wood was formerly with the Ford Motor Co. at the Akron branch. J. B. Bray, who was formerly with the Curtis Airplane Co., has been made the service manager of the Grant company.

—

Bassett With Buick Company

DETROIT, Dec. 21—Harry H. Bassett has been appointed assistant general manager of the Buick Motor Co., of Flint. Mr. Bassett was formerly general manager of the Weston-Mott Co.

Above are portrayed only a part of the 8000 persons in attendance at a dance given by the White Motor Co. of Cleveland as a feature of the factory house warming in the new manufacturing building, which is 240 by 304 ft. Between dances the guests were shown motion pictures of the factory's products in unusual form of service as well as current feature films. Cabarets were also held

Northwest Conditions Favorable

Though Car Shortage Is Felt, Business Improves and Bank Deposits Grow

MINNEAPOLIS, Dec. 23—General conditions throughout the Northwest are favorable in spite of the reduced wheat crop, railroad car shortage and higher prices of coal. According to the Northwestern National Banks' Review of November conditions, general business is improving, bank deposits are growing and collections are good. Those sections which suffered most from disappointing harvests are not complaining. Even in these districts bank deposits are a little ahead of a year ago. Bank deposits are generally 25 per cent ahead of a year ago.

Car shortage, evidenced at Minneapolis is more serious this year than formerly, and is having an influence on those industries handicapped by lack of cars, and although a larger general business than ever before is being conducted the rolling stock has not been materially added.

A commendable action of one of the railroads is noted in the daily press, that of the tender of the use of its ore cars from certain mining regions in the Northwest to relieve the demand in another section.

Agricultural districts in this territory are not being greatly affected by the car shortage. Some bankers report no particular trouble, though others note some inconvenience. Shippers of hay and potatoes in west central Minnesota are experiencing difficulty in moving their produce. Western North Dakota is finding an insufficiency of cars for its wheat consignments that is surprising considering the crop shortage. It is believed that a considerably larger percentage of wheat was held over from last year in that section than was counted upon. Lumbering interests and loggers in northeastern Minnesota are feeling the car shortage, and it also exists at the head of the lakes. The extensive mining districts of our territory are experiencing no great difficulty. The copper district in northern Michigan is reported as being practically free from the shortage. Grain receipts here are lower than a year ago. The daily average for this market for September, October and November of 1916 is about 945,000 bushels; for the same period last year the daily average was 1,218,000 bushels, and in 1914 and 1913 the averages were 934,168 bushels and 827,761 bushels respectively. Our terminal elevators are filled to about three-fourths their capacity and grain is arriving at the rate of about 900,000 bushels per day. The flour mills are feeling the effect of the car stagnation, but at this writing only two or three of the smaller ones had been forced to stop grinding, and this for very short periods of time. Weather conditions have been favorable for traffic, on the whole, but this cannot be expected to continue as the winter progresses.

—

Bogus District Manager of Commerce Co. Swindles Dealers

DETROIT, MICH., Dec. 23—The Commerce Motor Car Co., truck manufacturer of this city has wired THE AUTOMOBILE as follows:

"An imposter claiming to represent us as district manager is operating in Pennsylvania, West Virginia, and Ohio, passing bogus checks on dealers and hotelmen. These checks are printed with our name and are on the First National Bank of Detroit. Checks are signed F. M. Wilson, manager of sales. The trade should be on the lookout for such a person and wire us promptly in case he is located."—(Signed) Commerce Motor Car Co., Detroit, Mich.

—

Akron-Ardmore Tire Company Formed

ARDMORE, OKLA., Dec. 26—The Akron-Ardmore Rubber Co. has been organized at Ardmore, Okla., with a capital of $1,000,000. John C. Harmony, E. D. Ford, C. A. Besaw, A. C. Fox and R. G. Wood have been active in the formation of the concern.

Steel Prices Rise $5 a Ton

Copper Declines 2½ Cents a Lb.—Kansas Crude Higher—Tin Declines $2.13

NEW YORK, Dec. 27—The materials market last week was on the whole lower. With the exception of a rise in steel prices, the market was otherwise featured with substantial losses in the other metals and rubber. Bessemer and open-hearth steel rose to $60 per ton, a gain of $5. Kansas crude petroleum, accompanied by a general rise throughout the country in gasoline, went up 10 cents a barrel to $1.30.

Aluminum dropped 2 cents to 60 cents a pound. Copper is now quoting 31 cents a pound, a decline of 2½ cents. Tin dropped to $40.50, a loss of $2.13 per 100 lb.

The demand for gasoline is expected to be very large after the war, as its use in Europe is bound to increase enormously. At present in such countries as England, France and Italy restrictions are placed on consumption, and gasoline is so scarce that prices are prohibitive. With these restrictions removed and with the use of the automobile in all countries a growing factor, gasoline requirements will be enormous. The Standard Oil Co. yesterday, probably in anticipation of a larger demand from Europe, raised the price of gasoline 1 cent for export.

—

Fisher Body Sales Increase

DETROIT, Dec. 21—The sales of the Fisher Body Corp. for November amount to $1,650,000, an increase of $180,000 over October, and $400,000 higher than any previous month in the fiscal year. Total sales for the past 9 months are 65.56 per cent higher than for the same period in the previous year.

—

P. R. Creditors Get Dividend

DETROIT, Dec. 21—Creditors of the defunct P. R. Mfg. Co., have received checks covering 5 per cent of their claims. A second distribution of 50 per cent will be made within the next 3 months. The receivership is giving a large return on the common stock in addition to meeting all claims and taking up the preferred.

—

Universal Heater Co. Formed

MARTINTON, ILL., Dec. 26—The Universal Heater Co., this city, has been organized to manufacture a heater for automobiles. Until the company can open its own plant, the heaters will be manu-

factured by the Moline, Ill., Foundry Co. The heater is built in the shape of a foot rest and may be placed either in the rear or front seat of a car and will fit any automobile or other vehicle operated by a gasoline engine.

—

Dividends Declared

Hupp Motor Car Corp. quarterly of 1¾ per cent on 7 per cent cumulative preferred, payable Jan. 2 to stock of record Dec. 20.

Chalmers Motor Corp., 75 cents a share, payable Jan. 15 to holders of record Jan. 5.

Signal Motor Truck Co., 3½ per cent, to be paid Jan. 2 to stock of record on Dec. 26.

Billings & Spencer Co.; extra of 3 per cent with quarterly of 2 per cent, payable Jan. 1 to holders of record Dec. 23.

—

Herschell-Spillman 100 Per Cent Dividend

NORTH TONAWANDA, N. Y., Dec. 26—The Herschell-Spillman Co., this city, will pay a 100 per cent stock dividend, in addition to the regular quarterly cash dividend.

—

Hall Lamp Extra Dividend

DETROIT, Dec. 23—The Hall Lamp Co. has declared an extra dividend of 2 per cent for December on the $600,000 outstanding common stock, making a total of 4 per cent for the month.

Automobile Shares Are Firm

—

Subjected to Severe Grilling at Hands of Bears—General Motors Drops 100 Points

NEW YORK, Dec. 27—Despite the fact that they were subjected to a severe gruelling at the hands of the bears, automobile and accessory securities were conspicuously firm in last week's sensational market. Though the automobile shares were lower on an average last week, they did not decline as much as was expected, considering the light demand before the landslide. The demand picked up, however, and yesterday stocks were higher.

Chevrolet, Hupp, International Motors, Regal and Willys-Overland, featured the market with substantial gains. General Motors, which has been subject to spasmodic jumps of 100 points, either way, dropped 100 points to 500 last week. Springfield Body common was a little weak at 70, a loss of 20 points.

Studebaker and Willys-Overland held up strong with small losses. The common of the latter rose 1¼ points. It is estimated that the profits of the Studebaker Corp. for the fiscal year ending Dec.. 31 will amount to between $10,500,000 to $10,800,000.

The $1,000,000 Paige-Detroit 7 per cent cumulative serial preferred was several times oversubscribed and the books of the underwriters have been closed. The stock, which is now selling above its issue price, was placed largely with investors. It is the first serial issue to be placed by an automobile company and will be redeemed at the rate of $100 par value each year from Jan. 1, 1918, to Jan. 1, 1927, inclusive.

—

General Motors Extends Time

NEW YORK, Dec. 27—The time to exchange preferred and common stock of the General Motors Co. of New Jersey for securities of the General Motors Corp. of Delaware, on the basis of 1 1/3 shares of new preferred for one share of old and five shares of new common for one share of old, has been extended to Jan. 19. Exchanges will be made as of Nov. 1, last. There have been deposited 117,406 shares of preferred and 103,071 of common under the new plan.

—

General Motors on Exchange

DETROIT, Dec. 21—General Motors new common was admitted to the New York stock exchange Wednesday morning. In their application for admittance, the General Motors Corp., which will take over the General Motors Co., stated that of the $45,314,000 common outstanding Dec. 9, the Chevrolet Motor Co. held $16,644,500 in one certificate.

—

Carl Page Takes Over Jordan

NEW YORK, Dec. 27—The Carl H. Page Motors Co., this city, has taken over the distribution of the Jordan car, formerly handled by John G. Dale, a former distributor of the Simplex and now handling the Phianna.

Pilgrims from Abroad

MORE automobile engineers, manufacturers and dealers from other lands will attend the coming national shows at New York and Chicago than ever before in the history of the industry. For months many of them have been visiting factories in our great production centers, studying methods of manufacture and marketing as well as the points of construction in the cars themselves.

Now they will have an opportunity of viewing the products which will represent the industry for 1917, grouped under the most favorable conditions possible for imparting a correct perspective.

When a representative of an U. S. A. manufacturing firm returns from abroad, he is immediately besieged by people who are anxious to learn the conditions and opportunities for business development in the countries he has visited, and it is not only the people with whom he comes into daily association who seek this information. Often he receives letters and telegrams from companies and individuals all over the United States who are interested in his experiences and the knowledge he has gained. Similarly with the men from other lands who return from a sojourn in this country.

It must be remembered that these men will carry home with them impressions of our methods, our products and their value, which cannot fail to influence the markets in their respective countries, and every member of the industry who comes in contact with these men should keep this fact in mind, as it may mean an enormous difference in dollars and cents in the future development of our export business.

The Little Things

WHILE newspapers and the trade press have frequently lectured American manufacturers for slackness and lack of perspicacity in handling their export business, there is apparently some basis for complaints on the subject. For example, Latin-Americans, in buying tires of European manufacture, have been accustomed to receive inner tubes packed complete with nipple, washer and dust cap, so that they can be put on without depending on possible relics in the possession of the purchaser. Many of the leading tire makers of the United States, partly due to increased cost of materials and manufacture, and partly because of no demand for these details of equipment on the part of U. S. A. car owners, have discontinued the practice of furnishing these parts with their inner tubes. This action has caused no complaint in this country, which is perhaps the reason that these tire makers have not considered its effect on their export business.

In Cuba, Porto Rico and the South American countries, the omission of these almost negligible details has caused much dissatisfaction with the result that many car owners who have been converted to the use of U. S. A.-made tires since the beginning of the European war will return at once to the use of European tires as soon as possible.

Our manufacturers should be careful to take into consideration at all times not only the different conditions under which their products operate in other countries, but also the peculiarities of demand in each market which can only be brought to the surface by a close study and intimate relationship with the people who are buying these products.

A New Era

THE year just closing marks a new era in the automobile industry, one that has been unequaled in production and progress. Hampered on every side by a shortage of materials, with high prices, higher wages, and a freight car shortage, the manufacturers are to be commended on their wonderful showing. Financial statements show much larger returns, dividends have been frequent and large, and in general the automobile and allied industries have gone up another step toward the pinnacle of success.

What are we to expect of 1917? What new marks will be recorded? Will we be prepared for conditions, if the war should stop? What new production marks will be made by the further standardization work of the S. A. E? The year 1916 has been phenomenal in the demand for automobiles. Will 1917 mark another record, and if so, are we prepared to take care of it?

1916

The Dawning of a New Era in The Industry

¶ Unparalleled Growth in Production, Registration and Exportation of Cars Marks New Epoch in Progress During the Year.

¶ Notable Development of Year Is Consummation of Mergers Involving Large Companies and Refinancing To Meet New Conditions Which Now Confront Manufacturers.

AS each year comes and goes, there is usually some dominating feature, marked and epoch-making, brought out in the industrial world. either through invention, or through other important manifestations. The automobile industry, which is occupying a leading position in the world's business activities, has each year come to the fore with its progressiveness and with its keen insight to the future. The year 1916 will be recorded as one in the automobile industry of unprecedented production and expansion, of record earnings and exports, of big mergers, and of an increased domestic demand.

This year has seen the farm tractor enter the zone of larger production. A step ahead has been taken by aviation, and the government's huge appropriation of tens of millions should have untold influence on the science, coming as it does at such an early age in the art.

Over 3,000,000 Cars

Notwithstanding a scarcity of materials and consequently high prices, automobile registrations have passed the 3,000,000 mark, some of the large cities having more automobiles registered than a few of the European countries. This year has seen the reduction of the working day, with large wage increases. Extraordinary dividend payments have been frequent, reflecting the large earnings of the automobile and accessory industry. Welfare work has been taken up more extensively, the worker being benefited by more hygienic working conditions. More companies have been refinanced than in previous years as a result of demand. A record demand has had to be taken care of, thereby necessitating large plant additions. All automobile shipment records were broken in 1916, despite a freight car shortage, nearly 250,000 carloads of automobiles being shipped by the factory during the first 11 months.

Several patents have been adjudicated during the year. The Perlman demountable rim suit against the Standard Welding Co. was of more than ordinary interest, because it affected the use of demountable rims on nearly all the automobiles made and now in service. The restrictive injunction, entirely preventing manufacture, was for a time one of the most serious situations faced by the industry in many years.

Important Patents Adjudicated

The Hanlon adjustable windshield patent, which had been adjudicated and declared valid and infringed by Rauch & Lang and the National Automobile Chamber of Commerce, was brought before the United States Circuit Court of Appeals, where the injunction was dissolved, affecting all the members of the National Automobile Chamber of Commerce and also the Rauch & Lang Carriage Co. The Hanlon patent covers a windshield using a double glass, which can be placed at an angle, forming a roof to keep rain or sleet from the vertical pane. The device is now free for general use.

The final decree in the Austin-Cadillac two-speed axle case was signed in the early part of the year, sustaining the patent and preventing its manufacture except under license. Suit was started by W. S. Austin, of the Austin Automobile Co., in 1914, claiming infringement on his two-speed axle patent, No. 1,091,618, issued March, 1914.

Other patents were upheld, including the Discher patent covering a bumper bracket construction. G. F. Discher, president and general manager of the Gemco Mfg. Co., Milwaukee, had brought suit against the Auto Parts Mfg. Co. for infringement on patent No. 1,052,224. This broadly covers radiator bumpers which are attached to the frame with adjustable clamps, thus avoiding drilling of the frame side members.

Another patent upheld was that issued to D. McRa Livingston, No. 1,156,017, covering a mask for concealing the engine and radiator casing of a

December	——	15,582	7,378

Ford car. The patent permits of a combination hood and radiator mask which gives a distinctive stream-line effect.

Several patents are now before the courts, one being the Springfield type body. The suit is against the Fisher Body, charging infringement of design patents, Nos. 47,252 and 47,630, covering the Springfield type of convertible and four-door bodies.

Exports Pass $100,000,000

Automobile, truck and accessory exports this year have far passed the $100,000,000 mark. The wonderful showing the United States has made in the shipment of automobiles to foreign countries is reflected in the figures for the first ten months, a total of 67,616 cars and trucks, valued at $100,147,636, compared with 53,380 cars and trucks, and $94,434,432 in the same period in 1915, the war being the potent factor in this growth. Notwithstanding the restrictions made by Great Britain, Italy and France on the importation of our cars and trucks, the export figures have increased each month. Foreign markets, formerly supplied by Europe, have been developed, and the United States is fast getting a foothold which is not only continuing, but will mean increased sales after the war has stopped. South America is developing as an automobile field, shipping conditions are being bettered, and better credit relations are being opened. Australia, which for the past two years has been a large buyer of American cars, bought more of our cars and parts this year than ever before. British South Africa has prospered greatly because of the war, and here purchases of our automobiles and accessories have greatly increased. The West Indies have developed much as automobile consumers during the past year.

Automobile and commercial vehicle exports are now receiving more attention by the makers. A majority of them are building their cars with larger treads and with right or left steering, according to the demand from the specific locality. Special representatives are being sent to different parts of the world to study conditions and the American makers are fast taking advantage of the openings for increased trade caused by the war.

Truck exports during the year have not been as large as in 1915, but passenger car exports have averaged about 1000 more each month over the corresponding month of 1915. Truck exports have been lower since April. The American automobile, especially the medium and low-priced models, have proved popular in foreign countries, especially those not now engaged in war. These countries are sending men to the United States to investigate the automobile industry and ultimately to open agencies in their own countries.

More combinations of business interests in the automobile field have been made this year than ever before. Nearly twenty new companies have resulted from mergers, affecting fifty concerns. One of the large mergers during the early part of the year was the formation of the United Motors Corp., with a capital of $60,000,000, including at that time five of the largest parts and accessory making concerns. It has since merged four more concerns. Another important merger was that of the Motor Products Corp., a combination of five parts makers from the Detroit territory. Then came another merger of parts companies into the Steel Products Co., Detroit. In order to concentrate production, the Signal Motor Truck Co. and the Commerce Motor Car Co., Detroit, effected a merger, known as the Signal-Commerce Motor Truck Co.

Another consolidation was that of the Perfection Spring Co. and the Standard Welding Co. into the Standard Parts Co., Cleveland, capitalized at $35,000,000. This merger was important in that it eliminated the friction regarding the Perlman rim patents, as the Standard Parts Co. had contracts with the Perlman interests, permitting manufacture of demountable rims at a fair profit.

Monster Merger Plan

So far there has been no combination of the automobile companies, the nearest to that being the monster merger planned in June. According to plans, there was to be a capitalization of $223,000,000, and was to include Overland, Hudson, Chalmers, Auto-Lite and the United Motors. If the plans had not miscarried, this combination would have ranked in magnitude second only to the U. S. Steel company.

On account of the record output of the automobile and allied plants, the year 1916 has been one of large factory expansion, and, as a result, many of the companies were induced to refinance or reorganize. Others have added considerably to their capital, to take care of needed factory additions.

Thirty-Six New Companies

That the need for new capital has been well distributed is indicated by the fact that of thirty-six companies, which have refinanced and changed their names or reorganized, thirteen were automobile producers, seventeen accessory makers, and six truck manufacturers.

The large demand for the American automobiles and accessories was responsible for the formation of many new companies this year. Out of an approximate total of 130, a large majority of these companies have finished their organization work and have started the erection of plants. Some of them are producing, despite the shortage of machinery and the high cost of materials. New automobiles and many new accessories have been put on the market, and are finding a big demand.

During the year many men, formerly connected with the automobile industry, branched out for themselves by forming new companies. One of these companies, and one which is now producing, is the Jordan Motor Car Co., Cleveland, maker of the Jordan automobile. E. S. Jordan, formerly secretary and general sales manager of the Thomas B. Jeffery Co., together with Paul Zens and R. S. Begg, were the organizers. Later came the organization of the Liberty Motor Car Co., by Percy Owen, formerly connected with the Saxon company in the capacity of vice-president and sales manager.

The Columbia Motors Co., Detroit, was another new company formed by men prominent in the automobile field. Both these men, J. G. Bayerline and W. L. Daly, were formerly connected with the King Motor Car Co.

The year 1916 was featured by the entrance of many notable outside manufacturers into the automobile field. One of the most prominent was the Brunswick-Balke-Collender Co., Muskegon, Mich., maker of billiard tables, bowling alley fixtures, etc. This firm has started the manufacture of tires. Another concern to enter the field was the Niles Car & Mfg. Co., Niles, Ohio, maker of railroad cars. This concern is now making ¾ to 1-ton and 2 to 2½-ton trucks. During the latter part of the year A. Howard, pioneer in the buggy business in Galion, Ohio, formed a company to produce an assembled car.

Many Big Dividends

Dividends this year have been frequent and large. A number of the makers have bought back certain issues of stock and a majority of them have put their stock on a higher dividend paying rate. One of the largest dividend payments of the year was that of the Diamond Mfg. Co., which declared a 300 per cent cash dividend as a result of the change of control at the time of being taken over by the Motor Products Co. Several of the companies declared large stock dividends, ranging from 50 to 108 per cent, the latter being given by the Haynes Automobile Co. Several of the automobile makers have put their stocks on an 8 per cent basis, one of the first being the Chandler Motor Co., Packard Motor Car Co., and the Pierce-Arrow Motor Car Co. The Maxwell Motor Co. inaugurated quarterly payments of $2.50 per share on its common, practically putting that stock on a 10 per cent basis.

This year has been featured by a general rise in automobile prices on account of the increase in the cost of materials. The year previous saw a general reduction in the list price of automobiles, due to improved factory machinery, conducive of a much larger production, and to a general reduction in material prices. As wages, rents, and nearly everything that goes into the manufacture of automobiles have risen, it is remarkable that the makers have held their increases on an average to so low a mark. That the accessory people have taken care of the future is proved by the fact that few have gone up in price; a small number have announced reductions. Prices on automobiles for 1917 will show increases ranging from $20 to $300.

During the first 6 months of 1916 a great many of the leading automobile manufacturers announced increases in price on their various models, but as these were the past season's models they are not included in the list appearing on page 1092, which is made up of the changes in price announced since July 1. During the past month there has been almost a landslide toward higher prices due to the greatly increased cost of the materials which enter into the construction of chassis, body, and every part of the car. In some cases, an example of which is Maxwell, the company announced a reduction in prices during the summer only to find that the increase in the cost of production did not permit of continuing at this figure, with the result that higher

AUTOMOBILE EXPORTS

*To Dec. 18.

prices had to be announced. In the case of Maxwell, however, the new prices are still considerably lower than those in effect before July 1, so this case is an exception. Ford is the only other company which has lowered its prices during the past 6 months. There seems to be very little uniformity in the amount of increase made by the different manufacturers, doubtless due to the fact that each maker has his own individual problems to solve and finds conditions different at his factory from those to be found at other centers of production. As a rule the cars selling at under $1,000 have increased their prices anywhere from $10 to $50; cars selling from $1,000 to $2,000 adding from $50 to $300; and cars selling at $2,000 up, increasing their list from $300 to $600.

Automobile production far outstripped previous efforts. During the first half of the year, 754,902 automobiles were produced. This output of 6 months is little behind the entire output for 1915, which was 892,618. Ninety-nine factories were included in this 1916 figure, and of these 96 per cent being made in Michigan, Ohio and Indiana. During the first half of the year, Ford manufactured 298,000 cars, with Overland next with 94,477. In the year ending Aug. 1, Ford recorded a production of 533,921 cars, an increase of 225,708. Truck production for 1916 is estimated at 98,000

Shipments Break All Records

Shipments this year have been unparalleled, notwithstanding a freight car shortage, which for a time menaced the industry. Carload shipments passed the 1916 mark in the first 11 months, amounting to 249,755 carloads up to the end of November, as compared with 192,575 in the whole of 1915.

Many Concerns Refinanced

Prominent among those automobile producers which inaugurated extensive expansion policies by refinancing are: Chalmers Motor Co., taken over by the Chalmers Motor Corp., with a capital of 600,000 shares of no par value; National Motor Vehicle Co., Indianapolis, taken over by the National Motor Car & Vehicle Corp., with an offering of 53,000 shares at $42.50 per share; Pierce-Arrow Motor Car Co., Buffalo, taken over by the Pierce-Arrow Motor Car Corp., formed with 100,000 shares of 8 per cent convertible preferred and 250,000 shares of common without par value; Mitchell-Lewis Motor Car Co., Racine, Wis., taken over by the Mitchell Motors Co., with a capital consisting of 125,000 shares of common without par value; Thomas B. Jeffery Co., Kenosha, Wis., taken over by C. W. Nash, former president of the General Motors Co., and Lee, Higginson & Co., Boston, with the formation of the Nash Motors Co., capitalized at $24,999,500; Stutz Motor Car Co., Indianapolis, taken over by the Stutz Motor Car Co. of America, with a capital of 75,000 shares, no par value.

The Royal Equipment Co., Bridgeport, Conn., in order to take care of expansion, formed the Raybestos Co., with a $1,500,000 capital. Another prominent accessory concern to refinance was the Auto Crank Shaft Co., Detroit, taken over by the Automobile Crank Shaft Corp., with a stock issue of $250,000, divided into 2500 shares of 7 per cent cumulative preferred stock and 7500 shares of common of no par value. The Pennsylvania Rubber Co. was reincorporated with a capital of $6,000,000, increasing its capital $4,000,000. The Torbensen Axle Co., Cleveland, was formed to take over the Torbensen Gear & Axle Co., the new company having a capital of $1,000,000 preferred and $750,000 common. Late this year the Hess-Bright Mfg. Co. announced that controlling interest in its company had been purchased by a group of financial men, who also own a substantial interest in the S. K. F. Ball Bearing Co. The Hess-Bright manufacturing facilities are to be increased materially, though the two companies will be operated quite independently of each other.

One of the first of the truck companies to add new capital was the Republic Motor Truck Co., which incorporated with a capital of $1,312,500, divided into 72,500 shares, 62,500 without any par value, and 10,000 with a par of $1,000 a share. Another prominent truck maker to expand this year was the Gramm-Bernstein Co., which reorganized and increased its capital stock to $4,000,000, forming a new company under the name of the Gramm-Bern-

stein Motor Truck Co. The capital is composed of $3,000,000 common and $1,000,000 preferred. The reorganization plan of the International Motor Co., New York, was approved by the stockholders and creditors, and as a result the International Motor Truck Corp. was formed to carry on business with $7,372,790. Thus additional capital of $1,500,000 was raised, and the $2,881,000 notes maturing the first of November were obliterated. Another prominent concern, the Smith Form-A-Truck Co., in order to enlarge production, was taken over by Michaelis & Co. and banking associates, who formed the Smith Motor Truck Corp., with a capital of 20,000 shares of 8 per cent cumulative and convertible preferred stock, and 1,200,000 shares of common, par $10.

Accessory Companies Expand

As was expected, the accessory makers would need additional space during the year. Some of them took care of their increased facilities through the ordinary channels, others added capital, and still others were forced to follow the lead of the automobile makers, and refinance. Stromberg Carbureter Co., Chicago, was one of the first to refinance when it went under new control. The Stromberg Carbureter Co. of America was formed under the control of Allan A. Ryan & Co. and a syndicate of prominent banking interests in New York. The new company issued 50,000 shares of no par value. Another was the Empire Rubber & Tire Co., Trenton, which formed a new company, the Empire Tire & Rubber Co., capitalized at $1,500,000 preferred and $4,500,000 common. As a result of increased business, the A. O. Smith Co. was taken over by the A. O. Smith Corp., Milwaukee, with an offering of $3,000,000 preferred and 100,000 shares of common. The Kemco Electrical Mfg. Co., Cleveland, was reorganized with an entirely new ownership and personnel.

Factory additions were large as usual, there being 9,362,881 sq. ft. added by all the branches of the automobile industry, costing $9,449,065. Additional equipment cost $8,233,190, making a grand total of $17,682,255, as compared with $12,886,345 in 1915.

Welfare Work Progresses

More attention this year has been given to the betterment of working conditions. Club houses, athletic fields, etc., have been installed in a large number of the factories. Working conditions have been improved, labor-saving machinery installed, improved lighting arrangement, shorter hours and increased wages, all have worked toward bringing about a complete change for the better. Firestone Tire & Rubber Co. opened a large clubhouse for employees. Many other concerns added materially to their welfare work.

Another interesting development of the year has been the indorsement of the principles set forth by advocates of the Safety First movement, especially with regard to protecting the workers from bodily harm by machinery or accidents of any kind in yard and factory. Among the companies who have taken up this phase of the welfare work possibilities may be mentioned the Republic Rubber Co., which has recently installed devices for safeguarding its employees at every point throughout its plant and yards where danger might arise.

In addition to caring for the bodily safety of their workers, most of the leading automobile and accessory manufacturing concerns have devised plans of assisting employees in developing their economic welfare. Arrangements whereby a certain amount of each worker's earnings may be put in a savings fund or other similar institution regularly are common in nearly all the large factories, as are also co-operative plans providing for life and accident insurance as well as sick benefits. Clubhouses for employees provide entertainment, exercise and social recreation outside of working hours and in other ways the workers are cared for.

Engineering Development

There is no vast advance in design to chronicle, as was the case a year ago. The design of American cars was improved enormously during 1915, and 1916 has been a year devoted mainly to improving the methods of manufacture and cleaning up little details of design. The high spots of the 1917 cars are better lubrication, easier controls and steering, and still more comfortable bodies. The V-engine has made no great advance, the six and four hold about the same proportion that they exhibited last year.

Materials Are Better

The terribly difficult conditions of the markets and the greater stresses called into being by higher speed engines have together caused engineers to give more attention to materials. It has been neces-

DIVIDENDS DECLARED

Company and Nature of Dividend

H. H. Franklin Mfg. Co.—100 per cent stock dividend on common.
General Motors Co.—Common on 20 per cent basis.
Packard Motor Car Co.—10 per cent stock dividend on common and cash dividend of 1¾ per cent.
Studebaker Corp.—Quarterly of 1½ per cent and an extra of 1 per cent on common. Also regular 1¾ per cent on preferred. Common placed on 10 per cent basis in August.
Continental Motor Mfg. Co.—100 per cent stock dividend and 5 per cent on common.
Chandler Motor Car Co.—Stock on 8 per cent basis. Extra cash dividend of 1 per cent.
Hydraulic Pressed Steel Co.—50 per cent stock dividend.
Miller Rubber Co.—66⅔ per cent stock dividend on common.
Paige-Detroit Motor Car Co.—80 per cent stock dividend on May 24 and a 50 per cent stock dividend on Sept. 6.
Willys-Overland Co.—Common on 12 per cent basis. Extra stock dividend of 10 per cent.
Haynes Automobile Co.—Stock dividend of 108 per cent.
Maxwell Motor Co.—Common on 10 per cent basis. $7 a share on preferred and $6 a share on second preferred.
Bower Roller Bearing Co.—Quarterly of 15 per cent cash. Recommended stock dividend of 100 per cent to be approved by holders at January meeting.
Sparks-Withington Co.—2 per cent on common for 6 months; also 1¾ per cent on preferred.
White Motor Co.—$1 a share, placing stock on 8 per cent basis.
Four Wheel Drive Automobile Co.—Stock dividend of 100 per cent and cash dividend of 30 per cent.
Kelsey Wheel Co.—50 per cent stock dividend on common.
Auto Body Co.—209 per cent stock dividend and 5 per cent cash.
Firestone Tire & Rubber Co.—$4 a year on new common with a par value of $10.
Saxon Motor Car Co.—Stock on 7 per cent basis.

sary to discover means for doing without some of the higher grades; for instance, there has not been anything like enough tungsten to allow all those makers who wanted it to get a supply. In consequence we have now got some tungsten substitutes which are doing good service.

A feature of the year's engineering work, which must be mentioned, is the way in which several of the leading manufacturers have turned their attention to aircraft motors. Some openly and some behind locked doors have been working engines for airplanes, and there are now American motors as good as the best of the European ones in existence. They are hardly yet in production, but they will be next year.

Carburetion has, perforce, received much attention, owing to the increasing trouble with low-grade fuel, and manifold design has been modified also, the principal aims being to atomize the fuel more completely and keep it hot till it is actually ignited. Ignition has been featured by a general improvement in the construction of battery systems which are stronger and simpler. Transmission has not changed, though some new electric drives will be found at the shows. Frames are stronger and more rigid, and spring design is better, the attention this received in 1915 now bearing fruit.

In brief, the automobile of 1917 is just a bit better job all around than was the car of 1916. Its average price is a few dollars higher, but more than enough value is being given in return.

Materials Cost More

The material markets have played an important part in the activities of the automobile industry. Prices have reached record quotations on account of the large demand and the small supply. Steel prices have risen skyward, reaching $60 a ton in December, practically double the quotation in January. Copper is higher, beams and channels are much above their quotations of January.

Pennsylvania crude petroleum has risen to $2.60 per barrel, the highest price in its history. Gasoline has fluctuated throughout the year. When retail prices reached the 30-cent a gal. mark, Federal investigation resulted in a small decline. Prices are now above normal.

Rubber and cotton duck prices were higher, the latter rising from 50 to 96 cents a lb. Naturally automobile and tire prices went higher. Tire prices rose 15 to 20 per cent in the early year, and a similar increase is looked for in January.

The crude rubber market opened in a very unsatisfactory condition, with Para selling at 95 cents a lb. and Ceylon at $1.05. With the Suez Canal temporarily closed, and submarine warfare hampering shipments, prices rose to new heights. Cotton was at that time costly, and compounding ingredients were at prohibitive prices. Naturally with over 60 per cent of the crude rubber used coming from the Eest, and with an increased demand, a general rise was imperative.

These high crude rubber prices, however, were short-lived, for in February and March quantities of rubber scrap, notably automobile tires, came into the market. Under improved reclaiming processes this surplus became crude rubber, and proved one of the factors in driving the price down to a reasonably low figure. Prices gradually dropped from 73 cents for Para and 75 for Ceylon in February to 63 and 62 respectively in July. Ceylon reached 57 cents a lb. in August, and is a little higher at the present time. Para rose in October on account of an unusual drought on that river.

The Year in Speed Events

The year has been a 100 m.p.h. speedway era. All records on speedways and road have been broken, all transcontinental records have been shattered, and new marks in fuel economy have been made. In ten of the events, 100 m.p.h. or over was recorded. This year saw twenty-one finishers with an average of better than 100 m.p.h. in speedway races.

A new 24-hr. record was made by a Hudson Super-six, which traveled 1819 miles in that period, shattering the old record by 238 miles, made by Edge in a Napier at Brooklands.

A new transcontinental record was made by a Hudson, which covered the San Francisco-New York trip in 5 days, 3 hr., and 31 min., making the round trip in 10 days, 21 hr., and 3 min. The year witnessed three well-planned and executed attacks on the transcontinental mark. Cadillac opened the drive in May, cutting the old figure, 1 day and 14 hours. In July Marmon cut this figure by nearly 2 days, and lastly came the Hudson, establishing the present record.

Car Price Increases

Car	Change	Effective
Hudson	$175	Dec. 1
Maxwell	$60 lower on Tourer $55 lower on Roadster	July 1
Reo	$100 lower $75 lower on truck	Aug. 5
Dort	$30	Aug. 1
Ford	$35 to $95 lower	Aug. 1
Ross	$200	Sept. 1
Chevrolet	$50 on Baby Grand	Aug. 26
Daniels	$200	Sept. 1
Chalmers	$70 on 7-Tourer $90 on Sedan $70 on Town Car and Limousine	Dec. 1
Pullman	$85	Oct. 24
King	$50	Nov. 6
Cole	$100	Jan. 1, 1917
Packard	$185 on Model 225 $235 on Model 235	Feb. 1, 1917
Marmon	$150	Jan. 1, 1917
Kissel	$90 to $115	Dec. 1
McFarlan	$300	Dec. 1
Chase Truck	$75	Nov. 27
Riker Truck	$100	Dec. 1
Winton	$200	Dec. 15
Saxon	$50	Jan. 1, 1917
Premier	$200 to $215	Dec. 1
Allen	$100 on Closed Cars	Jan. 1, 1917
Mitchell	$100	Dec. 1
Cadillac	$160	Dec. 14
Mack Truck	$100 to $250	Jan. 1, 1917
Austin	$350 to $600	Dec. 11
Buick	$10 Model D-4-34 and D-4-35 $55 Model D-6-44 $50 Model D-6-45 $15 Model D-6-46 $35 Model D-6-47	Jan. 15, 1917 Jan. 15, 1917
Maxwell	$40 Touring Model and Roadster	Jan. 1, 1917
Franklin	$100 all models	Mar. 1, 1917
Standard	$100 all models	Jan. 1, 1917
Auburn	$60 Model Six	Jan. 1, 1917
King	$185 seven and four-passenger touring cars and roadster $200 on seven-passenger sedan	Dec. 19, 1916
Stanley	$225 five-passenger and seven-passenger touring $250 seven-passenger sedan	Dec. 4, 1916
Paige	$120 on Model 51 Stratford $85 on Model 39 Linwood $105	Dec. 19, 1916

S. A. E. Adds 36 Standards in Year

1916 Proves Epochal Period in Society's Development—Horizon Widens with New Year

ON many occasions when writing of the Society of Automobile Engineers its immensely rapid progress has been the theme. Year by year, it seems, the pace increases, and 1916 has been more important to the S. A. E. than any which have gone before. In fact it has actually been an epochal year for the society, for it has seen the S. A. E. make its way forward till it stood among the leading engineering societies of the world 2 years and more ago. In 1916 it has amalgamated with the aeronautic engineers and it is extending its activities to care, in a specialized way, for tractor and marine motor engineering.

Probably the biggest factor in bringing to pass the broadening of the society's scope is the work of standardization accomplished by the S. A. E. in the automobile field and the obviousness of the immense amount to be done in the other allied industries. That of the aeroplane has already been begun and new divisions of the standards committee will soon spring into being to look after the other departments.

As the outward and visible sign of the society's growing activities is the change of name to Society of Automotive Engineers, which will certainly be ratified at the January meeting of 1917. From the automobile industry, the aeroplane, tractor and motor boat industries have branched out and automotive is a peculiarly happy word to express the wide field they cover. Previously there has been no one word which could be used in a generic sense to cover all these new allied industries. We are now provided with one and it is likely that automotive engineering will be used in the way it is intended throughout the English-speaking world.

The enlargement is being accompanied by a substantial increase in membership, and the total of 2121, 317 more than on Jan. 1, 1916, at which the society now stands will certainly be much increased very soon. Not only is the broadening of scope bringing in many members, but it is bringing keen men, enthusiasts in their subject, into the organization. The newer branches of the automotive industry have been created by the most active and most persevering types of men, men who will use the opportunities of membership to the full.

Immense Growth of Sections

There is no better index to the much greater use which the membership is making of the advantages of membership than the amazing change that has taken place in the character of the meetings of the sections. Two years ago the Detroit section met in a small room; to-day it uses the largest gathering place in the city and shows attendance at papers and discussions equal to, or even greater than the near 700 members of the section. Cleveland has shown similar growth, the rise of the new section being even more rapid, though it has not yet reached Detroit's totals. The Metropolitan section has had better gatherings than ever, while the Mid-West section at Chicago and the Pennsylvania at Philadelphia are growing healthily. Within the past month the Buffalo section has been created, and bids fair to be soon among the largest, if the meeting for its formation may be taken as any indication. Buffalo now having so many aeronautic engineers at work within it is likely to be a place where papers and discussions on this phase of automotive engineering will be common.

Giving the figures in order of magnitude, Detroit has 710, of which 361 are section associates; Cleveland has 268, of which 122 are section associates; the Metropolitan section has 235, sixteen being associates; the Mid-West has seventy-six, with twenty-six associates; Indiana has sixty-seven, fourteen being associates and Pennsylvania forty-five, with twenty-one associates. These associates are members of the sections only, and not members of the parent society, but it is probable that a majority of this 560 men may become so.

Standards Finally Accepted by S. A. E. in 1916

JANUARY MEETING

1—Instructions for testing materials and some new standard test specimens.
2—Cone clutch flywheel housing (bell housing).
3—Basis of speed and mileage rating for electric vehicles.
4—License plates and brackets.
5—Tire pump bases.
6—Location of chassis number.
7—Location of engine number.
8—Sizes of hose connections.
9—Lock washer dimensions.
10—Forms for specifications and methods for commercial testing of springs.
11—Sizes and specifications for insulated wires and cables.
12—Industrial truck tires.
13—Diameters of truck tires.
14—Dimensions of truck wheel felloe bands.
15—Standard weight definition.
16—Piston ring groove widths (part of final complete standard).
17—Location of slots in headlamp bulbs (revised later).
18—Resolution in favor of 42-in. rule for minimizing headlamp glare.

JUNE MEETING

19—Standard nomenclature.
20—Series of standard sizes of flexible metallic tubing.
21—Headlamp bracket dimensions.
22—Minimum height of headlamp above ground.
23—Resolution that current reducing dimmers are of no value for glare reduction.
24—Specification (partial) for focussing device.
25—Location of headlamp bulb slots.
26—Revision of bulb nomenclature.
27—Fitting and wiring of storage battery.
28—Throttle lever rod ends.
29—Throttle lever end throw.
30—Charging plug receptacles for electric vehicles.
31—Nickel steel.
32—New table of physical tests of several S. A. E. steels.
33—New test specimen recommendations.
34—Formula for and tabulation of sizes of piston ring grooves (final form).
35—Increase of length of thread on S. A. E. bolts.
36—Complete tabulation of taper roller bearing sizes.

The work of the standards committee is about to be reorganized, having now grown to such dimensions that the old system is developing weakness in places. During the year the committee divisions have mostly been very active and a number of difficult subjects have been disposed of. The actual number of new standards is not large, but those which have been accepted are mainly of a really useful character. In some respects the difficulty of getting agreement on standards increases just as the demand for them grows. Standards are now being worked out for things which a short while ago were declared unstandardizable, mainly because individuals who used to be jealous competitors have discovered the immense advantages of getting together.

In January K. W. Zimmerschied resigned the chairmanship of the standards committee having, in his time of office, stimulated the work to an enormous extent and by constant personal appeal, spread the standardization idea far and wide. With the appointment of A. Ludlow Clayden, the chairman for 1916, several divisions were discontinued and such work as they had unfinished turned over to other divisions. At later dates there were created the tire and rim division, which is now proceeding rapidly with the standardization of pneumatic tires and

rims under the chairmanship of K. W. Zimmerschied; and the aeronautic engine division, Chairman Henry Souther, which has a hard task before it in getting order from the present chaos of aeroplane engine detail. Also the nomenclature committee was created a regular division, also under Mr. Zimmerschied's chairmanship.

Standard nomenclature for every part of an automobile chassis was accepted by the society at the summer meeting and an illustrated book containing all the names will probably be published in the spring of 1917.

Three meetings of the standards committee have been held, one in April at Cleveland; the second at the summer meeting on the Noronic and the third at the Bureau of Standards, Washington, in October. The standards accepted at the summer meeting are listed on this page and a number of others will be submitted to the January meeting for acceptance.

Throughout the year the electrical equipment division has been concerned mainly with matters relating to lamp standardization and headlamp glare and much useful detail work has been done, though there has been no settlement of the glare problem in the form of a general resolution.

The truck standards division has been reorganized as to personnel now being composed entirely of engineers from truck factories under the chairmanship of H. D. Church. The division has been mainly concerned with military specifications and has been in close touch with Washington on this subject. Its most important accomplishment is the formulation of a standard control which will come up for acceptance in January.

The big work of the engine and transmission division has been the revision of the engine test forms which is now just finished, and another important work nearing completion is a standard for generator and starting motor mounting, this being handled by a sub-committee of both the engine and transmission and the electrical equipment divisions.

The miscellaneous division has completed its piston ring groove standardization, has examined with great care and finally reported as impossible, a standard speedometer drive and has several recommendations for the January meeting. Steering wheel hub standards, taper fittings for such things as fender irons, fine pitch threads and a number of other similar matters are in an advanced stage.

The ball and roller bearing, the iron and steel and the electric vehicle divisions have proceeded steadily and have several new standards to their credit. The springs division, which presented a voluminous report last January, has recently completed some additions, principally relating to spring bolts and spring clips which are nearly ready for acceptance. The research division has devoted the whole year to the perfection of the recommended form of procedure for testing a car for fuel economy and acceleration. Some tests of the system have been made and further tests are to be made.

Financing a Feature of the Year

Many New Companies Formed, Important Mergers Consummated and Rearrangement of Finances Effected

New Companies

A. B. C. Starter Co., Detroit, Mich. Capital $150,000—A. B. C. Ford starter—Jan.

Jordan Motor Car Co., Cleveland, Ohio. Capital, $800,000—Jordan cars—Jan.

Liberty Motor Car Co., Detroit, Mich. Capital, $400,000—Liberty car—Feb.

Harding Motor Car Co., Cleveland, Ohio. Harding Twelve—Jan.

Columbia Motors Co., Detroit, Mich. Columbia car—Feb.

American Motors Corp., Plainfield, N. J. Capital, $1,250,000—American car—Feb.

States Motor Car Mfg. Co., Kalamazoo, Mich. Capital, $600,000—States car—Feb.

Castaluminum Body Co., Detroit, Mich. Capital, $100,000—Aluminum bodies—March.

Fergus Motors of America, New York. Capital, $2,000,000—Fergus car—March.

Roto Motor Co., Hannibal, Mo. Capital, $350,000—Roto truck—March.

Twin City Four Wheel Drive Mfg. Co., St. Paul, Minn. Capital, $1,000,000—Trucks—March.

Perlman Rim Corp., New York. Capital, $10,000,000—Demountable rims—March.

Covert Gear Co., Lockport, N. Y. Capital, $1,000,000—Trucks and tractors—April.

Union Tire & Rubber Co., St. Louis, Mo. Capital, $500,000—Tires—March.

Premier Motor Corp., Indianapolis, Ind. Capital, $2,500,000—Premier car—April.

Bournonville Motors Corp., New York. Bournonville rotary valve motors—April.

Day-Elder Motors Co., Newark, N .J. Capital, $100,000—Day-Elder trucks—April.

J. & D. Tire & Rubber Co., Charlotte, N. C. Capital, $500,000—J. & D. tires—April.

Kerosene Carbureter Co., Pittsburgh, Pa. Harroun kerosene carbureter—April.

Ohio Gas Generator Co., Columbus, Ohio. Webber kerosene vaporizer—April.

Warner Lens Co., Chicago, Ill. Warner glass lens—April.

United Motor Fuel Corp., New York. Capital, $25,000—Gasoline—April.

Essex Motor Truck Co., New York. Capital, $600,000—Ranier truck—June.

S. S. E. Co., Philadelphia, Pa. Capital, $5,000,000—S. S. E. car—June.

Comet Automobile Co., Rockford, Ill. Capital, $1,000,000—Comet car—June.

Higrade Motors Co., Buffalo, N. Y. Capital, $250,000—Higrade truck—June.

Gillette Motor Co., Mishawaka, Ind. Wilmo rotating sleeve motor—July.

Aland Motor Car Co., Detroit, Mich. Capital, $500,000—Aland car—July.

Nash Motors Co., Kenosha, Wis. Capital, $24,999,500—Jeffery car—July.

Enger Motor Car Co., Cincinnati, Ohio. Capital, $4,000,000—Enger car—Aug.

Phianna Motor Co., Newark, N. J. Capital, $500,000—Phianna car—Aug.

General Engineering Co., Detroit, Mich. Capital, $200,000—Doble steamer—Aug.

Metropolitan Motors, Inc., New York. Capital, $1,000,000—White Star truck—Aug.

Westgard Tire & Rubber Co., Warren, Ohio. Capital, $1,500,000—Westgard tire—Aug.

Parker Collapsible Rim Corp., Cleveland, Ohio. Capital, $500,000—Rims—Aug.

Iowa Rubber Tire Co., Davenport, Iowa. Capital, $1,000,000—Tires—Aug.

A. Howard Co., Galion, Ohio. Capital, $500,000—Howard car—Sept.

Auto Crank Shaft Corp., Detroit, Mich. Capital, $1,000,000—Crankshafts—Oct.

Kent Motors Corp., Newark, N. J. Kent car—Sept.

Budd Wheel Corp., Philadelphia, Pa. Capital, $2,000,000—Steel and wire wheels—Oct.

Union Products Co., Rockford, Ill. Capital, $200,000—Parts and accessories—Sept.

Eastern Motors Syndicate, Hartford, Conn. Charter Oak car—Oct.

Harroun Motor Corp., Detroit, Mich. Capital, $10,000,000—Harroun car—Sept.

Cook Attachment Patents, Inc., New York. Capital, $10,000—Issues licenses on Cook patents—Sept.

United Truck & Equipment Co., Detroit, Mich. Capital, $400,000—to operate United Motor Truck Co.—Oct.

Olympian Motors Co., Pontiac, Mich. Capital, $1,000,000—Olympian car—Oct.

Pilgrim Motor Co., Portland, Me. Capital, $750,000—Pilgrim car—Oct.

Emerson Motors Co., New York. Capital, $10,000,000—Emerson car—April.

Dey Electric Corp., New York. Steinmetz electric car—Nov.

Lozier Bros. Co., Cleveland, Ohio. Capital, $10,000,000—Automobiles—Nov.

Brunswick M. C. Co., Newark, N. J. Capital, $500,000—Brunswick car—Nov.

Sterling Automobile Mfg. Co., Bridgeport, Conn. Ams—Sterling car—Nov.

Winther Motor Truck Co., Kenosha, Wis. Capital, $330,000—Winther truck—Nov.

Ball & Ball Carbureter Co., Detroit, Mich. Capital, $20,000—Ball & Ball carbureter—Nov.

A. C. Axle Mfg. Co., Philadelphia, Pa. Csptal, $1,000,000—Compensating driving axle—Nov.

Electro-Pneumatic Gearshift Corp., Pittsburgh, Pa. Electro-pneumatic gearshift—Dec.

Duryea Motors, Inc., Wilkes-Barre, Pa. Capital, $4,000,000—Duryea Gem—Dec.

Rahan Co., Detroit, Mich. Capital, $100,000—Ford starters—Dec.

Refinancing

Stutz Motor Car Co. of America, Indianapolis, Ind. (old name Stutz Motor Car Co.). Capital, 125,000 shares, n.p.v.

Mitchell Motors Co., Racine, Wis. (old name Mitchell-Lewis Motor Co.). Capital, 125,000 shares, n.p.v.

Scripps-Booth Co., Detroit, Mich., reorganized. Capital, $1,000,000.

Portage Rubber Co., Barberton, Ohio. Capital increased from $1,250,000 to $3,000,000.

Stromberg Carbureter Co. of America, Chicago, Ill. (old name Stromberg Motor Devices Co.). Capital increased from $50,000 to $5,000,000.

Republic Motor Truck Co., Alma, Mich. Capital increased from $852,219.98 to $1,312,500.

Redden Motor Truck Co., Detroit, Mich. Recapitalized at $500,000.

Enger Motor Car Co., Cincinnati, Ohio (old name Frank J. Enger Co.). Capital, $4,000,000, divided into $1,000,000 7 per cent pref. and $3,000,000 common.

Alliance Tire Co., Alliance, Ohio. Capital increased from $150,000 to $650,000.

Pennsylvania Rubber Co., Jeannette, Pa. Reincorporated with capital of $6,000,000. Previous capital $2,000,000.

Polack Truck Tyre Corp., Bridgeport, Conn. (old name Polack Tyre & Rubber Co.). Capital, 100,000 shares, n.p.v.

Abbott Corporation, Detroit, Mich. (old name Consolidated Car Co.). Capital increased from $500,000 to $1,250,000.

Torbenson Axle Co., Cleveland, Ohio (old name Torbenson Gear & Axle Co.). Capital, $1,750,000, divided into $1,000,000 preferred and $750,000 common.

McFarlan Motor Corp., Connersville, Ind. (old name McFarlan Motor Co.). Capital, $3,000,000.

General Motors Corp., New York (old name General Motors Co.). Capital, $102,600,000, divided into $82,600,000 common and $20,000,000 non-voting preferred. Preferred is 6 per cent cumulative.

Winton Co., Cleveland, Ohio. Capital issue of $1,500,000 7 per cent cumulative preferred.

Gramm-Bernstein Motor Truck Co., Lima, Ohio (old name Gramm-Bernstein Co.). Capital, $4,000,000, divided into $3,000,000 common and $1,000000 preferred.

Firestone Tire & Rubber Co., Akron, Ohio. Sale of $5,000,000 new preferred at 6 per cent.

Star Rubber Co., Akron, Ohio, reorganized. Capital increased from $200,000 to $400,000 preferred.

Fisk Rubber Co., Chicopee Falls, Mass. Capital increased from $15,000,000 to $39,500,000. New capital, $7,500,000 first preferred, $5,000000 second preferred, $12,000,000 common.

Hydraulic Pressed Steel Co., Cleveland, Ohio. Issue of $1,000,000 7 per cent cumulative preferred.

National Motor Car & Vehicle Corp., Indianapolis, Ind. (old name National Motor Vehicle Co.). Capital, 53,000 shares at $42.50 per share.

Raybestos Co., Bridgeport, Conn. (old name Royal Equipment Co.). Capital, $1,500,000.

Manhattan Electrical Supply Co., New York (no change in name). Capital, $5,000,000. First preferred, $1,500,000, 7 per cent cumulative. Second preferred, $500,000, 7 per cent cumulative. Common, $3,000,000.

International Motor Truck Corp., New York (former name International Motors Co.). Capital, $7,372,790. 71,043 shares, p.v. $100. 53,638 shares n.p.v.

Pierce-Arrow Motor Car Corp., Buffalo, N. Y. (old name Pierce-Arrow Motor Car Co.). Capital, 100,000 shares 8 per cent convertible preferred. 250,000 shares of common, n.p.v.

Monitor Motor Car Co., Columbus, Ohio (old name Cummins-Monitor Co.). Capital, $10,000.

Emil Grossman Mfg. Corp., New York (no change in name). Capital, $320,000. First preferred, $150,000. Second preferred, $160,000. Common, 10,000 shares, n.p.v.

Smith Motor Truck Corp., Chicago, Ill. (old name Smith Form-A-Truck Co).. Capital, 20,000 shares of 8 per cent cumulative and convertible preferred; 1,200,000 shares of common, p.v. $10.

Duplex Truck Co., Lansing, Mich. (old name Duplex Power Car Co.). Capital, $1,000,000.

Empire Tire & Rubber Corp., Trenton, N. J. (old name Empire Rubber & Tire Corp.). Capital, $6,000,000. Preferred, $1,500,000 7 per cent cumulative convertible. Common, $4,500,000, common p.v. $10.

Knickerbocker Motors, New York (old name Knickerbocker Motor Truck Mfg. Co.). Capital, $500,000 all common, p.v. $10.

Kokomo Tire Co., Kokomo, Ind. (old name Kokomo Rubber Co.). Capital, 100,000 shares, n.p.v.

Four Wheel Drive Automobile Co., Clintonville, Wis. Capital increased from $250,000 to $500,000.

Kelsey Wheel Co., Detroit, Mich. Capital increased from $1,000,000 to $1,500,000.

Ogren Motor Works, Waukegan, Ill. (old name Ogren Motor Car Co.). Capital, $1,000,000, from $25,000.

Sparks-Withington Co., Jackson, Mich. Capital increased from $300,000 to $1,000,000.

M. & S. Gear Co., Detroit, Mich. Capital increased from $1,000,000 to $1,750,000.

Hurlburt Motor Truck Co., New York. Capital increased from $150,000 to $450,000. $350,000 7 per cent preferred; $100,000 common.

Lancaster Tire & Rubber Co., Lancaster, Ohio (old name Midgley Tire & Rubber Co.). Capital increased from $550,000 to $850,000.

Goodyear Tire & Rubber Co., Akron, Ohio. Capital increased to $50,000,000. $25,000,000 preferred; $25,000,000 common.

Packard Motor Car Co., Detroit, Mich. Capital increased to $21,000,000. Preferred, $8,000,000; common, $21,000,000.

Garford Motor Truck Co., Lima, Ohio. Cap-

ital increased to $5,000,000. Common, $2,500,000; preferred, $2,500,000.

Autocar Co., Ardmore, Pa. Capital increased from $300,000 to $1,800,000.

Auto Body Co., Lansing, Mich. Capital increased from $500,000 to $1,000,000.

Republic Motor Truck Co., Alma, Mich. Capital increased from $250,000 to $1,000,000.

Elgin Motor Car Corp., Chicago, Ill., Capital increased from $1,000,000 to $3,500,000.

McCord Mfg. Co., Detroit, Mich. Capital increased from $1,000,000 to $2,500,000.

Cadillac Auto Truck Co., Cadillac, Mich. Capital increased from $100,000 to $200,000.

Willys-Overland Co., Toledo, Ohio. Capital increased from $25,000,000 to $75,000,000. $50,000,000 common. $25,000,000 pref.

Wyman & Gordon Co., Worcester, Mass. (no change in name). Capital increased to $3,000,000.

Mergers

Motor Products Corp., Detroit, Mich.
Includes: Rands Mfg. Co., Detroit.

Vanguard Mfg. Co., Detroit.
Diamond Mfg. Co., Detroit.
Universal Metal Co., Detroit.
Superior Mfg. Co., Ann Arbor, Mich.
Capital—100,000 shares, n.p.v.

Fisher Body Corp., Detroit, Mich.
Includes: Fisher Body Co., Detroit.
Fisher Closed Body Co., Detroit.
Fisher Body Co. of Canada, Ltd., Walkerville, Ont.
Capital—$5,000,000 7 per cent cumulative pref. 200,000 shares, n.p.v.

Elgin Motor Car Corp., Chicago, Ill.
Includes: New Era Motor Car Co., Joliet, Ill.

Willys-Overland, Ltd., Toronto, Ont.
Includes: Willys-Overland of Canada, Toronto.
Russell Motor Car Co., Toronto.

Edmunds & Jones Corp., Detroit, Mich.
Includes: Edmunds & Jones Mfg. Co., Detroit.
Canadian Lamp & Stamping Co.
Chicago Electric Mfg. Co., Chicago.
Capital—$1,000,000 of 7 per cent pref.; 5000 shares of common.

Corcoran-Victor Co., Cincinnati, Ohio.
Includes: Corcoran Lamp Co., Cincinnati.
Victor Lamp Co., Cincinnati.
Victor Auto Parts Co., Cincinnati.
Capital—$2,250,000. $750,000 pref. $1,500,000 common.

United Motors Corp., New York.
Includes: Perlman Rim Corp., New York and Jackson, Mich.
Dayton Engineering Laboratories Co., Dayton, Ohio.
Remy Electric Co., Anderson, Ind.
Hyatt Roller Bearing Co., Newark, N. J.
New Departure Mfg. Co., Bristol, Conn.
Lovell-McConnell Mfg. Co., Newark, N. J.
Harrison Radiator Corp., Lockport, N. Y.
Houk Mfg. Co., Buffalo.
Brown-Lipe-Chapin Co., Syracuse, N. Y.
Capital—1,200,000 shares n.p.v.

Steel Products Co., Cleveland, Ohio.
Includes: Steel Products Co., Cleveland.
Michigan Electric Welding Co., Detroit.
Metals Welding Co., Cleveland.
Capital—$4,000,000.

Signal-Commerce Motor Truck Co., Detroit, Mich.
Includes: Signal Motor Truck Co., Detroit.
Commerce Motor Car Co., Detroit.
Capital—600,000 shares, n.p.v.

Kelsey Wheel Co., Detroit, Mich.

1916—A 100 M. P. H. Speed Era

All Records Broken—106.71 M. P. H. Reached—Three New Speedways—Resta Champion Driver

THE year 1916 will be recorded as a year of high speed contests on track and road. With tbe exception of the 300-mile race at Indianapolis, Decoration Day, when Resta's average was 83.99 m.p.h., as compared with 89.84 m.p.h., made by De Palma in 1915, all speedway records were broken. An average of 88.62 m.p.h. was recorded at all of the speedway races. In the fifteen championship award events an average speed of 92.45 m.p.h. was made. In ten of the speedway events this year, 100 m.p.h. or over was recorded. Whereas last year but seven drivers attained a speed of better than 100 m.p.h., 1916 saw twenty-one finishers with an average of better than 100 m.p.h. The fastest race of the year was the 20-mile Coney Island Cup Race, New York, on May 13, in which Aitken averaged 106.71 m.p.h. Aitken also has the honor of recording the long distance record of 105.95 m.p.h. for 100 miles, and 104.83 m.p.h. in the 250-mile Astor Cup Race, New York, Sept. 30. Both the Vanderbilt Cup and Grand Prize road races were featured by new records of 86.98 and 85.55 m.p.h., respectively.

498 Starters in 37 Events

This year there were 498 starters in tbe tbirty-seven races with 238 finishers. Last year 333 cars started in twenty-two races and 137 finished. Out of twenty-seven races on speedways, and including the Vanderbilt and Grand Prize road events, Aitken finished first in seven, Resta in six, De Palma in four, Rickenbacher in three, Wilcox three, and Mulford, D'Alene and Cooper, one each. D'Alene and Cooper took second tbree times eacb, and Hugbes, Milton, Lewis, Rickenbacher and Aitken each finished with two seconds to their credit. Lewis entered more races than any other driver, having participated in twenty-one events and placing in twelve. Rickenbacher entered nineteen races, took three firsts, two seconds, two thirds, one fourth and was unplaced in eleven. Resta enjoyed the distinction of winning every event in which he finished.

$243,781 in Prize Money

The distribution of prize money this year was lower than in 1915, a total of $243,781 being given in twenty-five of the main speedway events, and the two big road events, the Vanderbilt and Grand Prize. This compares with $282,000 in 1915. Of this total, Dario Resta, the champion driver of the year, received $44,400 in prize money, $5,000 of the Goodrich and $2,000 of the Bosch prize money and the $1,000 silver trophy of the latter. Aitken, who finished second in the championship award, received $30,206 in prize money. Rickenbacher was third with $20,050, wbile De Palma won $15,454 and D'Alene, $15,394. Tbese five were the only drivers to win in excess of $10,000. By winning fourteen firsts the Peugeot won first honors for the year. Three new speedways were opened in 1916 at Kansas City, Cincinnati, and Uniontown. The latter is a 1⅛-mile board track. The Kansas City speedway is a 1⅛-mile dirt track. Cincinnati opened a 2-mile board oval; and Uniontown, Pa., a 1⅛-mile board track.

Records in 1916 Speedway and Road Races

Barney Oldfield, driving the Christie, broke the speedway record in the Ventura trophy race on the Ascot speedway March 19, turning a lap in 45 sec. flat.

Bob Burman, driving a Peugeot, from a standing start, made a lap in 58 1/5 sec., which made a new record. This was also at the Ascot speedway, March 19.

John Aitken, driving a Peugeot, established a new world's record in the 20-mile event at Sheepshead Bay, May 13. His time was 11:15, or at an average speed of 106.71 m.p.h., lowering the record made by Resta on the same track in 1915, namely, 11:40.92.

R. R. Duff set amateur's speedway lap record of 94 m.p.h. on Chicago speedway, May 21.

Barney Oldfield, driving his Christie, circled the Chicago speedway in 1 min. 3¾ sec., or at 113 m.p.h.

Dario Resta set new record for Chicago speedway, June 11, his time being 3 hr. 2 min. 31.64 sec. for the 300-mile event, or at a speed of 98.61 m.p.h. Resta also broke the record made by Porporato last year for 100 miles, which was 1 hr. 28 sec., his time being 59 min. 34.7 sec. Resta bettered his time or 2 hr. 2 min. 17 sec. for 200 miles last year by a second.

June 10 Ralph De Palma established a new American record for distance covered in 1 hr., driving on a speedway track, when in the 60 min. he covered 93.72 miles. The record was made on the Chicago speedway between qualifying trials for the annual derby.

In a dual meet with Ralph De Palma at the Chicago speedway, June 18, Dario Resta established new American records for 10, 24 and 50 miles. His mark of 96 m.p.h. for the 50-mile broke the record of 88.87 m.p.h. set by Christiaens in 1914. The new records for the 10-mile and 24-mile are 102.5 and 105.1 m.p.h. respectively.

Harry Hurtz, driving a Houk Special, broke the mile record for cars under 231 cu. in. when he turned the mile oval at Ascot in 54 sec., June 27.

Harold Brinker, driving a Cadillac eight, July 4, lowered former record for 132-mile road race from Denver to Laramie, Wyo., by 33 min., his time being 2 hr. 55 min. 10 sec.

Dario Resta set record of 1 hr. 30 min. 43 sec. for 150 miles on 1¼-mile tracks at Omaha, July 15.

Eddie Rickenbacher, driving the Maxwell, broke the world's 25-mile record at Omaha, July 9, his time being 14:36.47, against 17:30.4, made by Oldfield at Indianapolis in 1914.

Dario Resta, driving the Peugeot, broke the world's 5-mile record at Omaha, July 9, his time being 2:44.82, against 3:11.75, made by Bragg at Los Angeles in 1912.

W. Rader, driving a Packard racing test car, fitted with a twelve-cylinder aviation engine, broke previous track record at Indianapolis, Aug. 2, turning the 2½-mile oval in 1:29:32, an average speed of 100 m.p.h.

Aitken broke world's 250-mile record at Sheepshead Bay, Sept. 30, driving a Peugeot at an average speed of 104.83 m.p.h. The previous record was made by Resta on the Chicago speedway, namely, 2:33:31/16.

In October Ralph De Palma was granted an official 50-mile speedway record for his performance on the Omaha 1¼-mile track, his time being 29:02.47, or at a speed of 103.45 m.p.h. The previous record was held by Resta with a time of 81:57.40.

Aitken broke 100-mile record at Sheepshead Bay, Oct. 28, driving a Peugeot at an average speed of 105.95 m.p.h.

A new record for the grand prize race was set at Santa Monica, Nov. 18, when a Peugeot, piloted twenty laps of the 8.04-mile course by Howard Wilcox and the remaining twenty-eight by Aitken, won the race in 4:42:47, or at an average speed of 85.59 m.p.h., lowering the former record of 77.20 m.p.h. made by Pullen in 1914.

A. H. Patterson, driving a Hudson super-six, set a new world's record for non-stop road race of 403 miles at an average of 78.13 m.p.h. at Santa Monica, Nov. 18.

In the Vanderbilt Cup race at Santa Monica, Nov. 16, Dario Resta established an average of 86.9897 m.p.h. for 294.0355 miles, or thirty-five laps of the 8.041-mile circuit, a new record for both the Vanderbilt and the Santa Monica course over which Tetzlaff in 1912 averaged 78.72 m.p.h. for 302 miles.

Factory Additions Total 9,362,881 Square Feet in 1916

Partial Returns Show Large Expansion in All Branches of Manufacture—Additions and New Equipment Cost $17,682,255

PARTIAL, though fairly complete, returns in a census conducted by THE AUTOMOBILE throughout all branches of the automobile, motor truck, accessory and allied industries show that during the year 1916 nearly 10,000,000 sq. ft. were added to factories at a cost of approximately $10,000,000, while new machine equipment, etc., added during the year amounted to over $8,000,000. Although complete cost figures are not available, the total outlay for enlarged and improved manufacturing facilities, as indicated by the census returns, represents a total of over $20,000,000, the exact amount of expenditures given being $17,682,265.

Last year the extent of floorspace added was slightly larger according to the partial returns made in the census conducted at that time, giving a total of 11,142,508 sq. ft. for the 12 months of 1915. However, the expenditures for these additions last year total only $8,251,755, or over $1,000,000 less than was expended by manufacturers during 1916 for additional floorspace. Moreover, the expenditure for new equipment last year was only $4,770,590, only a little more than half of the outlay during 1916 when $8,233,190 was devoted to this purpose. As indicated by last year's returns the total cost of increased factory facilities was $12,886,342, as compared with $17,682,255.

These figures are so tremendous in themselves that they do not convey a full understanding of the enormous expansion which has characterized the industry during the past 12 months. To bring this out a little more strongly a few graphic illustrations may be of value. For example, if the entire extent of the floorspace added to automobile, truck and accessory factories this year were to be contained in a single one-story building 100 ft. wide, this would be nearly 18 miles in length. To give an idea of the magnitude of the sums expended for increased factory facilities this year, if the $9,449,065, which went for factory additions, were converted into silver dollars and piled one on top of another, the column would reach over 18 miles in height. As for the $8,233,190 in added equipment, if this were treated in the same manner it would attain a height of 16 miles, so that the total expenditure, if it could be imagined in such a form, would represent a column 34 miles high. If paper dollars were used and placed end to end, the $17,682,255 would form a band about 2040 miles in length, or over twice the distance from New York to Chicago and two-thirds of the distance across the United States from coast to coast.

Many Large Additions

Taking up the additions made by the automobile manufacturers, 3,775,776 sq. ft. were added by forty-one companies at a cost of $2,312,000, and equipment representing an outlay of $1,321,023 brought the total expenditure up to $3,633,023. Willys-Overland added half a million square feet, as did Apperson; Hudson added 484,392; Haynes 350,000; Velie 200,000, and Reo 176,294. Unfortunately cost statistics for a number of the largest additions are not available so that the total is far lower than it should be. Similarly in numerous other cases the cost of the additions is given, but the number of square feet of floorspace added is not furnished, so that it can be easily seen that this total is also below its actual value. Of the expenditures cited in the table herewith the $386,000 spent by Premier on new equipment for its large factory is of interest. Apperson's new factory group cost $300,000 and Briscoe's addition $250,000, with another $200,000 expended for equipment. Haynes spent a round half million, equally divided between factory additions and new equipment; and White paid $200,000 for enlarged manufacturing room.

Truck Makers Expand Plants

In the commercial vehicle field large additions have been made in many factories which failed to send in returns, but the total of 278,017 sq. ft. added by some twenty concerns is a fair indication of the marked expansion taking place throughout the entire industry. These additions were made at an expense of considerably more than the $150,000 given in the returns, as will be noted by referring to the numerous blank spaces in this column of the tabulation. In the way of added equipment the returns were a little more complete, making a total of $272,500, the largest item of which is the $75,000 spent by the H. J. Koehler Motors Corp. The largest increase of factory space in this division, according to the returns, has been made by the Gramm-Bernstein Motor Truck Co., which is credited with the addition of 75,000 sq. ft. constructed at a cost of $27,000. This company also expended $70,000 for new equipment, making the total expenditure for the purpose of increasing and facilitating production $97,000. Other truck manufacturers who have made notable additions to their factory and equipment during the year are: Kleiber & Co., Inc., 46,000 sq. ft., costing $75,000; Cadillac Auto Truck Co., 33,792 sq. ft., and Republic Motor Truck Co., 30,000 sq. ft.

Tractor and trailer companies have increased their facilities as might be expected from the development of their respective fields during 1916. Reports from only three tractor manufacturers show 28,000 sq. ft. added at a cost of $251,000, an expenditure of $108,500 bringing the total for these three concerns alone to $359,500.

Engine Builders Increase Facilities

Nine engine manufacturers report 406,740 sq. ft. of additional floorspace during the past 12 months, partial returns showing the additions of only five concerns cost $247,000 and the new equipment increased this expenditure by eight concerns to $1,033,000, the equipment installed by these companies during the year amounting to $786,000.

Axle makers added 74,600 sq. ft. and $166,000 of new equipment and the carbureter manufacturers, although recording only 18,600 sq. ft. of additional floorspace, spent $106,000 for new machinery, etc. Bearing makers added 81,200 sq. ft., this including reports from only two companies, the U. S. Ball Bearing Mfg. Co. spending $160,000 for 80,000 sq. ft. Four bearing makers added $321,000 worth of new equipment.

In the body field three companies added over 100,000 sq. ft., the Auto Body Co., Dayton Body Co. and W. S. Seaman Co. In this division 494,588 sq. ft. of floorspace was added by thirteen companies, total expenditures for buildings and equipment being $570,800.

The largest addition reported by wheel manufacturing

concerns is that of W. K. Prudden & Co., which spent $250,000 in securing 185,000 sq. ft. Ten companies added 319,230 sq. ft. and $289,000 worth of new machinery at a total expenditure of $695,700.

Tire makers added nearly a million sq. ft. during the year, the total for nineteen companies being 914,400 sq. ft., costing $2,195,000, the $621,100 worth of additional machinery bringing the total spent to $2,816,100.

Parts makers added nearly as much space as the tire manufacturers, the total for thirty-five companies being 767,165 sq. ft. costing $930,000, while they spent twice as much for new equipment as reported by the tire factories, the $1,305,000 expended for this making the total expenditu parts makers $2,235,000.

The accessory field naturally reports the largest incr in all respects, adding 2,201,565 sq. ft., the cost figures given totaling $2,350,865, and the $2,722,767 spent for added equipment makes the total outlay for expansion as reported by 134 concerns in this branch of the industry $5,073,632. Some of the largest items which might be mentioned are the 375,000 sq. ft. added by Stewart-Warner and costing with equipment $885,000; 180,500 sq. ft. added by Prest-OLite; 130,000 by Bosch and 120,650 added by the American Auto Trimming Company.

A Summary of the Principal Factory Additions

Cost of New Facilities, Including Additional Equipment Required by the Industry in 1916

AUTOMOBILES

Company	Space Added Sq. Ft.	Cost of Additions	Added Equipment	Total Cost
Alter Motor Car Co	51,600	$45,000	....	$45,000

Automobile Chronology for 1916

Important Developments in the Industrial and Financial Fields Arranged According to Date of Occurrence

JANUARY

1—Kentucky Wagon Co., Louisville, to assemble cars for the Dixie Motor Car Co.
1—Pfau Mfg. Co., Cincinnati enters automobile field with output of brass specialities.
1—American Rotary Valve Co., Anderson, Ind., discontinues the manufacture of electric motors.
2—Avery Farm Implement Co., Peoria, Ill., to make $295 tractor.
3—Auto Parts Mfg. Co., Milwaukee, reorganizes and absorbs Badger Specialties Mfg. Co.
3—With more than 22,000 miles to its credit, the Maxwell car, in non-stop run started Nov. 22, was stopped Jan. 3 after 44½ days' test. Road records are: 5000 miles in 10 days; 10,000 miles in 20 days; 12,405 miles in 25 days; and 20,000 miles in 30 days.
4—U. S. district court judge signs final decree in Austin-Cadillac two-speed axle case, decision on which was rendered a year ago, granting Austin an injunction and damages against Cadillac.
4—Kelly-Springfield Tire raises 7½ to 26 per cent.
4—Overland reduces price of larger four $55, from $750 to $695.
10—National Automobile Chamber of Commerce cross-licensing agreement in force and includes agreement on exchange of shop right on patents and members.
10—National Acme Mfg. Co., Cleveland, acquires the business and plant of the Windsor Machine Co., Windsor, Vt.
12—Empire, Fails, Globe and Pennsylvania tire companies increase prices 10 to 25 per cent.
14—McClurg Rubber Co., Coshocton, Ohio, takes over S. & M. Tire & Rubber Co.
14—Lion Tire & Rubber Co., Lafayette, Ind., formed with a capital of $150,000, to manufacture tires. Purchases Heinze plant in Lafayette.
15—Fritchie Automobile & Battery Co., Denver, brings out a gas-electric car, with one electric unit and a four-cylinder motor.
15—Entz patents controlled by six members representing General Electric and Owen Magnetic companies.
17—Moline Plow Co., Freeport, Ill., to manufacture the Stephens six-cylinder automobile.
17—Randall-Faichney Co., Boston, reorganized. Management takes over assets of old one.
18—Gasoline 22 cents wholesale in New York City.
24—Stutz Motor Car Co., Indianapolis, doubles plant.
24—Vesta Accumulator Co., Chicago, brings out electric transmission.
25—Gasoline selling at 29 cents in New York.
29—Chevrolet - General Motors syndicate offers for exchange five shares of Chevrolet stock for one of General Motors. Voting trust formed.
29—Stock offer of Chevrolet-G. M. Syndicate changed to four shares of Chevrolet for one General Motors.
30—12,000 carloads of automobiles shipped in January.
30—Woods Motor Vehicle Co., Chicago, to build a gas-electric car at $2,700.
31—Ford produced 44,365 cars in January, second largest month. In April, 1915, produced 46,510.

FEBRUARY

7—Carter Carbureter Co., St. Louis, forms sales department. Cancels selling arrangements with H. W. Johns-Manville Co., to market its products direct.
11—Chalmers Motor Co., Detroit, arranges with Agricultural Credit Co., Chicago, for time payment service for dealers.
11—Studebaker arranges through Commercial Investment Trust, New York, for time payments.
14—General Electric Co. raises prices of Genemotor $10 to $85. Takes out license to manufacture under Coleman starter patents, Nos. 745,157 and 842,827.
15—U. S. circuit court of appeals confirms decision of district court judge, who declared the Perlman demountable rim patent valid and infringed by the Standard Welding Co.
17—Value of automobile output increases 350.3 per cent between 1909 and 1914. Government statistics show value of output in 1914 was 181.7 per cent greater than 5 years before.
17—Toledo, second largest automobile city. Cars numbering 95,650 left its factories in 1915. One thousand electric systems and 25,000 spark plugs per day produced there.
18—Briscoe Motor Co., Jackson, to absorb Jackson Motor Shaft Co., in July.
21—Buick prices advanced $35. Roadster at $985 and touring car at $1,020.
21—Bimel Buggy Co., Sidney, Ohio, reincorporates as Bimel Automobile Co.
24—Thomas B. Jeffery Co. increases wages 10 per cent and reduces working hours to 50 a week for day and 55 for night work.
29—Kardo Axle suit reopened. Ohio court of appeals upholds company's validity and orders rehearing.

MARCH

2—Champion Spark Plug Co., Toledo, increases output to 100,000 spark plugs daily. Former production 45,000 daily.
2—Sparks-Withington Co., maker of Sparton horns, wins patent battle through reversal of a United States district court decision issued in suit of Lovell-McConnell Mfg. Co., maker of Klaxon horns, against Oriental Rubber Supply Co., dealer in Sparton horns. No infringement on patent of Klaxon company was admitted, as patent was declared invalid.
2—Federal court of appeals reverses decision that dismissed axle patent infringement suit brought by the Kardo Co. against H. J. Adams.
3—New York gasoline reaches 24 cents a gallon, wholesale. Owners paying from 26 to 31 cents a gallon. Were paying from 14 to 17 cents year ago.
4—Studebaker Corp. raises prices of five models. In four-cylinder class, three-passenger roadster, $825 to $850; seven-passenger touring car, $845 to $875; landau-roadster, $1,145 to $1,150. Of six-cylinder models, three-passenger touring car, $1,025 to $1,060, and seven-passenger touring car, $1,050 to $1,085.
4—Pierce-Arrow Motor Car Co. plant in Buffalo closed, owing to strike of machinists. Six thousand men out.
6—Maibohm roadster at $595 is product of Maibohm Motors Co., Racine, Wis.
6—Automobiles, trucks and parts rank fifth in exports. Gained 232 per cent in 1915, to $111,180,139. Iron and steel first, with $338,703,720.
7—Locomobile Co. of America changes truck name to Riker.
8—Injunction against Standard Welding Co., Cleveland, prohibiting manufacture and sale of demountable rims, held to infringe Perlman patent No. 1,052,270, filed June 29, 1906.
8—Arbenz Car Co., Chillicothe, Ohio, taken over by National United Service Co., New York.
8—Resulting from suit of Louis H. Perlman against Standard Welding Co., charging infringement of Perlman's basic patent on demountable rim, injunction is issued against Standard Welding Co., prohibiting manufacture and sale by this company of such rims.
12—Plants of H. J. Walker Co. and Briggs Mfg. Co., Detroit, moved to Cleveland, to handle Chandler body work.
12—Chalmers Motor Co. ships $3,000,000 of cars in February. Biggest day was Feb. 29, when 198 cars were shipped.
16—Cadillac Motor Car Co. ships 25,000 Cadillac eights since company commenced manufacturing model in October, 1914.
17—H. J. Koehler S. G. Co., Newark, N. J., raises price of truck from $940 to $955.
18—Saxon Motor Car Corp. raises price of roadster and touring car from $785 to 815.
18—Willys-Overland Co. ships 27,685 Overland and Willys-Knight cars in first 2 months of 1916, as against 10,240 for same period in 1915. During January, 1916, 12,393 cars left factory, as compared with 4613 for the same month of 1915.
20—Wyman & Gordon Co., Worcester, Mass., reorganized with a capital of $3,000,000, and name changed to Wyman-Gordon Co.
20—Studebaker Corp., Detroit, increases output from 300 a day to 400.
21—Great Britain bars automobile imports.
21—Perlman Rim Corp., New York, secures two plants for manufacture of demountable rims.
21—Warner Auto Trailer Co., Beloit, Wis., to make trailers.
21—Nordyke & Marmon Co. increases price $200, bringing five-passenger model to $2,900 and seven-passenger car and three and four-passenger roadster to $2,950.
21—Solid tire suit ends. Court of Appeals affirms $210,000 judgment in favor of Kelly-Springfield Tire Co. against Diamond Rubber Co., on Grant patent No. 554,675, issued Feb. 18, 1896. Litigation has extended over period of 20 years.
23—F. B. Stearns Co., Cleveland, advances prices $50.
23—Pierce-Arrow Motor Car Co., Buffalo, increases wages 10 per cent.
27—Kemco Electrical Mfg. Co., Cleveland, reorganized.
28—Briscoe Motor Corp., Jackson, Mich., disposes of Argo Motor Co. plant in Jackson to Mansell Hackett.

APRIL

1—Michigan supreme court reverses decision awarding $20,000 damages to W. A. Paul, who claimed he invented curtain holder for inside curtains of automobile s, in a case against J. N. Collins, J. A. Bennett and the Novelty Leather Works, Jackson, Mich.
1—Overland ships 47,465 cars in three months. Comes within 1,000 cars of equalling entire yearly output of 1914. Output in March was 19,780, compared with 7,005 in March, 1915.
1—Jordan Motor Car Co. to build $50,000 plant in Cleveland.
1—Guaranty Securities Corp., New York, formed to finance time sales of automobiles.
3—Chalmers advances prices on touring car and cabriolet $40, roadster $20. Pathfinder raises price $275. Anderson Electric raises price $100.
3—Splitdorf Electrical Co., Newark, raises price of Splitdorf-Apelco electric starting and lighting system $10.
3—S. F. Bowser Oil Tank & Pump Co., Fort Wayne, Ind., pays 6 per cent dividend to employees on February wages.
4—Ford builds 58,329 cars in March, 14,450 better than March, 1915. Average daily output was 2,243 cars.
5—Perlman Rim Corp. purchases entire capital stock of Jackson Rim Co., Jackson, Mich.
6—Bock Bearing Co., Toledo, reorganized and name changed to Bock Taper Roller Bearing Co.
6—Great Britain places a treble tax on all British automobiles, ranging from $21 to $630, according to horsepower. Doubles tax on automobiles 16 hp. or less and trebles on cars over 16 hp.
8—Detroit, Toledo, Flint, Jackson and Lansing build 328,366 cars in first three months of 1916. Detroit plants produce 238,076 cars. Production in 1915 for these cities was 106,000 cars.
8—Auburn Automobile Co. advances price of 6-38 from $1,050 to $1,085. Lozier four advanced $100.

10—A Hudson super-six negotiated 1 mile in 35.12 sec. on the Ormond-Daytona beach. Five other trials were under 30 sec.
10—Champion Spark Plug Co., Toledo, produces 1,111,623 spark plugs in March.
12—Automobile industry represents 28 per cent of capital in Detroit manufacturing. U. S. Census statistics for 1914 show 120 concerns making cars, trucks, bodies and parts. Produce 40 per cent of value of all manufactures in that city.
14—Mitchell prices increased $75 for the five and three passenger car.
15—Winton prices raised $200.
16—McFarlan increases prices $210.
17—Studebaker Corp. institutes service policy to increase fuel efficiency.
21—Sears-Cross lowers prices on speedometers $4.
21—Overland wages raised 4 to 10 per cent with a reduced schedule of hours.
24—Briscoe raises prices $40 on 4-24, $35 on 4-38, and $35 on eight.
24—Argo raises prices $20.
24—Monroe Motor Co. turns over Flint plant to General Motors Co. and takes possession of plants formerly occupied by Welch Motor Car Co., Pontiac. W. C. Durant severs connection with Monroe concern.
25—Murray Motor Car Co., Pittsburgh, formed to manufacture cars.

MAY

1—Davis Motor Car Co. takes over Richmond, Ind., plant of Westcott Motor Car Co., which moves to Springfield, Ohio, occupying the plant of the Buckeye division of the American Seeding Machine Co.
1—Brunswick-Balke-Collender Co., Muskegon, Mich., maker of billiard tables, to enter automobile tire manufacturing field.
2—Rittman gasoline patent assigned to the U. S. Government.
2—Doehler Die-Casting Co., Brooklyn, N. Y., acquires controlling interest in American Die Casting Co., Newark, N. J., which will be named Doehler Die-Casting Co. of New Jersey.
2—Ralph Mulford, driving Hudson super-six stock chassis at Sheepshead Bay, breaks all previous 24-hr. records, averaging 75.8 m.p.h. for 1819 miles. The world's record of 65.905 m.p.h made by Edge, who drove 1581 miles 1310 yards, at Brooklands in 1907; the stock chassis record made by Mulford and Patschke in a Lozier at Brighton Beach in 1909, 1196 miles; the non-stock dirt track record made by Patschke at Brighton Beach in a Stearns in 1910, 1253 miles; the non-stock speedway record made by Virbeck and Hirsch at Los Angeles in 1911, 1491 miles, were the previous records.
2—Goodyear Tire and Rubber Co. suit against Firestone Tire and Rubber Co., in which it was held that the latter's tire-making machines infringed the patents held by the Goodyear company, was decided in favor of the Goodyear company.
6—Allen Motor Co., Fostoria, Ohio, shortens working day to 8 hr.
8—Boston Artificial Leather Co., New York, changed name to Zapon Leather Cloth Co.
8—Ford production in April, 51,739 cars, as compared with 46,510 in April, 1915.
8—Studebaker Corp. ships 490 cars on April 29. Biggest single day's shipment of company.
8—First Stephens car made by Moline Plow Co. Freeport, completed.
8—Sparks-Withington Co., American Gear Co., and Argo Motor Co., all of Jackson, Mich., shorten working hours and pay same wages as before.
8—Willys-Overland Co. completes addition, adding 500,000 sq. ft., and bringing entire plant to 103 acres. Shipments average 900 cars a day.
9—Grant Motor Car Co., Findlay, Ohio, to move to Cleveland.
12—Willys-Overland sales gain 174 per cent in year ending April 30. Shipped 137,665 cars as compared with 50,258 in preceding period.
12—Packard acquires Krit plant in Detroit.
12—Standard Steel Tube Co., Toledo, Garford Mfg. Co. and Fisk Rubber Co. reduce working day to 8 hr. with increased pay.
13—Studebaker Corp. sells 16,952 cars in first quarter of 1916, as compared with 9,400 the corresponding period in 1915.
13—Pennsylvania Rubber Co. reduces price on Vacuum Cup and Ebony Tread tires $2 to $6.
15—France prohibits importation from the United States and England of automobile chassis.
17—E. G. Baker, driving Cadillac eight, crosses continent in 7 days 11 hr. 52 min.
20—American Automobile Assn. in favor of singe car tax. Advocates Adamson bill.
27—Flat Automobile Works locates factory in Budapest, Hungary. Factory situated at Kelenfold, in suburbs of Budapest, has been rented.

JUNE

9—Hanlon windshield patent declared invalid. Cases involved: Rauch & Lang Carriage Co. vs. W. H. Hanlon, J. R. Wardrop and Anoerson Electric Car Co., and National Automobile Chamber of Commerce vs. W. B. Hanlon and J. R. Wardrop and Anderson Electric Car Co.
9—Hanlon windshield patent invalid. Injunction against N. A. C. C. members on use of windshield to be lifted. Involved patent No. 13,653, issued to W. B. Hanlon on Dec. 2, 1913.
13—National Automobile Chamber of Commerce approves service and repair parts policies; defines standard truck.
14—Monster $250,000,000 merger abandoned. Included Willys-Overland, Hudson, Chalmers and Fisk.
15—Litigation between the Universal Rim Co. and the Standard Welding Co. settled out of court, the Standard Welding Co. acknowledging validity of patents by paying back royalties and taking out 10-year license under patents.
27—French Government places 70 per cent duty on imports.
29—King eight covers 11,000 miles in 2 weeks in June on non-engine stop test, maintaining an average of over 32 m.p.h.

JULY.

8—U. S. Government receives bids on 2,000 trucks and 400 passenger cars for Mexico service.
10—Results of Saxon 300-mile non-stop test conducted in all parts of country show 206 cars traveled 61,800 miles, and grand average was 23.5 m.p.g. of gasoline and 175 miles to a quart of oil.
12—France lowers truck duty and admits American trucks on pre-war tariff, equivalent to 12 per cent of value. Passenger cars, however, 70 per cent import duty.
14—U. S. district court holds that no infringement of patent was present in the manufacture of the Eclipse-Bendix transmission drive by the Eclipse Machine Co. Suit was brought by the Bijur Motor Lighting Co. against Eclipse Machine Co. and Vincent Bendix.
14—Neville Steering Wheel & Mfg. Co., Detroit, absorbs Neville More-Room Steering Wheel Co.
14—Court rules Eclipse Machine Co., Elmira, N. Y., and Vicent Bendix, Chicago, entitled to Bijur license on starting motor gear.
14—C. W. Nash, retiring president of General Motors Co., together with Lee, Higginson & Co., purchase entire stock of Thomas B. Jeffery Co., Kenosha, Wis. Purchase price about $9,000,000.
20—United States automobile makers produce 754,902 passenger cars in first six months of 1916. Ninety-nine factories contribute; 96 per cent made in Michigan, Ohio and Indiana; Ford alone makes 298,900, Overland 94,477, others over 40,000.
20—Ford Motor Co. adds thirty-four branches.
20—England has standard truck design. Other countries standardize both cars and aviation engines.
22—Forty-three Saxon cars, racing in relays, establish a transcontinental relay record, arriving at San Francisco July 22, 6 days 18 hr. 10 min. after leaving New York. Average speed was about 25 m.p.h.
29—Marmon stock car, driven by S. B. Stevens, Walter Bleiling, Robert Creighton, William Binz and Fred Barbour, cross the continent in 5 days 18½ hr., leaving New York July 23.

AUGUST.

1—Pathfinder twin six crosses continent on high gear, leaving San Diego July 3 and reaching New York Aug. 1. Seals by A. A. A. No attempt at speed record; average daily of 200 miles; total mileage 4921; 4 days no running; gasoline consumption 10.2 m.p.g.
5—Republic Motor Truck Co., Alma, Mich., adopts bonus system in plant.
7—Ford builds 533,921 cars in one year. Makes 225,708 more in 1916 than in 1915. Cars worth $235,000,000. Employs 31,035 men.
14—Ford drops retail sales.
15—Stewart-Warner Speedometer Co., Chicago, purchases the V-Ray Co., Marshalltown, Ia.
15—Chevrolet produced 54,700 cars during fiscal year ending Aug. 1.
15—Ford introduces new body styles.
21—Saxon employees get bonus ranging from 3 to 6 per cent of their yearly salaries.
21—Timken-David Brown Co., Detroit, purchased by the Timken-Detroit Co., and the manufacturing operations consolidated under the management of the axle company.
22—Fuel tests made by 200 representatives of Master carbureter show mileages such as 31.7 m.p.g. in Phoenix; 28, Boston; 24, Tulsa; 22.4, Salt Lake City; 22.3, Los Angeles; and 22, Denver.

SEPTEMBER.

5—Maxwell builds 532 cars in one day. Average production 400 cars daily.
24—Hudson super-six, driven by A. H. Patterson, Ralph Mulford and C. H. Vincent, crosses continent in 5 days 3 hr. 31 min., breaking transcontinetal for the third time in year.
26—Goodyear starts new plan for retailing its tires. Number of dealers reduced. No exclusive territory.

OCTOBER.

2—Automobile industry gains 153 per cent in five years; 1909-1914 value of products is $632,831,000; gain, $383,629,000.
10—Ford car equipped with a Myle-Maker carbureter attachment, with top and windshield up and four passengers, makes 26.6 m.p.g. in test in Chicago.

NOVEMBER.

2—Truck output in 1916 is 58,000 for first six months.
2—Fisher Body Corp., Detroit, buys one of plants of the Regal Motor Car Co., Detroit.
3—Injunction holds up Ford profits. Dodge Bros. in suit seek to prevent investment of surplus money.
14—Bankers secure control of Hess-Bright Mfg. Co., Philadelphia.
20—Carl G. Fisher to build one-wheel tractor in Indianapolis.
21—Knight Tire & Rubber Co., Canton, Ohio, absorbed by Fabricord Tire Co.
20—Discher patent covering bumper bracket construction is held valid and infringed by the Auto Parts Mfg. Co., and a permanent injunction granted to the Gemco Mfg. Co. Verdict is by U. S. district court.
21—Springfield Body Corp. files suit against Fisher Body Corp., the Fisher company and Fred J. Fisher and Louis Mendelsohn, charging infringement of design of patents on Springfield-type body.
28—U. S. Wheel Corp., Chicago, Ill., formed to manufacture Baker pressed steel wheel.

DECEMBER.

1—Moto-Meter Co., Inc., New York, gets temporary injunction to stop Heat-Ometer Co. from making and selling Heat-Ometer and from using the word "Heat-Ometer," which was held an infringement on the trademark "Moto-Meter."
2—Cadillac Motor Car Co. sues Cadillac Auto Truck Co., asking that latter firm be restrained from use of name "Cadillac," "Cadillac Auto Truck Co.," or other name prejudicial to the interest of the Detroit company.
4—Any State may tax non-residents decided by United States Supreme Court in case of New Jersey vs. F. J. Kane. N. J. motor laws upheld.
8—Prest-O-Lite Co. awarded $3,541.45 damages by judgment in suit brought against Camille Bournonville and Ida Bournonville, Newark, N. J., for refilling and sale of Prest-O-Lite tanks and substitution of refilled tanks.
11—Ford Motor Co. wins decision against Stahlbrodt Co., Rochester, N. Y., holder of patent purporting to cover a certain type of windshield commonly known as zig-zag windshield in U. S. circuit court of appeals, decision reversing prior ruling of lower court.
11—United States Army to have caterpillar tractors similar to those used in British army.
12—Ajax Rubber Co., Trenton, purchases Racine Rubber Co., Racine, Wis. Ajax capital increased.
13—Argentine Mercantile Corp., New York, formed to facilitate Argentine shipments. For co-operative trade in non-competing lines.

Financial

JANUARY.

6—Portage Rubber Co., Barberton, Ohio, shows profits of $129,000 for 1915, an increase of 46⅓ per cent. Sales amounted to $1,100,000, or 62½ per cent over 1914.

14—Ford Motor Co. of Canada makes $3,202,000 in 1915. Produced 24,500 cars. Plans 40,000 for 1916.

14—Ogren Motor Car Co. changes name to Ogren Motor Works. Capital raised from $25,000 to $1,000,000. Plans production of 3,000 cars for 1916.

15—Signal Motor Truck Co., Detroit, increases capital $85,000 to $450,000, composed of $300,000 common and $150,000 7 per cent cumulative preferred.

19—Springfield Body Corp. offers $750,000 8 per cent cumulative preferred to finance new Detroit plant.

25—Grant Motor Car Co., Findlay, Ohio, raises capital from $200,000 to $4,000,000, composed of $3,000,000 common and $1,000,000 7 per cent preferred. Earned in 1914 about $165,000. Shipped 4,000 cars.

29—Goodrich surplus $10,305,679, equal to 17.17 on common. Net sales during 1915 total $55,416,866, a gain of 32½ per cent.

FEBRUARY.

5—Spiitdorf Electrical Co., Newark, N. J., shows profits in 1915 of $745,107, or 16 per cent on the $4,393,000 capital stock. Profits in 1914 were $388,921.

8—Briscoe offers $1,500,000 7 per cent cumulative preferred for subscription.

15—Continental Motor Mfg. Co., Detroit, declares 100 per cent stock dividend. Capital increased from $2,900,000 to $5,900,000.

17—Fisk Rubber Co. sales total $14,500,000 in 1915. Net profits total $1,791,579.

26—Studebaker net profits equal $9,067,425 in 1915. Sales total $56,539,006, a gain of $13,094,782. Sells 46,845 cars. Earns $8,236,980, equal to 29.5 per cent on the common.

24—Chandler Motor Car Co. profits total $933,217 for 1915, as against $321,821 in 1914. Has $1,613,515 in bank.

24—Pennsylvania Rubber Co. reports a $4,000,000 business for 1915.

MARCH.

4—Fisk Rubber Co., Chicopee Falls, Mass., has net profits of $1,791,579 in 1915, against $942,204 in 1914.

7—Chevrolet Motor Co. earns $1,653,686 in 4½ months ended Dec. 31, 1915. Cash in hand is $5,377,079. Produced 11,888 cars in that period.

8—Peerless Truck & Motor Corp., profits on trucks for 1915 total $2,555,773, equal to 22½ per cent on the capital stock.

8—U. S. Rubber Co. profits total $11,486,705 in 1915 as against $9,776,873 in 1914. Net sales for 1915 total $92,861,015 as against $83,678,812 in 1914. Has surplus of $2,882,048 as against $721,951 in 1914.

13—Willys-Overland shows income in 1915 of $9,870,678. Earns over 46 per cent on the $21,000,000 common. Profit and loss surplus $14,720,550 as against $7,651,931 in 1914.

18—Electric Storage Battery Co., Philadelphia, has income in 1915 of $1,360,748, equal to 8.37 per cent on $16,249,425 capital, compared with $1,103,237 in 1914, equal to 6.78 per cent on $16,250,000 stock. Surplus after payment of dividend totalled $710,784, as against $453,273 in 1914. Gross sales were $1,770,188 as against $1,395,793 in 1914.

18—M. & S. Gear Co., Detroit, maker of M. & S. differential, increases capital from $1,000,000 to $1,750,000.

18—White Motor Co., Cleveland, declares initial dividend of 1¾ per cent on $16,000,000 stock, placing stock on 7 per cent basis.

APRIL.

22—Goodyear issues $10,000,000 of new preferred to take care of increased output. To produce 25,000 tires a day.

JUNE.

26—Paige-Detroit earnings at rate of $1,500,000 per annum, or 150 per cent on the stock. Tangible assets are $1,504,497, or $15 per $10 share.

JULY.

10—Hupp Motor Car Corp. business increases 47.3 per cent over 1915. Employees increase 74.6 per cent.

20—$1,275,000 profit for Stewart-Warner Speedometer Co., Chicago, during six months ending June 30.

1—Willys-Overland Co., Toledo, earns $4,377,799 in four months ending April 30, 1916. Surplus is $4,193,144.

23—Packard earns $18,636,506 in seven years. Over $9,000,000 charged off for depreciation. Earnings for nine months of fiscal year amount to $6,050,000 as compared with $2,769,518 for 1914 and 1915.

AUGUST.

3—Chalmers assets increased 50 per cent in past year. Gained from $4,857,274 to $13,051,538. Surplus totalled $3,066,673 as against $1,010,422 in 1915.

1—General Motors Co. earned in 11 months ending June 30, $144,000,000 as against $86,000,000 in same period in 1915. Sold 121,133 cars in that period as against 68,604 in same period in 1915.

2—Studebaker earned $6,028,329 in six months ending June 30. Included $180,000 war profits. Common on 10 per cent basis. During the corresponding period in 1915 corporation's profits amounted to $5,774,074, including nearly $3,000,000 of war order profits.

SEPTEMBER.

4—Ford profits in fiscal year ending July 31 were $59,994,118. Had $100,000,000 surplus and $52,550,771 in banks. Gross business was $206,867,347.

13—Maxwell earnings gained 135 per cent in year. Net assets were $11,176,783 as against $3,500,000 in 1915. Cash on hand was $3,269,552 as against $2,652,628 in 1915. Car sales increased 88 per cent over 1915.

29—Reo Motor Car Co. and Reo Motor Truck Co. gross sales amounted to $27,884,000 in 1916, including 23,753 cars and 2,551 trucks. Passenger cars increased 33.08 per cent and trucks 33.38 per cent.

20—Saxon Motor Car Corp. profits are $1,316,272 for year ending June 30, or equal to $22 a share on the $6,000,000 stock. Output of company was 25,500 cars, an increase of 15,651 over 1915.

20—Packard surplus is $10,823,717. Gains, $6,206,419. Total assets increased $11,830,505. More than $6,000,000 added to surplus.

21—White Motor Co. for 6 months' period ending June 30 shows net profits of $2,635,784. Has surplus of $1,623,521, equivalent to 11 per cent on $16,000,000 capital stock. Total income is $2,750,923.

Obituary

FEBRUARY

23—Lewis R. Speare, president of the A. A. A. in 1909 and 1910 and president of Massachusetts State A. A. in Newton, Mass.

APRIL

8—Bob Burman, frequently characterized as the world's speed king, was killed at Corona, Cal.

MAY

13—Carl Limberg, racer, was killed at Sheepshead Bay, N. Y.

15—Ludwig Opel, German car manufacturer, killed at Verdun.

26—Georges Boillot, winner of the French grand prix in 1912 and 1913, was killed in an aerial battle with five German aeroplanes.

JUNE

1—James K. Stewart, one of the founders of the Stewart-Warner Speedometer Corp., Chicago.

JULY

15—Paul Smith, vice-president and general sales manager of the Chalmers Motor Co., Detroit.

SEPTEMBER

21—L. S. Bache, Bound Brook, N. J., first vice-president and general manager of the Bound Brook Oil-less Bearing Co.

OCTOBER

12—R. S. Crawford, founder of the Crawford Automobile Co., Hagerstown, Md.

20—Henry Spiitdorf, inventor of the magneto bearing his name, in New York.

30—Hughie Hughes and Frank Galvin, killed at Uniontown race.

NOVEMBER

4—Philip Braender, president of the Braender Rubber & Tire Co., Rutherford, N. J.

Apperson Bros. Co. New $300,000 Factory

As announced in THE AUTOMOBILE recently, Apperson Bros. Automobile Co. is now in its new $300,000 factory, the transfer having been effected without impairing production by keeping machines working up to quitting time and then moving them to their new location during the night. The main building of the new plant is 150 by 610 ft. and contains the machine shop and erecting department. The blacksmith shop is 40 by 128 ft. and is newly equipped throughout. The metal-working department, enameling room and rough stock rooms are in a building 110 by 230; boiler and engine room is 60 by 78, assembly and paint shops 160 by 245, test barn 34 by 118 and chassis test shed 28 by 254. Over 500,000 sq. ft. additional space is available in the new plant and further additions are already planned. The present capacity is 4500 cars a year.

New $300,000 factory group occupied by Apperson Bros. Automobile Co., Kokomo, Ind.

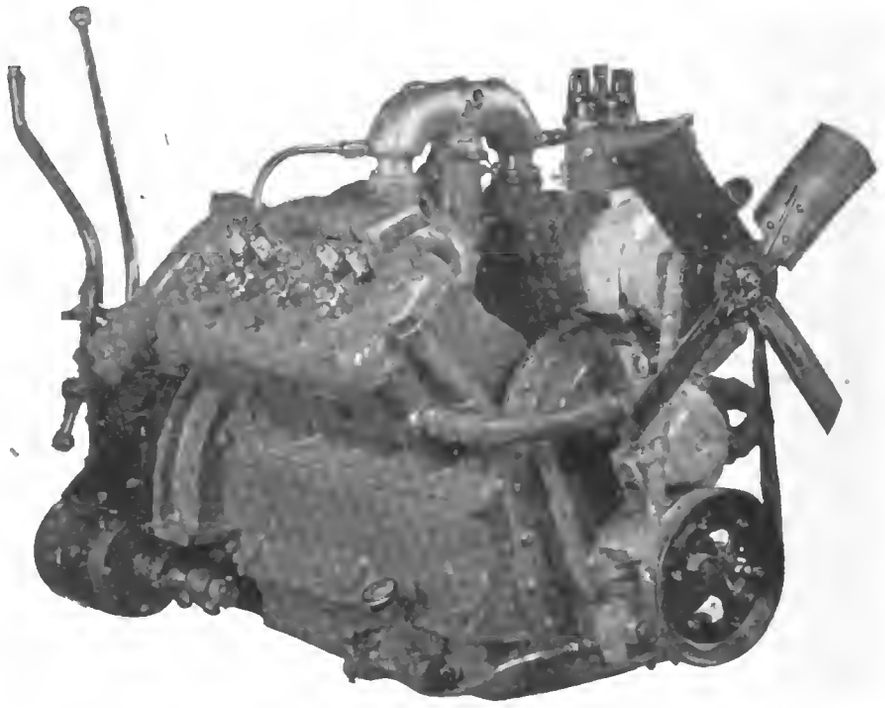
New Eight Succeeds Olds 44

Skeleton of Previous Model Remains but New Product Redesigned and Refined Throughout—Fan and Generator Combined

FUNDAMENTALLY the new Oldsmobile 45 is a continuation of the model 44 eight made last year. It has so many improvements, however, and so many parts have been redesigned that it may well be called an entirely new model. The general dimensions, such as the wheelbase, bore and stroke, etc., have been unchanged, but the details of the car have been altered in a great many respects and a great advance in engineering practice in the many considerations which go to make up performance, has been made.

What has been done may be realized when it is stated that with the same dimensions the power plant shows an increase of 25 per cent in horsepower. The present engine gives 56 hp. at 3200 r.p.m. The previous engine showed 45 hp. at 2800 and both are 2⅞ by 4¾. About the only thing that remains the same on the engine is the cylinder block.

This is a V-shaped unit with a detachable head and vertical-split crankcase. The head has been changed materially so that there is now more water space and the connection to the cylinder block is firmer. Three studs have been added to give a better connection and the head is carried over the cylinder wall to a greater extent, giving more water volume. Another point accomplished by the re-arrangement of the studs is that the strain given in tightening them, is removed from the valve seat so that there is no danger of distortion.



New Oldsmobile eight-cylinder 2⅛ by 4¾-in. engine, which develops 56 hp. at 3200 r.p.m. Note mounting of generator and ignition unit at front of cylinder blocks, generator and fan now being assembled together on the same shaft

While the Lynite pistons have been continued, the design is very different from a year ago, particularly in regard to the elaborate precautions taken to avoid oil pumping. There are three rings above the wristpin and one below. Six holes are drilled in the lower edge of the bottom ring groove and six in the upper edge. There are also two holes drilled diametrically opposite one another at right angles to the wristpin. The lower edges of the three upper ring grooves are chamfered as are top and bottom of the lower groove.

The present connecting-rod assembly weighs 17½ oz. This is a reduction over a year ago obtained by machining the rods all over. These are forked rods with square 2⅛ by 2⅛-in. bearings. The connection to the wristpin at the upper end is unchanged. The pin is locked in the piston boss with a set screw having a cotter pin in the center of the hollow wrist pin. This takes all stress off the cotter pin. The pin is not made of tube but is drilled from the solid piece.

A new crankshaft with a very complete counterbalancing system is now employed. Three counterweights are mounted on the shaft to take care of running balance. The shaft is also in static balance. The counterweights are electrically welded to the shaft after the latter is forged, the weld being a see-saw joint giving the greatest possible area of metal to metal contact at the connection. The shaft is carried on two main bearings, and is noteworthy for its shortness. The overall length is 25¾ in. The front bearing is 1⅞ by 2⅞ and the rear 2⅛ by 3¼.

The entire front end of the engine has been changed. The valve drive is much the same except that a Fabroil gear is now used for silence, but the generator which was formerly driven by chain is now driven by belt, and is mounted on the same shaft as the fan. The generator and fan run on two bearings, a Hyatt roller and a New Departure double row ball, taking thrust and radial load. The two units are now assembled together while the fan was formerly a floating design driven from a spline shaft from the generator sprocket. The belt is a V type, ¾ by ⅜-in. section, riveted on lugs. The ratio of the fan to the shaft is 1½ to 1. This ratio gives pulleys of large diameter and hence imparts considerably longer life to the belt.

A new adjustment for tension on the fan and generator belt has been installed. This consists of a hollow plunger which is integral with the generator bracket and working in the front gear cover. There is a spring behind the plunger which is held by a pinch bolt. When the pinch bolt is released the spring causes the plunger to take up the slack after which the pinch bolt is again tightened.

To take care of the timing gears more efficiently a change has been made in the oiling system. This is a pressure system and a new lead has been added to the main line by means of which oil under pressure is fed directly to the point of mesh of the timing gears. This forces a 3/16 in. stream directly to the desired point on the gear, after which it drains back to the crankcase reservoir.

Another change in the oiling system is in the pump. This is now mounted outside of the front gear housing and can be taken off without interfering with any other part of the engine or even dropping the pan. The pump was formerly located in the front chain housing. It is now possible to take

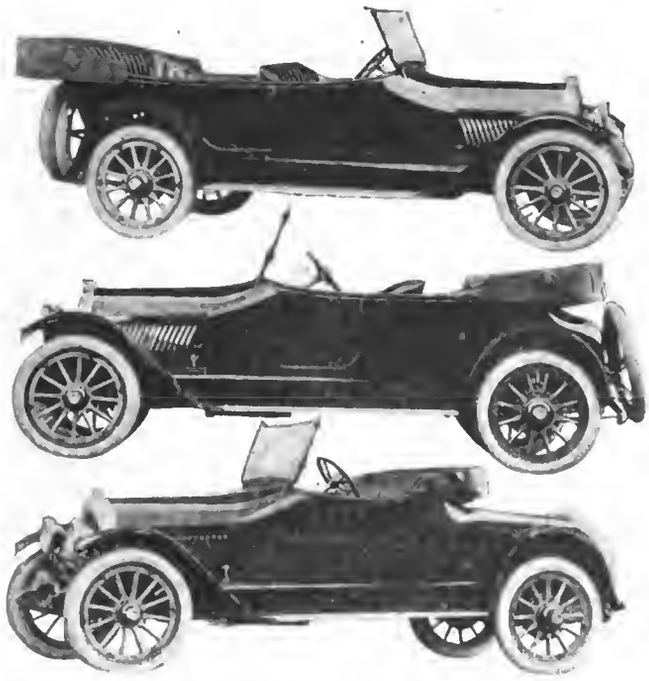
At the left is the new crankshaft, which is very carefully counterweighted for both running and static balance



Upper—Oldsmobile eight-cylinder seven-passenger touring car
Middle—New four-passenger club roadster on same chassis
Lower—Two-passenger roadster, with convertible rear compartment with folding top, providing a seat for two additional passengers

off the pump in 5 min. Another point of simplification is the placing of the oil regulator in the crankcase. This is particularly good from a manufacturing standpoint as it cuts out three unions in the piping.

With the exception of the use of flexible pipe instead of rigid from the vacuum tank to the engine, the gasoline system is the same as a year ago. The object of the flexible hose is to eliminate the effects of non-synchronized vibration. As the engine is mounted flexibly in the frame it is natural that any connections between the chassis parts and the engine should be preferably flexible.

In the cooling system the greatest improvement is in the cylinder head. The radiator has also been changed and is now an oval shape of very distinctive appearance. The capacity of the present cooling system is about 5 gal. as compared with 4½ gal. on the previous model. The pump and pump drive have been improved. The drive is an ingenious sheer-clip scheme in which the drive is taken from the nut holding the camshaft gear in place. The clip is slipped into the slots of two shafts which come end to end and being the weakest part of the drive; in case the pump should freeze the clip would shear thus preventing harm to any other part of the system.

The pump housing is now attached by an oval flange to the front gear cover, giving a rigid connection. Formerly the pump was supported directly on the camshaft and was hence a floating type. An all rubber hose connection is now used instead of a metal elbow.

Some miscellaneous points which should be mentioned in connection with the new cylinder head are the location of the spark plugs which are now over the intake, and the fact that the center line of the valves is inclined at an angle of 8 deg., 55 min. to the center lines of the cylinders. Better combustion is said to result from the first and better gas flow from the second.

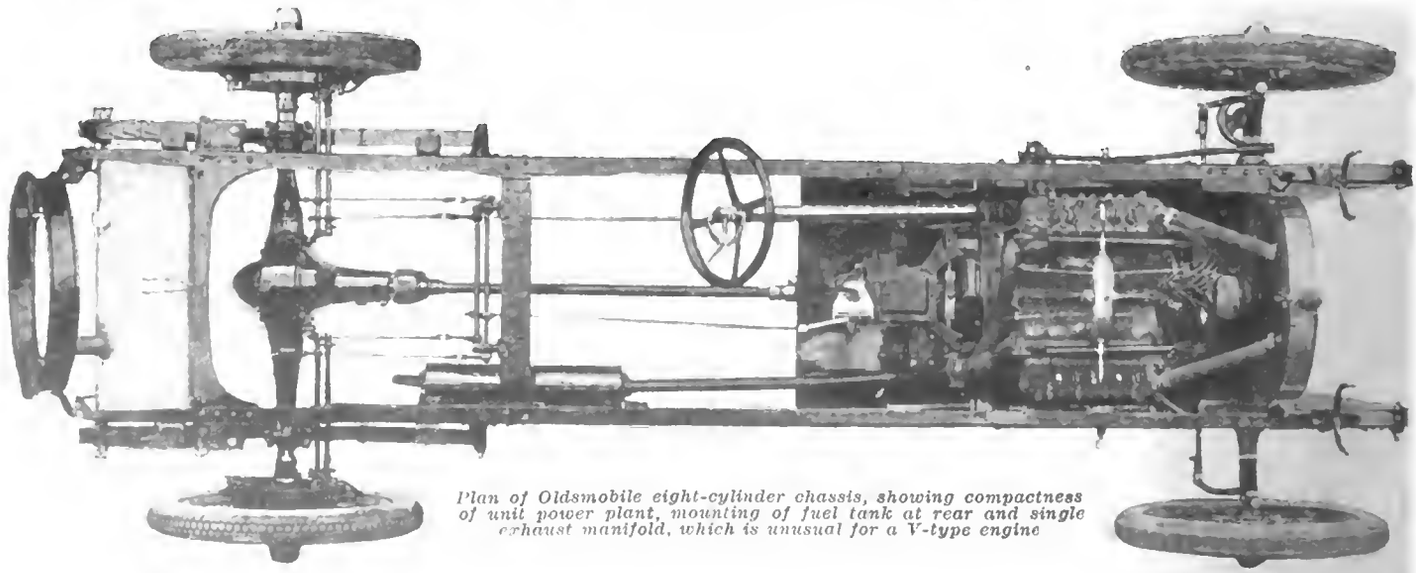
No changes are to be noted in the clutch. This is a cone with four engaging springs and no adjustments. Beneath the facing there are easy engaging springs. A clutch brake is formed by a pad on the front end of the transmission and the throw-out is a ball design. The clutch diameter is 12½ in. maximum.

The gearset also remains unchanged. This is a three-speed box with a four-spline main shaft mounted on a Hyatt roller at the front end and a New Departure double row at the rear. The shafts and gears are chrome nickel steel with ¾-in. face on the sliding gear and 1 3/16-in. face on the constant mesh gear. On the main shaft the bearings are close, giving only 7 ⅛ in. of unsupported shaft. A long Hyatt roller is used for the spigot bearing and the lay shaft is carried on two bronze bushings.

Two Spicer universals are just being added to the drive. The shaft is hollow and is slightly larger in section than last year in order to take care of the greater torque of the improved engine, being increased from 1½ to 1¾ in.

An increase in gear ratio has been made this year in the touring rear axle. This is now 4 11/12 to 1; it was 4 5/12. The pitch is 4½. A truss has been added to the axle to brace it against strain. This is adjusted by a heavy turn buckle beneath the differential housing. The rear springs are the same 48-in. three-quarter elliptics in the rear, but the front springs have been flattened. A detail is that the leaves are now diamond pointed instead of straight cut as formerly.

In the frame construction, the same layout is used with the exception of the front end where the trunnion support of the engine has been given up and a special cross member used instead. The three point effect is retained, however, with the new layout. Another detail is in mounting the front springs; the castor effect is secured by mounting them ahead of center. These are 36-in. springs and 17 in. is ahead of the clip center



Plan of Oldsmobile eight-cylinder chassis, showing compactness of unit power plant, mounting of fuel tank at rear and single exhaust manifold, which is unusual for a V-type engine

with 19 in. behind. Both drive and torque are taken through the rear springs.

There are four bodies in the new series, a seven-passenger touring, five-passenger touring, four-passenger club roadster and a two-passenger roadster, the rear compartment of which can be converted into an extra seat for two passengers. Taken with the new German silver trimmed radiator, new flared mud apron and grooved lamps, matching the radiator, an attractive appearance is presented. The prices of these models are $1,295 for the seven-passenger touring and $1,295 for all the others.

Many Colors Available

The upholstery is long grain, bright finish French leather, box plaited and stuffed with close-nested, small diameter springs, incased in linen sacks. The cowlboard is Circassian walnut with silver finished instruments mounted flush. The steering column is nickeled, with a walnut wheel.

A wide variety of color is offered, the seven and five passenger cars being in royal green, the club car is royal blue and the convertible roadster in carmine, with the above colors optional for any model at a slight additional cost.

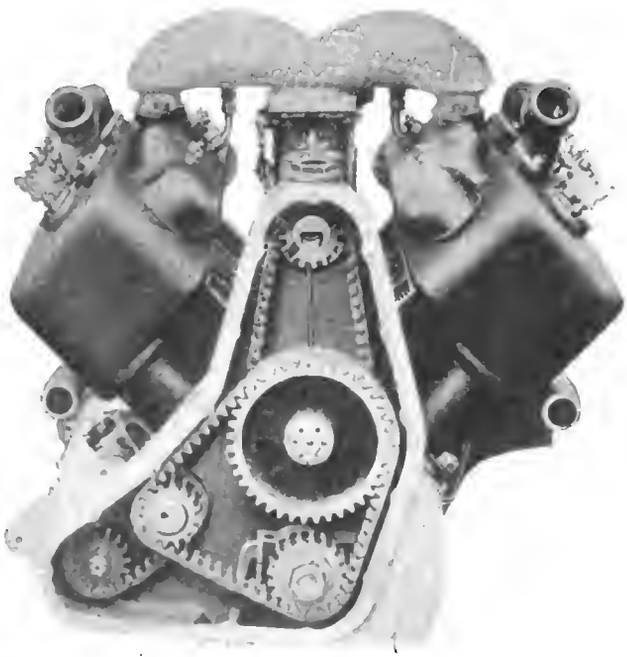
Driver's compartment of Oldsmobile eight, showing large seat, conveniently arranged instrument board and control members

Majestic Makes Two Eights

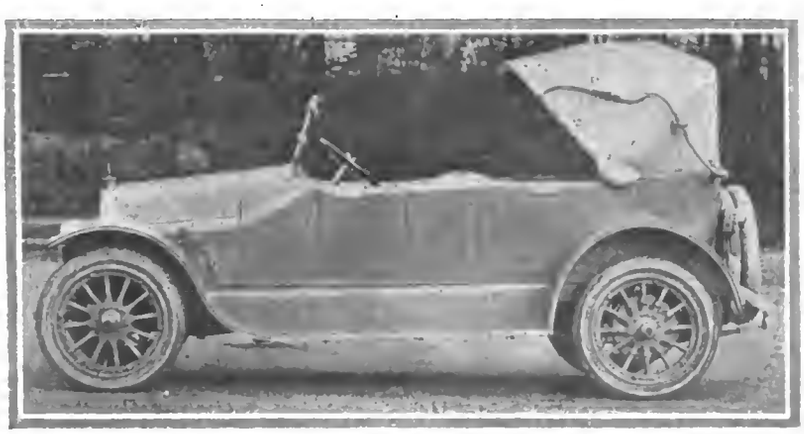
Extremely Luxurious Bodies Leading Characteristics of New Production

THE Majestic cars, made by the Majestic Motor Co., New York, are among the list of new cars announced in December. There are two chassis, one with 125-in. wheelbase and a 3 by 5-in. eight-cylinder engine selling for $1,550, and the other, which costs $3,000, has ten inches more wheelbase and an eight-cylinder engine 3¼ by 5 in. The two chassis depart but little from good conventional practice and appear to be laid out nicely, while they are of a sturdy character.

The appearance of the cars is unusually distinctive, largely because of the rounded radiator and specially designed headlights. A tilted windshield and double cowl are employed. The tonneau embodies several features which should appeal to the discriminating owner, particularly if he does much touring. The front of the rear seat is a mahogany paneled compartment, the interior of which is large enough to hold several lunch boxes, dusters and other articles. The door lifts up with lock hinges, forming a table so that the lunch may be comfortably eaten right in the car. At the right is a compartment fitted with a vacuum bottle and a cigar lighter. At the left there is a compartment containing a vacuum ice and solid food container. The tonneau equipment also includes a lady's toilet set and the usual robe rail and cushion foot rest. The carpet is lined on the bottom with a waterproof oilcloth which may be turned over in wet weather, thus saving the carpet.



The engines used on the Majestic chassis are both eights, of L-head type, and have this silent chain layout for the front ends. The idler sprocket shown on the left furnishes the adjustment for the triangular drive from the crankshaft, the sprockets for the generator and for the fan being adjustable separately



Very luxurious bodies with a lavish equipment of accessories and fittings are supplied. The car shown on the left sells for $1,550 with a one man top instead of the Victoria type illustrated

Flexibility in Hydraulic Transmission

Radcliffe Hydraulic Transmission Acts as Clutch, Eliminates Need for Intermediate Gear and Gives Electric Flexibility to Drive—Can Stop and Start on High Gear by Throttle Movement Only

THE Radcliffe hydraulic transmission may be described briefly as a hydraulic clutch which automatically gives a similar effect to that obtainable from an electric transmission. With it a car can be started from rest on high gear without any shock or difficulty, merely speeding up the motor causes the car to move forward, and the car can be stopped on the brake without stalling the engine. Its flexibility can best be demonstrated by taking the car on a grade where, without manipulating anything except the throttle pedal, it is possible to go forward, to allow the car to run backward, to arrest it and start it forward again without touching either brake or gear lever. It is anticipated that this transmission will eliminate the necessity for an intermediate gear ratio, although it is not suggested that it removes the necessity for an emergency low speed.

Replaces Clutch

The device replaces the ordinary clutch. It consists of an aluminum or pressed steel casing provided with turbine blades in the manner shown in the illustration. The driven member has similar corresponding turbine construction and the whole case is filled with oil. Assuming the driven member to be held stationary, as it would be when in connection with the road wheels of a stationary car, if the engine is running slowly the oil will circulate around the turbine blades but will offer very little resistance. As soon as the engine speeds up the rotating part of the turbine forces the oil with considerable pressure into the stationary part, which is thereby caused to follow it, and as the car gains speed the difference in rate of revolution between the driving and driven member will gradually decrease until there is very little slip indeed.

The secret of success of the device really lies in the detail design of the turbine members. On meeting a hill the slip increases a little, thus allowing the engine to maintain its speed, and although, of course, a certain amount of power is lost in heating the oil the flexibility given in this way will provide the equivalent of an intermediate gear ratio. It is practically only when actually starting on a stiff grade that it is necessary to engage a low gear.

The development of the transmission has taken a good many years, experiments being directed mainly toward ascertaining the proper shape and proportion of the turbine blades. Consideration of the photographs and of the sectional drawing will show that the impeller discharges directly into the runner and that the oil then passes back again into the impeller.

It will be noticed, of course, that there is a stuffing box at the center where the driven shaft comes out through the driving casing. It might be thought that this would require to be extremely tight, but such is not the case, because the transmission is not filled completely with oil. A little air is left inside and as soon as the engine starts to run the centrifugal force carries the oil outward, thus bringing the air to the center and taking away all the oil from around the gland.

The final experimental model has been in use for over 6 months on a six-cylinder Studebaker and is being handled by the A. Elliott Raney Co., 244 West Fifty-ninth Street, New York. In the several thousands of miles of driving no hill work has ever caused the oil to heat unduly and the gasoline consumption over a long period is closely similar to the previous record of the same car with the gear transmission. The transmission is very practical for manufacturing.

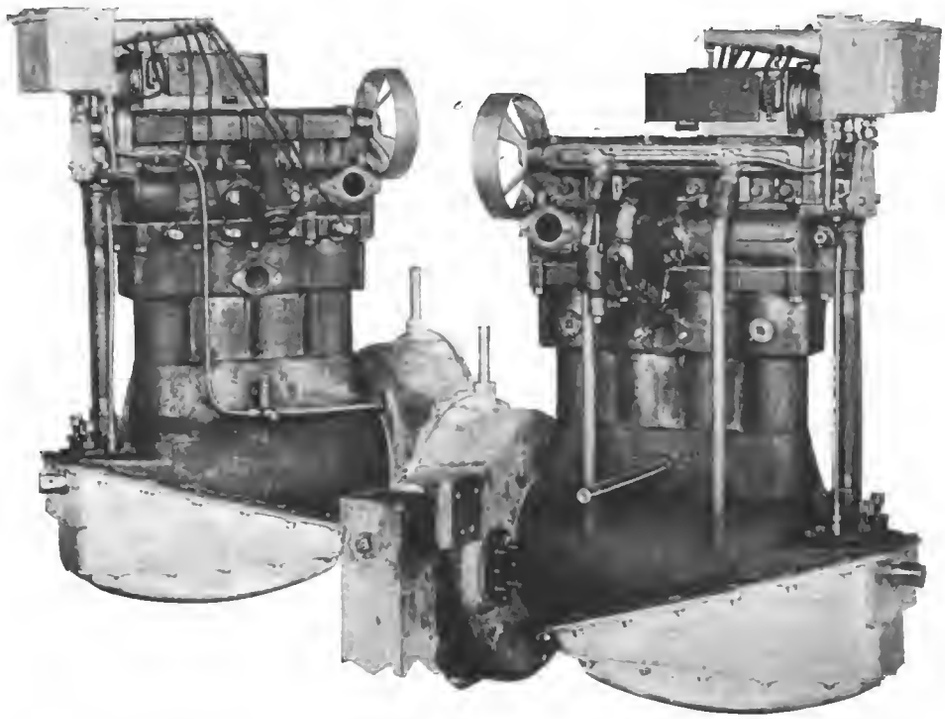
Nelson Is Unique Design

37 Miles Per Gallon Claimed for $2,200 Car—Overhead Camshaft and Original Transmission—Weight Kept Low

FOR 4 years, E. A. Nelson, the engineer who designed the well-known Hupmobile 20 runabout made during the years of 1910, 1911 and 1912 and the model 32 which succeeded it, has been working on a car of its own. This is now ready and the first finished jobs have been shipped to Eastern points, where distributors have already been engaged.

The Nelson cars are not only distinctive mechanically but otherwise also. The cars are not made by a company but by Nelson himself, financed with his own money and manufactured in his own plant in Detroit, which has a capacity of ten cars a day. There is no stock for sale and no intention of organizing a stock company. It represents the effort of an engineer desiring to place on the market a light-weight vehicle of economy, made from high grade materials, with price occupying a rather subdued position.



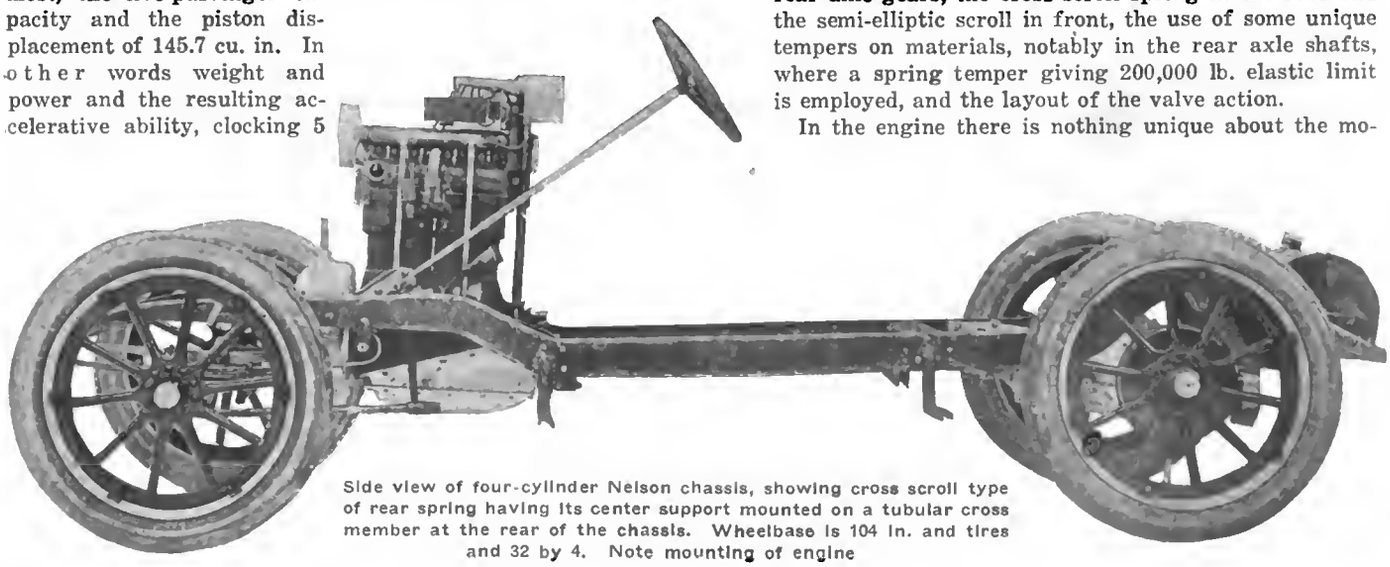
Nelson four-cylinder block power plant, which has an overhead camshaft. The unit gearbox incorporates clutch, gearset and rear axle gears. Bore is 3⅛ and stroke 4¾ in.

The result is a vehicle weighing 2200 lb. with the tanks empty, claimed to be able to travel 37 miles to the gallon and to average better than 25, selling for $2,200 with a sedan body. From one end to the other the design is distinctive, although there is nothing radical. A great number of patented features are used, however, and the finished product shows the result of a considerable amount of study of detail which has resulted in many ingenious departures.

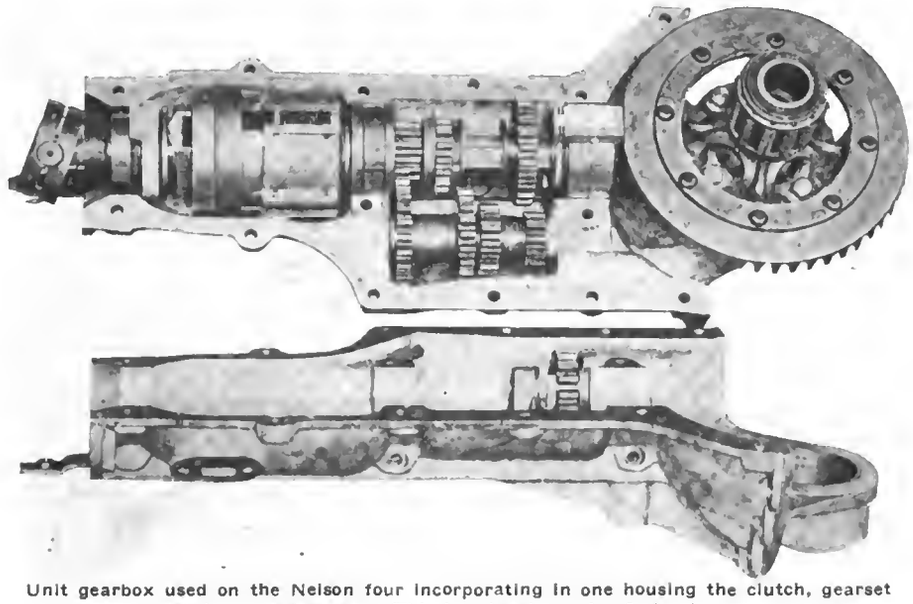
In working out this design two ideas were kept uppermost, the five-passenger capacity and the piston displacement of 145.7 cu. in. In other words weight and power and the resulting accelerative ability, clocking 5 to 35 m.p.h. in 13.5 sec., checks up the results. Throughout, the materials have been designed for this particular capacity with a particular eye toward economy, which means lightness. The finished vehicle carries only 3 gal. of water and 5 qt. of oil, 2 of which are in a reserve tank.

Some of the high spots on Nelson's car are the overhead camshaft used on the block four engine, the unit transmission incorporating in one housing the clutch, gearset and rear axle gears, the cross scroll spring in the rear and the semi-elliptic scroll in front, the use of some unique tempers on materials, notably in the rear axle shafts, where a spring temper giving 200,000 lb. elastic limit is employed, and the layout of the valve action.

In the engine there is nothing unique about the mo-



Side view of four-cylinder Nelson chassis, showing cross scroll type of rear spring having its center support mounted on a tubular cross member at the rear of the chassis. Wheelbase is 104 in. and tires and 32 by 4. Note mounting of engine



Unit gearbox used on the Nelson four incorporating in one housing the clutch, gearset and rear axle gears. This housing is made of aluminum

tor block itself. This is an iron casting with the upper part of the crankcase integral. The heads are detachable, carrying the entire valve assembly and the manifolds, and above the head there is an additional cap carrying the camshaft assembly, also acting as an oil housing for the latter which runs in a continual bath.

In the piston and rod assembly there is nothing exceptional but the rod section. This is a shallow I designed for extreme stiffness in the plane of rotation without a mass of material on the flanges for perpendicular strength. The piston is iron and carries four rings. These are in two slots, each slot carrying two rings of the ordinary eccentric type with the rings dowel pinned to the piston to hold the slots at opposite points on the circumference to avoid leakage. The rings are thus locked in pairs.

The piston pin is hollow, 1 in. in diameter, locked in the upper end of the rod by a pinch clamp and taking its bearing in the piston bosses directly without bushings. The bearing space is 1 in. in diameter and 1 in. on each side, giving a total dimension of 1 in. diameter by 2 in. length. The I-beam rod has a flange width of ⅜ in. The depth of the I is 1⅛ in. at the center with a taper toward the bottom. The stock used is 3/32 in. through the center of the web, the material being chrome vanadium steel. The rod length is 10½ in., and the weight of the entire assembly of piston and rod is 3 lb. 2 oz. Without the piston the rod assembly weighs 1 lb. 12 oz. The bearing at the lower end is 2 in. in diameter and 1½ in. long, provided with two 3½ nickel steel cap bolts.

A counterweighted crankshaft is used, the particular feature of which is the thickness of the cheeks. The thickness of these on the sides adjacent to the two center bearings is 2 7/16 in. The counterweights are made up to balance the throws, plus one-half the rod weights. The material used in the shaft is 0.40 carbon steel, with the counter-weights electrically butt-welded into place.

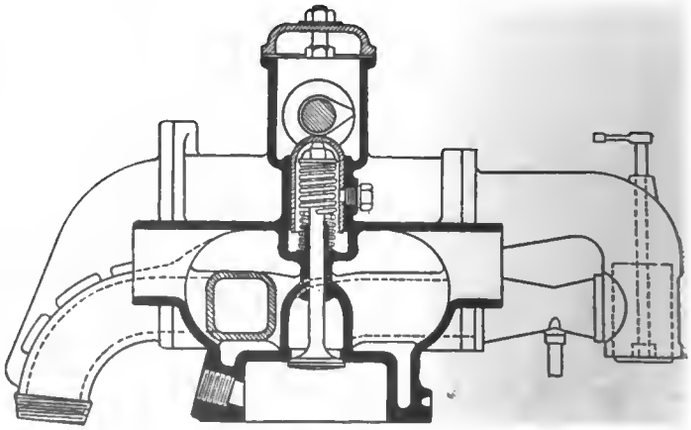
From the crankshaft the valve drive is carried to the overhead camshaft by bevel gear and vertical shaft. The bevel gear is mounted directly on the rear end of the crankshaft and housed directly in the rear main bearing. This is a chrome-silico-manganese, commonly known as C. S. M. steel gear. The vertical shaft tapers from ⅝ in. at the gear to 9/16 at the top and has a 1 to 1 ratio with the crankshaft. The helf-time ratio is secured at the top, where an adjustable spiral bevel transmits the drive to the camshaft. Back of the camshaft spiral bevel gear is a spur gear which forms the magneto drive, the instrument being mounted on the top of the engine and being a special Bosch arranged so that the magnets lie flatly on the top of the cylinder head.

The camshaft lies directly in the head piece of the engine. At the rear end is the spiral gear through which it is driven and at the forward end is the fan pulley which it drives. It is a short, stiff shaft, carried on five bearings cut directly in the cast iron. The camshaft can be slipped into place from either end and carries the cams integral. These are the true, constant-acceleration type, designed to run with 0.005 clearance and giving conventional timing with no provision for valve adjustment. The heads of the hollow tappets and the valve stems which fit into the tappet are ground to finished accuracy after which no adjustment is required. The intake opens 15 deg. after top center and closes 35 deg. after bottom center. The exhaust opens 45 deg. before bottom center and closes 10 deg. after top center.

Across the diameter the camshaft measures 1⅝ in. at the bearings. The three center bearings are ¾ in. long and the end bearings ⅞ in. This is a low carbon steel shaft hardened at the rubbing point. A piston type of tappet is used fitting around the valve stem. The tappets are pressed steel hardened and ground, 1⅛ in. diameter, with the follower ground to a true radius. The valve drive operates with a 28-lb. spring.

Full pressure oiling is used running up to 30 lb. per sq. in., with an exterior adjustable release. No splash is used to any of the bearings, the oil being circulated through the hollow crankshaft and with an independent lead directly to the camshaft housing, where it keeps the shaft bearing continually bathed in oil. This circulating system is operated by a pump formed by the drive gears at the lower end of the vertical valve shaft and has a capacity of 3 qt. In addition to this, there is a small tank mounted on the top of the engine having a reserve capacity of 2 qt. which can be allowed to flow into the main reservoir whenever the oil indicator shows no pressure.

A special adaptation of the U.S.L. starting and lighting system is used, in which the unit is mounted, as customary, as a flywheel at front end of motor. The fields are stationary, with the armature rotating and forming the flywheel. The hub for the rotating member is a standard taper fitting on the end of the crankshaft, while the stationary member is carried on a projection of the crankcase. This



Layout of the overhead valve action on the Nelson four

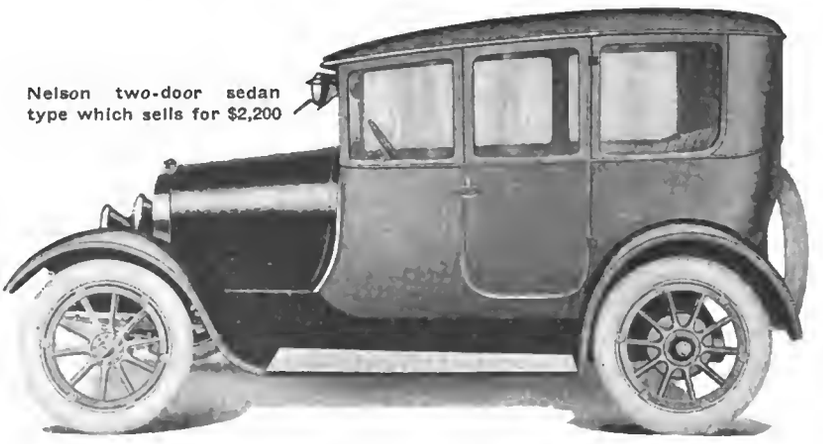
is a 12-volt system with inherent regulation. Ignition is by the specially-built Bosch instrument and the storage battery is a U.S.L.

For carburetion a Zenith instrument is used with a vertical flange directly against the cylinder head which contains the integral manifold. The carbureter is featured by an inclined header designed to eliminate the pocket found with a horizontal header at the venturi and patent has been applied for on this feature. The economy of the car focuses around the construction of the intake manifold, which is so formed that the longest draw from the carbureter to the farthest intake port is 4 in. The water around the cylinder head is kept at about boiling temperature, summer and winter, thus giving the heat required with the present grade of fuel and allowing operation with anything that is called gasoline. Another feature about the throttle linkage is that it is laid out to give a uniform opening at low throttle position.

Cooling is by thermo-syphon with a cellular radiator which has a feature of note in that the overflow pipe is carried to the bottom of the radiator, allowing the steam formed in case of a gathering of slushy ice in the bottom to thaw out the cooling system.

The clutch receives its drive from a shaft and single universal, being mounted in unit with the gearset and rear axle. The diameter of the clutch is 3¾ in. and it is comprised of thirty disks of saw steel running in oil. The axle is floating with ⅞ sq. in. chrome vanadium steel shafts, heat treated with a spring temper giving 200,000 lb. elastic limit. The housing for the clutch, gearset and transmission part is aluminum, and the gear reduction at the rear axle is 4.25 to 1. The propeller shaft is 11/16 chrome vanadium steel.

A cross scroll type of rear spring is used with the center support mounted on a tubular cross member at the rear of the chassis, giving a slight compensating or rocking action. The scrolls at the ends of the spring serve as centering devices and supplant the shackles. On the front springs the scrolls are also used and they serve to take up the shock between the frame and the spring and also give a flexible drive to the front axle.



Nelson two-door sedan type which sells for $2,200

There are six cross members in the frame, those at the front and rear being tubular. The steering gear has a divided drop arm which equalizes the bearing stresses on this point. There is also a forked wheel spindle which distributes bearing stresses and takes care of the castor effect. Additional castor is given by mounting the springs ahead of center, the distance being 16 in. front and 18 in. rear. The brake linkage also has a little kink of interest in the use of sectors for expanding the bands. The brakes are both expanding, being side by side on the same drum. The diameter of the latter is 11½ in. and the face width 1¼ in.

The wheelbase is 104 in. and the tire size 32 by 4. It is stated that upward of 12,000 miles has been shown on the test cars to a set of tires. The speed range is from 5 to 50 m.p.h.

It will be noted that in the body lines the cowl is entirely eliminated, the hood being in direct contact with the body proper. It is a two-door sedan type with divided front seats, upholstered in gray bedford cord, as is also the top lining. The cushions are tufted with real curled hair over heavy springs. All the windows can be lowered into the body sash and a double windshield is employed. Standard equipment includes a Moto-Meter, Stewart speedometer, Waltham clock and ammeter, gasoline and oil gages, dash light, tools, tire pump, etc.

Chalmers Six Hauls 15 Tons ¼ Mile

Chalmers Six-30 chassis hauling a 15-ton steam-hammer ¼ mile to factory

INSTALLATION of heavy machinery at the big automobile plants presents problems that only resourceful factory managers can solve.

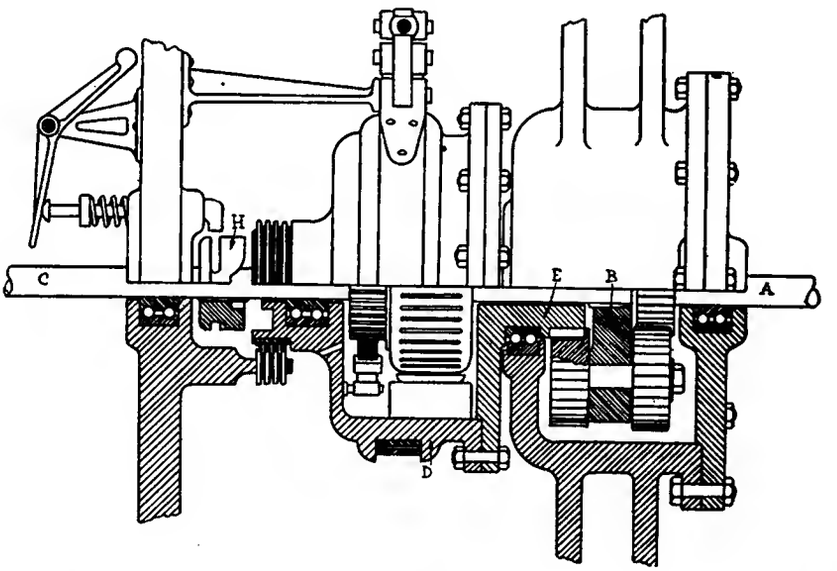
During the fall a big steam hammer arrived at the plant of the Chalmers Motor Co., Detroit, for installation in the drop-forge building. The steam-hammer weighed in excess of 15 tons, and after being unloaded from a railroad flat car, had to be moved a distance of ¼ mile.

A Chalmers Six-30 chassis was hurried over from the final test department, hooked up to the big hammer by heavy ropes and the power was turned on. So heavy was the ponderous piece of machinery that steel rollers placed under it were crushed like egg shells and the ropes lasted for only short periods.

But the 2000-lb. chassis moved its 30,000-lb. load along steadily and the hammer was in position within an hour after arriving at the factory.

A Cuban Electric Transmission

Electric Unit Combined with Planetary Gear Permits Reduction of Size and Weight — Direct Drive Given by Engaging Dog Clutch



TO the possibilities of electric and electro-mechanical transmission systems there seems to be no end. One of the most interesting is illustrated on this page. It has two special advantages; first, it gives a direct drive on high gear, both the electrical and mechanical portions then being inoperative. Second, the horsepower of the electrical portion needs only to be one-half that of the gasoline engine. The action can be very readily followed from the sectional illustration in which *A* is the engine shaft. It will be seen that this drives the sun wheel of a planetary gear. The armature of the electrical machine and the pinion carrier *B* are both fixed to the shaft *C* which is the driven shaft to which the universal joint is attached for the propeller shaft. The field magnet case *D* turns freely on the shaft *C*, but has integral with it a second sun wheel *E*, being thereby connected to the engine through the medium of the planet pinions which are both on their shaft.

Now assume *A* to be rotating and *B* stationary, then the pinions will revolve, and *D*, by means of the sun wheel *E*, will be driven in the same direction as that in which the engine is turning at a speed depending upon the numbers of teeth in the sun wheel on *A* and the sun wheel *E*. Having the field magnets revolving around the armature, as soon as a current is allowed to flow there will be resistance, so that the magnets will tend to drag the armature around with them. This is the equivalent of applying a magnetic clutch tending to start the car by means of the shaft *C*. But there is also the reaction to be considered. The field magnets tend to rotate the armature and the armature tends to stop the rotation of the field magnets. This means that equal efforts are being made, one to turn the shaft *C* and the other to stop the turning of *D*, and so to stop the turning of *E*. The effect of holding *E* is to produce another reaction which drives the pinion carrier *B* in a forward direction. But *B* is keyed to the shaft *C*; therefore, we are trying to turn this shaft both by means of the armature and by means of the pinion carrier, and the turning effort is divided equally between the armature and the planetary gearing.

As the car speeds up we shall reach a position where the shaft *C* is revolving a little slower than shaft *A*, the difference in speed being only just sufficient to maintain enough current to supply the necessary magnetic grip. When this happens the throttle is allowed to close for an instant and the dog clutch *H* is moved by any convenient means, this locking *D* to the shaft *C*. Then no current is being generated, since the armature and the magnets are revolving at the same speed and there is no relative motion between the different parts of the planetary gear.

To obtain the reverse there is a brake band surrounding *D* whereby it can be stopped from rotating and *E* being stationary will cause the pinion carrier *B* and shaft *C* to travel in a reverse direction.

This is merely the simplest expression of the invention, which is susceptible to many variations of detail. The inventor is Carlos M. Seidel, an electrical engineer of Havana, Cuba, at present residing in New York. He is anxious to make arrangements for the manufacture of an experimental outfit and may be addressed in care of THE AUTOMOBILE.

New Process Rubber—Plates Metal

Soft Rubber Attached to Steel So That It Cannot Be Torn Off—Employed for Solid Tire Making and New Flexible Coupling

THE attachment of rubber to metal is a subject which probably is not much considered by engineers, yet for many purposes a process which enables soft rubber to be fixed to steel is very useful. The first instance that occurs is, of course, an electrician's pliers where the rubber is necessary for insulation. Another place where the two dissimilar substances require to adhere is in the band type of solid tire. Yet another example is the roller skate wheel, for skates intended to be used in offices.

The old way of attaching rubber to metal was to make the metal surface very rough so that the rubber, when vulcanized in place, would be held mechanically by the rough metal. A new process has recently been developed by the Rubber Insulated Metals Corp., Plainfield, N. J., whereby soft rubber can be made to stick to metal so strongly that the rubber can be torn off afterward and will break above the junction line rather than at it.

To obtain this close adhesion, it is not necessary that the metal should be very rough. The first stage consists of plating the surface of the steel with a copper alloy having very much the appearance of brass. Then, in mixing the rubber previous to vulcanizing, certain substances are added

which have a chemical action on the copper alloy when subjected to the vulcanizing heat. Vulcanizing proceeds exactly as though the metal were not there. In the case of a pair of pliers, for instance, after they had been plated the rubber compound would be put on the mold and vulcanizing then takes place at the same temperature in about the same time required formerly. Repeated experiments show that after this treatment the rubber can only be torn off with difficulty, and when as much as possible has been removed in this way it will be necessary to scrape or cut in order to get down to the metal surface, so strong is the tie between the metal and rubber that is established during vulcanizing process.

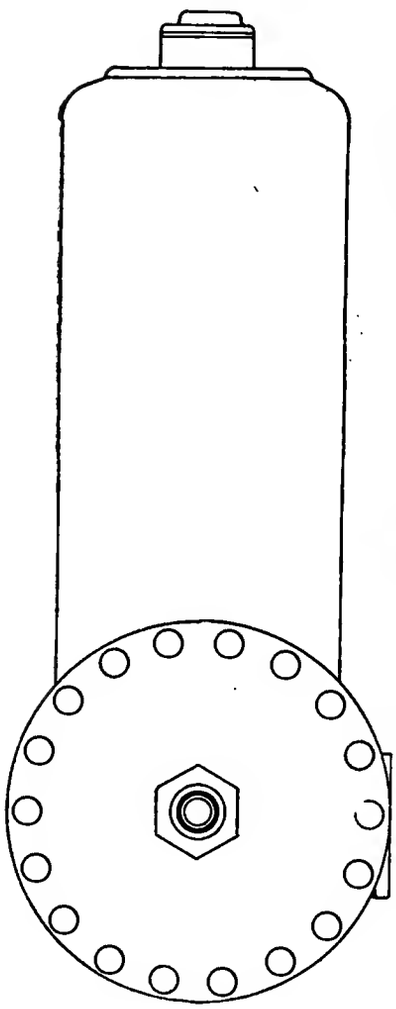
There seems to be hardly any end to the possibilities of this process. One of its most useful fields of application is claimed to be in solid tire manufacture, the Rubber Insulated Metals Co. stating that a tire with a given amount of rubber of a given quality can be produced more cheaply by their method than by any other. In other words, they think the process will effect a substantial economy in solid tire cost.

Another use for the process is for making flexible couplings, and it is anticipated that there will be a big demand for these in the automobile industry. The coupling is shown in the accompanying illustration and there is no metallic connection whatever between the two steel parts. The wave formation of the steel is carried right across and a half inch or more of rubber, according to the size of the joint, separates the two metal parts. These joints have been made in many sizes and tested in many ways and should have many automobile uses. In this coupling the rubber is normally in compression, as can be observed by looking carefully at the illustration. It is not suggested that the joint is flexible enough for use where much disalignment exists, but it will care for as much as a leather disk magneto coupling.

Rimco rubber-metal flexible coupling

Carter Tank Pumps Fuel

Diaphragm Oscillated by Cylinder Pressure—Keeps Level Constant—Action Unaffected by Throttle Position

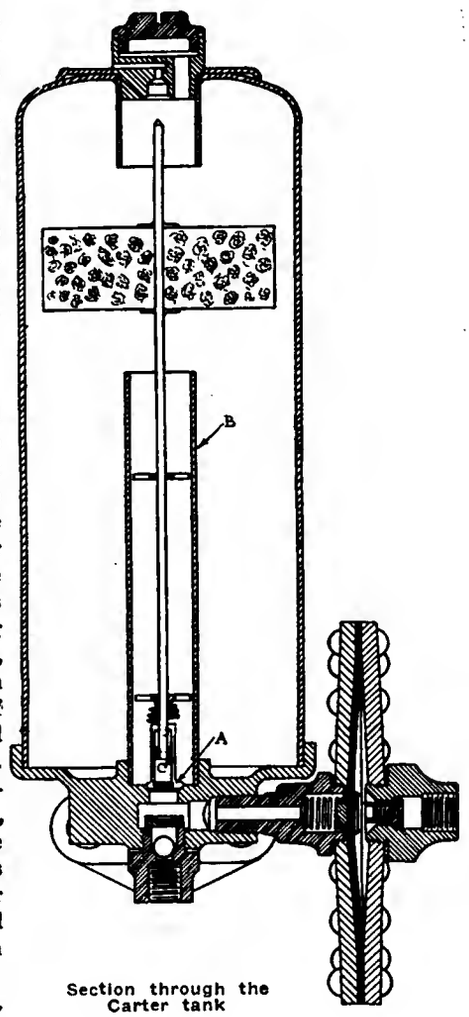


THE Carter system of fuel feed used on the American six, and applicable to any automobile, is a positive pumping system operating without regard to the depression in the intake manifold and also making no use of exhaust pressure. Its essential feature is a diaphragm something like the vibrating diaphragm of an electric horn. This diaphragm is contained in a case and on one side of it there is a spring which normally keeps it pushed back against the opposite side of the case. Here there is a small hole in which a little plunger rests, and behind this plunger is a connection for a copper pipe, of which the other end is taken to one of the cylinders of the engine, usually being fitted to a union in a valve cap or some similar convenient place.

Diaphragm Protected from Explosion

On the compression stroke the air in the pipe is compressed in proportion with that in the cylinder. This moves a little plunger and presses the diaphragm across its case against the spring. When it is pressed as far as it will go the little plunger comes against a seat in the nipple so that when the explosion follows the compression it merely holds the plunger more tightly on its seat and does not transfer any more pressure to the diaphragm. As soon as the pressure drops in the cylinder on the exhaust or suction stroke the spring drives the diaphragm back again to its original position. Thus, during each cycle in the cylinder to which the diaphragm is attached, it makes one complete oscillation. The side of the diaphragm case furthest from the engine is connected by a non-return valve to a long pipe and the gasoline tank. It is also connected with the small tank by which the carbureter is fed. As the spring pushes the diaphragm back, when the cylinder pressure falls it sucks in fuel from the main tank, then on the next compression stroke this fuel is driven upwards into the supplementary tank passing another non-return valve as it goes. It is by means of this second non-return valve that the pumping is caused to cease when the supplementary tank is full.

Referring to the illustration, the valve being shown at *A*,



Section through the Carter tank

it will be seen that it is a mushroom type and on the compression stroke of the diaphragm the fuel is forced upwards until it entirely fills the vertical tube *B* and flows out over the top into the tank. When the level in the tank lifts the float the stem of the latter raises the little plunger *C*, which is inside the mushroom valve. Thus, at the top of its travel the float lifts the mushroom valve off its seat. As soon as this happens the diaphragm, instead of sucking fuel from the main tank, merely draws it from the supplementary one and pumps it back again.

To start the tank, originally when it was first fitted the priming cap at the top of the tank is unscrewed and the gasoline poured in. Once the lower part of the tank is filled it will require no further attention.

The Carter tank is made by the Carter Carbureter Co., St. Louis, Mo.

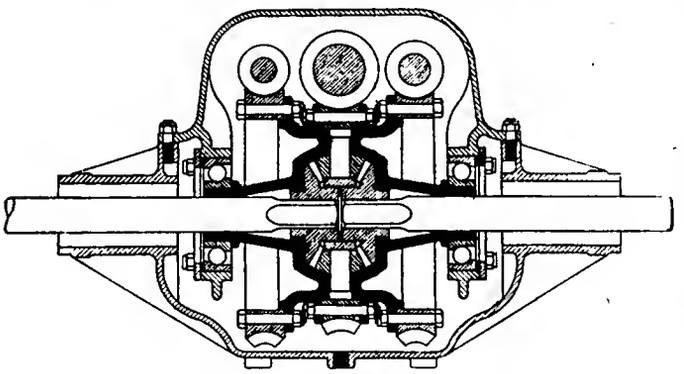
A special claim made for the Carter system is that the fuel level remains very constant. Less than ⅛ in. of movement on the float will make all the difference between the mushroom valve being closed or open, and as this leaves its seat the pump is instantly stopped and as instantly started when it once more returns to its normal position.

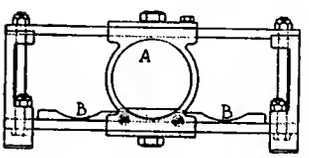
Multiple Worm Drive Axle

Two Direct Speeds and Reverse, Also Direct, Inside Axle Housing

THE illustrations on this page show a multiple worm drive axle giving two direct speeds forward and a direct reverse. The propeller shaft is inclosed within a very large diameter torque tube, and there is an ingenious device whereby the rear end of the shaft can be direct clutched to either of the three worms.

Referring to the cuts which are almost self-explanatory, the upper left shows the layout of the three worms and the triple worm wheel. The lower right view shows the three dog clutches with the propeller shaft in the middle, or high gear position. To change from one gear to another the clutch is thrown out in the usual way, and the action of pressing the clutch pedal also pulls forward the part which slides within the carrier *A*. This disengages the dog clutch and also frees the carrier for transverse movement. The gear lever is then operated, sliding the carrier across till the coupling is opposite either the low speed or the reverse worm, and letting in the clutch then engages the dog clutch before the friction surfaces of the main clutch come together.





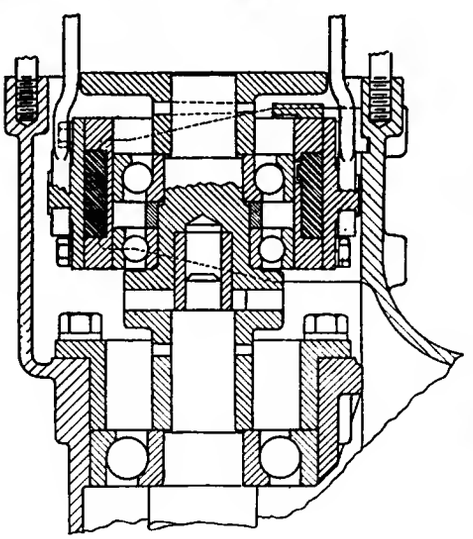
Details of Chase multiple worm drive axle as applied to a Willys-Knight four

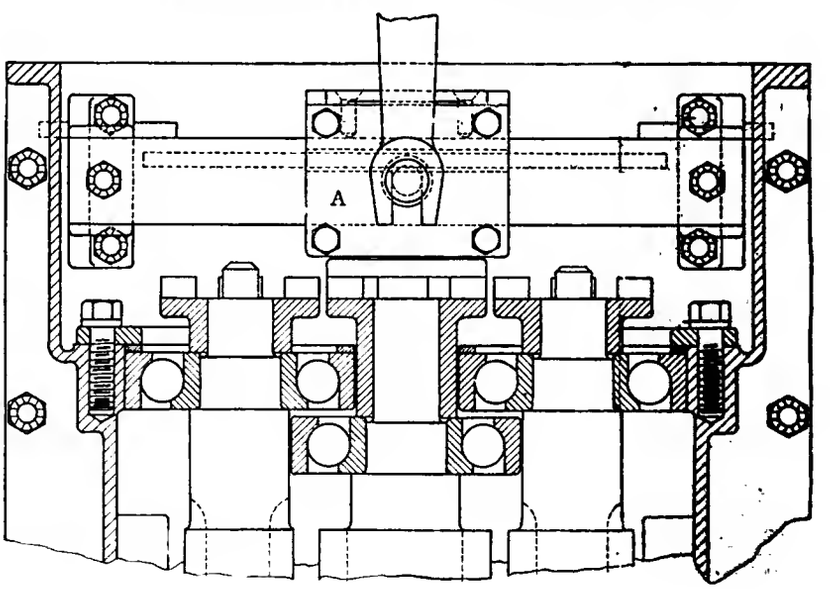
The small drawing at the center shows how the movable carrier is locked, so that it cannot move sideways while the dog clutch is in mesh. The bar *B*, *B* has three semi-circular grooves in it, and the carrier *A* cannot be moved till the clutch has been withdrawn by fully depressing the pedal.

The gear has been made and applied to an automobile. It is the invention of A. W. Chase, and the patents are held by the Multiple Worm Axle Co., whose offices are with those of the Pan American Munitions Co., Grand Central Terminal, New York.

The experimental model, the drawings for which are used for the accompanying illustrations, has been made carefully, and demonstrates in a satisfactory manner. However, it is obvious that some simplification would be possible in designing for regular production, and both weight and size reduced. At present the weight is said to be a little less than that of the original axle with three speed transmission integral.

The fact that all three worms are running continuously is probably of small importance, since there is practically no load on the worms which are running free. The coefficient of friction between a worm and worm wheel is extremely small, and the amount of power required is negligible.



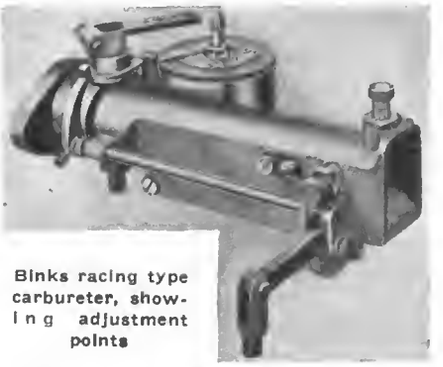


ACCESSORIES

Binks Racing Carbureter

ONE of the features of this carbureter is that the area past the jet may be varied while at the same time keeping the jet in the most constricted area with a wide-open throttle and combining a true venturi action. The instrument is said to impart strong acceleration, rendering gear shifting much less frequent in hill work and providing maximum speed for straightaway travel. There is a pilot jet for very slow running, and starting the engine when cold is made easy, no flooding being necessary, as with the flap drawn up tight fuel will spray out of the main jet owing to the high velocity past it. Under ordinary conditions starting is accomplished on the pilot jet.

Charles Binks, the inventor, is prepared to sell patents and rights of his carbureters for the United States. Binks carbureters are now manufactured in England in various styles for gasoline, kerosene and heavy fuels for both cars and trucks, prices of the instruments varying with their type and size.—C. Binks, Ltd., Eccles, England.



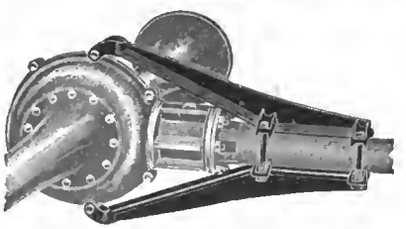
Binks racing type carbureter, showing adjustment points

King Valve-Spring Lifter

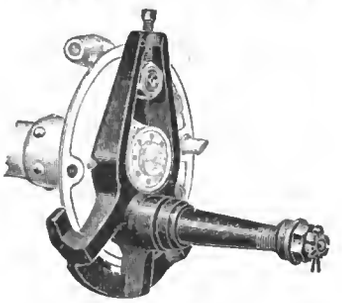
This valve-spring lifter is designed for other than Ford cars. A horizontal member is locked in the valve-cap opening, serving as a purchase for the lever and at the same time holding the valve down from the top. An adjustable chain and ring offer a fulcrum for the notched lever that is caught beneath the valve washer, the washer raised and the locking pin removed. Price, $1.50.—King Specialty Mfg. Co., Brookline, Mass.

Ekern Emergency Axle

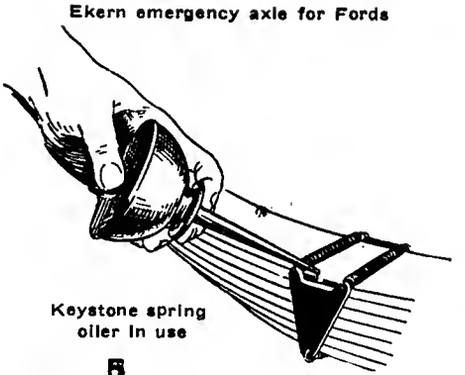
By the use of this device a Ford car with a broken rear axle can be placed on its own wheels and towed home. The emergency axle hooks under the flange on the car-axle housing and is secured by a set-screw at the top. The broken axle stub is then removed from the wheel and the wheel placed on the emergency axle. The axle sells for $5.



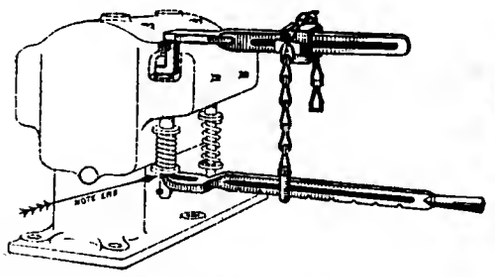
Ekern shaft support for Ford cars



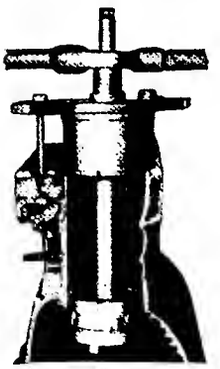
Ekern emergency axle for Fords



Keystone spring oiler in use



King valve spring lifter



Storm & O'Hair reboring tool

Malleable-iron braces are also made for clamping between the end of the drive-shaft tube and the lugs of the differential case, thus supporting the drive-shaft tube of a Ford car. It is stated that the differential housing and the drive-shaft tube are made a unit, thus prolonging the life of the entire rear assembly. The braces may be attached in 10 minutes by any one. Price, $3.50.—Ekern Bros. Mfg. Co., Flandreau, S. D.

Westmoreland Piston Ring

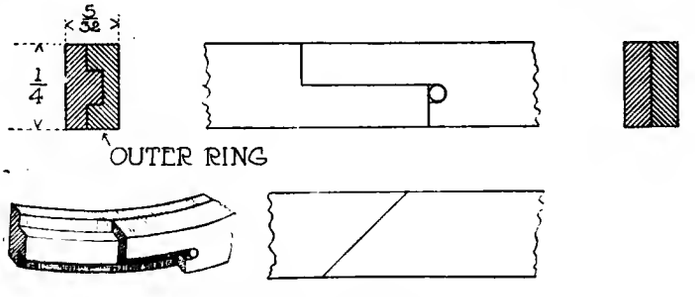
As shown in the illustration, this recently patented piston ring is a two-piece construction, with a lap joint on the outside part and a bevel cut in the inside. The two parts are prevented from moving on each other by the tongue-and-groove feature, while the two joints cannot move around together because of the dowel pin. Some of the advantages claimed are equalized pressure against the cylinder walls, sealed joints, tortuous gas passages, etc. The metal is so distributed as to get equal pressure from each ring. There are no feather edges or excessively thin sections, the inventor stating that there is no chance of wedging between the cylinder walls and the piston and that the ring works equally well either side up.—E. T. Westmoreland, Childress, Tex.

Keystone Spring Oiler

Three coiled springs hold an oil pocket tightly against the sides of the car spring. As the leaves of the spring vibrate with the motion of the car, it is claimed that the lubricant is automatically spread between the leaves. The oiler may be attached to any car, and needs to have the oil supply renewed monthly. Price, 25 cents each.—M. & M. Co., Cleveland.

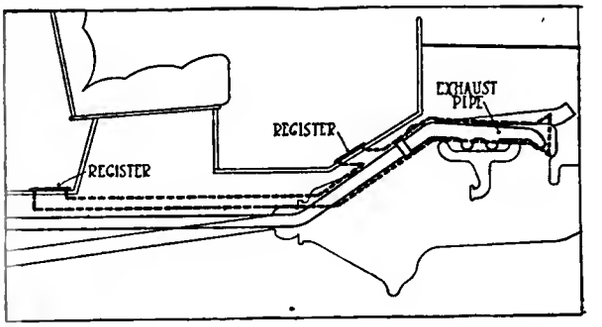
Storm & O'Hair Reboring Machine

In addition to the standard reboring machine adjustable for all makes of engines this company is now manufacturing a special type for Fords, as illustrated herewith. The cutters are universally adjustable by means of a center cutter adjuster and can be set to cut any desired amount. Each cylinder is rebored and finished to any desired oversize in one operation. The machine is simple and accurate and can be operated by hand, low-speed drill press or other power. Parts are interchangeable with



Details of Westmoreland two-piece piston ring construction

At the left is the Ottofy heater attached to an engine, the principle being illustrated in the diagram at the right



those of the standard machine, so additional equipment can be purchased at any time and at moderate cost, to make it suitable for reboring practically all makes of cylinders.—Storm & O'Hair Co., 226 Commercial Street, Thompson, Iowa.

Penfield Spotlight

This small electric spotlight is swiveled on the windshield so as to permit motion in any direction. Two styles are offered, one having a rear view mirror, and the other plain. They are finished in black with polished nickel trimmings. Price, 6-in. light with rear view mirror, $7. Without mirror, $6.50.—Penfield Mfg. Co., Meriden, Conn.

Ottofy Heater

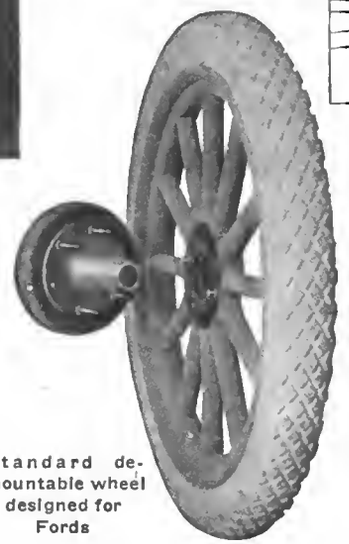
In this device a funnel just behind the radiator catches the air and passes it over the hot exhaust pipes and into the registers in the floor boards. A valve at the mouth of the funnel may be adjusted from the seat, and the desired amount of warm air reaching the registers controlled. Price, large size, touring, $15; roadster, $10; Ford type, touring, $7.50; roadster, $5.—Ottofy Auto Heater Co., 3133 Locust Street, St. Louis, Mo.

Standard Demountable Wheel Set

In converting the regular Ford wheels into demountable and interchangeable wheels, a dummy hub is substituted for the standard Ford hub and carries the wheel by means of four studs and nuts. Flanges are placed on each side of the wheel at the center of the spokes, and are held in place by two bolts. It is claimed that a tire change may be made in 4 min. Price, including a spare wheel, $12. — Standard Auto Accessory Co., Leipsic, Ohio.

Kelley Convertible Truck

For converting a Ford car into a 1-ton truck. After the removal of the body, rear wheels, rear axle, springs and driveshaft, the attachment is bolted on over the Ford frame. It comprises a special lengthened frame, two heavy semi-elliptic springs and a special rear-axle construction, including brakes, and truck wheels carrying Goodrich 32 by 3½ solid rubber tires. The extended wheelbase is 127 in., giving a loading



Standard demountable wheel designed for Fords

space of 9 ft. back of the driver's seat. Various styles of bodies for the truck are also made by this company. Price, internal gear, $365; worm gear, $385.—Kelley Convertible Auto-Truck Co., 332 Michigan Avenue, Chicago.

Pontoklene Polish

Besides acting as a polish for preserving and improving the car finish with little rubbing, Pontoklene acts as a cleanser, easily removing tar, grease and dirt. The preparation is applied by wiping it over the surface to be cleaned and polished, a little rubbing with a thin, soft cloth sufficing to bring up the gloss. Price, $1.50 per half-gallon can, delivered.—Du Pont Chemical Works, Equitable Building, New York.

Lox-It Patch

A combination patch made of strong canvas and rubber. It is applied to the puncture or blow-out cold, allowing ½ to ¾ in. around the hole. It is said that an ordinary repair may be made in 5 min.; that the tube may be used immediately, the puncture being permanently sealed. Price, 6 by 18 in., $1.50; 4 by 16 in., $1; 3 by 17 in., 75 cents, and 2½ by 12 in., 50 cents.—Superior Fabric Patch Co., Midlothian, Tex.

Dutch Brand Varni-Brite

This compound is claimed to restore discolored varnished surfaces to their pristine brilliancy. When the car is new the original luster is preserved. The line is very complete, including a top dressing, a cushion coating paint, a black brass lacquer, and a rim paint, as well as many other products for grooming the car.—Van Cleef Bros., 7711 Woodlawn Avenue, Chicago.

Industrial Miscellany

Factory

Robert H. Hassler, Inc., Indianapolis, Ind., manufacturer of automobile accessories, yesterday announced the completion of a modern manufacturing plant on a 6-acre site which will be occupied by the recently incorporated Hassler Motor Co., which has a capitalization of $200,000. The new company, which expects to be in operation shortly after the first of the year, will manufacture a car of medium price, which will be placed on display for the first time at the Chicago show.

American Appliances & Machinery Mfg. Co., Brooklyn, N. Y., will occupy its new building at 161 Jamaica Avenue, on or before Jan. 1.

Fuller & Sons Mfg. Co., Kalamazoo, Mich., will erect a four-story 180 by 60-ft. addition to its plant. This will practically double the plant and increase output by more than 100 per cent.

Oliver Rubber Mfg. Co., Oakland, Cal., is erecting a new building fronting at Broadway and 21st Street, with 10,000 ft. of floor space. The company will enter the tire manufacturing field with a capacity of twenty tires daily. A specialty will be made of large size tires.

J. P. Gordon Co., Columbus, Ohio, maker of fabric goods, has been compelled to put on a night shift of over 200 power sewing-machine operators and will add to this as rapidly as new operators can be secured and trained.

Personals

W. G. Fuller, New Orleans, La., has been made sales manager of the Capital City Auto Co., Studebaker agent.

L. G. Fairbanks has become eastern district manager of the Firestone Tire & Rubber Co., Akron. He was formerly assistant advertising manager of that company. He succeeds D. C. Swander, who goes to Boston as local Firestone manager.

Fred Brandt has joined the staff of the Princess Motor Car Co., Detroit, Mich., as master electrician in charge of the electrical department. Mr. Brandt was formerly electrical expert for the Hupp Motor Car Corp.

G. E. Rason has resigned from his position as advertising manager for the Ford Motor Co., of Canada, and will join Frederick K. Stearns & Co. as assistant manager.

H. L. Walker Co., Detroit, Mich., distributor for the Woods electric in Detroit, will also handle the agency for the Princess Motor Car Corp. for Wayne, Oakland, Monroe, St. Clair, Macomb and Washtenaw counties.

Frank C. Riggs has been appointed general manager of the Pacific Coast territory of the Willys-Overland Co., succeeding A. D. Plughoff, who recently resigned. He has been president of the Oregon Motor Car Co. up to the time of this change.

R. B. Johnston has joined the American Motors Corp., Plainfield, N. J. He will help secretary P. W. Hansl in handling the advertising and assist director of sales I. Brock in his work. He started the automobile column of the New York *Sun*, ran *Leslie's* Motor Bureau for some time and gained valuable merchandising experience while working for Carl H. Page, E. R. Hollander, Harry W. Ford and the Chalmers company.

R. R. Price, formerly distributor of Chalmers cars at Jacksonville, Fla., has joined the tractor manufacturing business with which Carl G. Fisher and C. G. McCutcheon are associated.

A. G. Henderson, of Walla Walla, Wash., has been appointed the Detroiter

distributor for that section by the Detroiter Motor Car Co.

J. R. Fry, has been made the manager of the Becker Motor Car Co., Grand Rapids, Studebaker distributor. Mr. Fry was formerly in the wholesale department of the Studebaker Corp., Detroit.

Joseph Sairs, Ford dealer at Beloit, Wis., is preparing to establish a plant for the manufacture of brake linings, specializing in such supplies for the Ford. Mr. Sairs has purchased a site and plans to erect a two-story factory, 50 by 160 ft. Work will begin about March 15.

M. L. Helmka has been appointed superintendent of the painting department of the Buick Motor Co., Flint.

R. W. Donohue has been appointed in charge of the sales promotion department of the Regal Motor Car Co., Detroit.

Don M. Dickinson has been made director of sales of the Champion Motors Co., Fulton Ill., and Cleveland.

R. W. Lytle, formerly engineer and production manager of the Bimel Automobile Co., Sidney, Ohio, has been made production manager of the Rock Hill Buggy Co., Rock Hill, S. C.

F. F. Tilden, formerly city salesman at the Indianapolis branch has been installed as manager of the Goodyear branch at Columbus, Ohio, succeeding W. W. Magill, whose duties are to be announced later. W. S. Boone, formerly branch manager at Scranton, Pa., has been made supervisor of city sales at Philadelphia. W. G. Starnes has been made manager of the Atlanta branch, succeeding J. E. Taylor, who has been transferred to the dealer's help division of the automobile tire department at Akron. F. W. Nason, formerly manager of the Rochester, N. Y., branch, has been transferred to the export department at Akron.

J. T. Belanger, Detroit, has become Wayne County agent for the Olympian car, and has formed the Olympian Motor Sales Co.

Joseph Gardham has rejoined the forces of the Chalmers Motor Co., Detroit. He was connected with that company during the days of touring competition, and drove in several trips for the company in pathfinding.

G. F. Hare has joined the Van Cortlandt Vehicle Corp., New York distributor of the Peerless cars and trucks. He has been with the automobile industry for 15 years. For the last 3 years he has been with the Chevrolet company. W. J. Lasher, for the past 4 years district sales manager of the Mitchell Motor Car Co., has also joined the company as district manager.

Hoover Holton has been promoted to zone manager of New England for the Maxwell Motor Co., Detroit.

C. L. Guyman has been promoted to assistant truck sales manager of the Packard Motor Car Co., Detroit. He was formerly in charge of the field representatives.

W. H. Taneyhill has been appointed district manager for the Scripps-Booth Corp., Detroit, succeeding J. E. Morehouse who has been promoted to manager of the local retail store.

W. L. McCabe has been elected secretary and treasurer of the Brewer Motor Car Co., Spokane, Wash. He was formerly office manager of the firm.

Norman DeVaux has been elected general manager of the Chevrolet Co. of Cal., and D. C. Durant has been appointed sales manager of the company. Mr. DeVaux and Mr. Durant were formerly sales manager and assistant sales manager of the company, respectively.

Dealers

Carl M. Green advertising agency has opened an office in Chicago, from which it will handle the advertising account of the Nash Motors Corp. Hal Trump and Owen B. Winter, both former Detroiters, will operate the office.

Not King Factory Branch.—In THE AUTOMOBILE for Dec. 7 it was stated that the King Motor Car Co. had leased premises at 2813 Locust Street, St. Louis, vacated by the Brinkman Motor Car Co., for factory branch. Our correspondent was misinformed, as this is not a factory branch.

Maxwell Motor Co., Inc., will erect an assembly and distributing plant at Minneapolis which will cost $300,000 and will be four stories high and 132 by 330 ft. in size. It is expected that the building will be ready for occupancy and will employ approximately 200 men.

Jennings Motor Sales Corp., New York, has taken the distribution of the Hal.

Fentress Motor Car Co., Seattle, has moved into quarters at the corner of East Pine Street and Tenth Avenue. It will handle the agency for the Peerless.

Adams-Oakland Co., Cleveland, agent for the Oakland and Premier, has leased a two-story building which is to be fitted into a complete automobile sales room and service station. Mr. Adams states that the structure will be occupied by the Ohio Auto Sales Co., which handles the Oakland and Premier cars.

J. Q. Goudie, of Detroit, has been appointed the Michigan agent for the Pennsylvania Rubber Co.

Axel Anderson, president and treasurer of the Union Chain Co., Minneapolis, has bought the interests of F. A. Gahring and will continue adding new machinery and factory improvements to increase the output.

Willys-Overland Co., Minneapolis, has opened the new Northwestern retail sales department and show rooms at Hennepin Avenue and Harmon Place.

Acme Auto Truck Sales Co., Minneapolis, has opened an agency at 917 Hennepin Avenue.

Carlson Motor Car Co., Minneapolis, has opened salesrooms for the KisselKar in a new building at 1626 Harmon Place.

J. F. Lynch, St. Paul, former agent for the Kissel Kar, has been made sales manager for territory east of the Mississippi River.

W. H. Ryan, Wilmington, Del., has taken the agency for Norwalk tires and tubes.

White Brothers, Wilmington, have taken the agency for the International truck.

N. B. Stapleford, Delaware City, Del., has taken the agency for the Grant cars in New Castle County and northern Kent and for the Oldsmobile in the State south of Wilmington.

Consolidated Auto Co., Spokane, Wash., has taken the Eastern Washington agency for the Dixie Flyer cars and the Old Hickory truck.

F. P. Fentress has taken the Seattle, Wash., agency for the Knight tire.

Saunders Motor Car Co., Birmingham, Ala., has severed connection with the Hudson Motor Car Co. and has taken the agency for the Westcott.

Brown & Holland Magneto & General Repairing Co., Little Rock, Ark., has opened for business. In addition to parts for all starting and lighting systems, the company will make good guarantees on Bijur starters and Bosch magnetos.

Cadillac-Stout Co., Memphis, Tenn., has been organized to sell the Cadillac cars. J. A. Stout, formerly of Nashville, is the active partner. Temporary headquarters have been opened at 247 Monroe Avenue.

Independent Tire Co., Columbus, Ohio, has opened a branch at 336 Monroe Avenue, Memphis, Tenn., for the sale of factory seconds. J. E. Leacy, Southern manager, is in charge and will make the branch his headquarters.

Virtue & Liberty Motor Sales, Ltd., Toronto, Ont., has taken on the Ford.

Jubilee Spark Intensifier Co. of Canada, Winnipeg, Man., is handling the Jubilee spark intensifier.

McCurdy-Brainard Company recently established agents in Philadelphia for the Jordan car, has acquired selling rights in this territory for the Maxfer truck.

City Garage, Burlington, Col., Studebaker dealer, has added the Aurora demountable truck agency for Kit Carson County.

Woods-Premier Motor Co., Denver, which recently opened a Premier distributing agency for Colorado and part of Wyoming and New Mexico, has secured the Stewart truck.

V. S. Allen, Longmont, Col., has taken the Aurora demountable truck agency for Boulder County.

Harrison Motor Co., Denver, a new $10,000 corporation, has secured the distributing agency for Colorado for the Liberty and for Northern Colorado and Wyoming for the Jordan, and has opened a salesroom at 222 Sixteenth Street.

Lamar Hardware Co., Lamar, Col., has taken the Aurora truck agency for Prowers and Baca Counties.

Highway Auto Sales Co., Denver, Crow-Elkhart and Argo distributor for Colorado and Wyoming, has gone out of business.

Chandler Agency & Service Co., Greeley, Col., Chandler and Elcar dealer, has added the Aurora demountable truck agency for Weld County.

Colorado Motor Truck & Service Co., Denver, has secured the Service truck for Colorado, Wyoming and New Mexico.

Toliver Punctureproof Tube Co., Denver, has opened a salesroom and shop at 1322 Broadway.

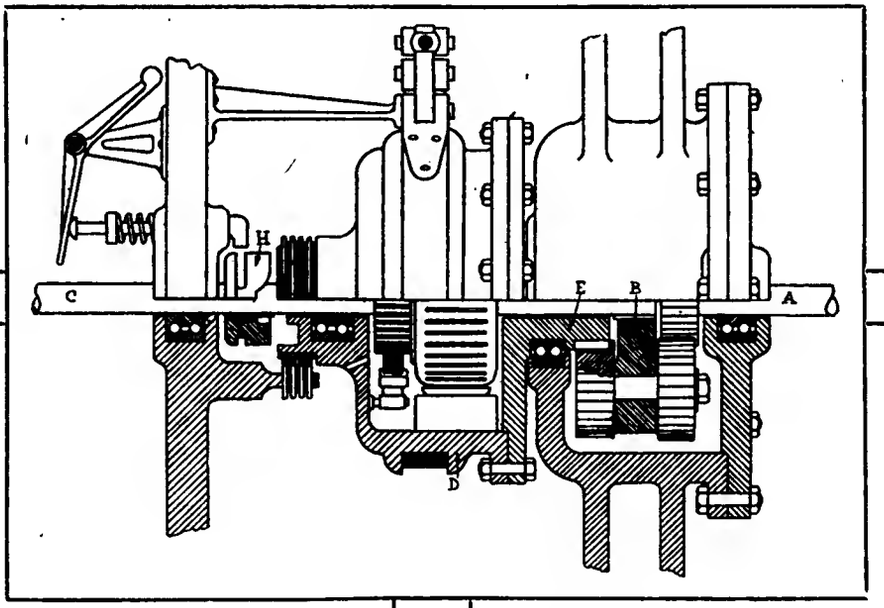
Mid-West Rubber & Auto Co., Denver, Davis distributor for Colorado and part of New Mexico, has moved to 36 East Twelfth Avenue. It has given up the Pennsylvania tire distributing agency for Colorado and will sell cars exclusively.

Merrick Motor Co., Denver, has opened the Crow-Elkhart distributing agency for Colorado and Wyoming.

De Luxe Equipment Co., Denver, has opened a distributing agency for Colorado, Wyoming and New Mexico on the De Luxe body for Ford cars.

Mollman-Mulconnery Motor Co., Denver, has secured the Apperson distributing agency for Colorado, Wyoming and New Mexico.

Flexible Transmission of Power Is the Great Objective of Automobile Manufacture



The Automobile Manufacturer has here an opportunity to obtain exclusive use of an original and effective Electro-Mechanical Transmission by co-operating with the inventor on a royalty basis.

This opportunity is not to be treated lightly. Every manufacturer knows the keen competition for selling features which exists in the automobile world today. Nothing makes a car more significant to prospective buyers than mechanically sound innovations in the power plant developing more flexible transmission of power.

He also knows that everything points to the fact that electro-magnetic transmission will be the big selling feature for several seasons to come. It is not unlikely that the old style transmission will be gradually displaced by the more sound of the electro-mechanical devices.

Here is a chance to put yourself in a position to reap the full benefit of this movement.

The model illustrated and described is merely the simplest expression of the device. It can be directly and easily developed by variations in detail into as complete, efficient and flexible a transmission as the most exacting car owner could wish. Invented and owned by

MR. CARLOS M. SEIDEL
Address care of The Automobile

Mr. Seidel's Electro-Mechanical Transmission has two special advantages: it gives a direct drive on high gear, both electrical and mechanical portions being then inoperative; and it requires for the electrical portion only one-half of the horsepower of the gasoline engine.

The operation of the transmission can be understood by a reference to the diagram in which A is the engine shaft. This drives the sun wheel of a planetary gear. B is a pinion carrier fixed to the shaft C, which is the driven shaft to which the universal joint is attached for the propeller shaft. The field magnet D turns freely from the shaft C, to which the armature of the electrical machine is fixed. The second sun wheel E is integral with the field magnet D and connects it with the engine through the medium of the planet pinion which are both solid on their shafts.

Now when A is moving and B stationary, the pinions will revolve and the sun wheel E will be driven in the same direction as the engine is revolving at a speed depending on the number of teeth in the sun wheels. The field magnet integral with E, revolves around the armature, and as soon as the current is allowed to flow there is an inter action between the magnetic field and the armature, causing the magnets to drag the armature round with them. This is equivalent to applying a magnetic clutch to the shaft C, tending to start the car.

But there is the reaction to be considered. When the shaft C is turned, the pinion carrier B revolves with it and because of the resistance of the armature which tends to hold back the field magnets and the sun wheel E, divides the driving effort equally between the armature and the planetary gearing.

As the car speeds up we reach a position where the shaft C is revolving a little slower than A, the difference in speed being only sufficient to maintain enough current to supply the necessary magnetic grip.

When this happens the dog clutch H is moved locking D to the shaft C. Then the armature and field magnet are revolving at the same speed and no current is being generated, and there is no relative motion in the planetary gear. The car is running on direct drive.

To obtain a reverse, a brake is applied to D stopping it from rotating and causing the pinion carrier and the shaft C to revolve in reverse directions.

If electric connection is made between the storage batteries and the electrical machine it can be used as a starting motor for the engine.

When the engine is idling the unit can be also used through the means of a voltage regulator to boost the charge of the storage battery.

Thus the one electric unit offers possibilities as a clutch, as a starting motor and as a charging dynamo.

MERCER MOTOR CARS

22-73 Series Mercer Motor Cars

IN spite of the abnormal conditions existing in the material market, the 22-73 models are absolutely held to the high standard of construction for which Mercer cars have long been recognized. No compromise of any kind has been allowed, even in the most minute detail.

Consistent with the established Mercer policy of building only a limited number of highly developed, medium-weight, *four-cylinder* cars of known quality, this latest series of cars represents our best efforts toward what we consider an "ideal" car honestly built and honestly sold.

You will better appreciate simplicity and dignity in automobile construction if you visit the Mercer Exhibit at the Shows

CLEVELAND—December 30 to January 6 **PHILADELPHIA—January 12 to 20**
NEW YORK—January 6 to 13, Grand Central Palace, Space B9—Second Floor
CHICAGO—January 27 to February 3, Coliseum, Space P1

MERCER AUTOMOBILE COMPANY **Whitehead Road, Trenton, N. J.**

When an insignificant little bronze bushing wears out—

It causes rattles or knocks, vibrations or lost power and invariably results in expensive overhauling and temporary loss of the car.

Any repairman who replaces worn bushings with bushings of ordinary bronze runs the risk of causing the owner an amazing amount of trouble and expense.

The choice of a proper bearing metal for bushings may seem, at first glance, to be a matter of small importance, but when you consider the expensive and disastrous results that may follow through the use of bushings of questionable or unproven merit, then the matter assumes vital and paramount importance, both as concerns the owner's pocketbook and the repairman's reputation.

If you have reason to believe that your repairman is both experienced and conscientious, you can safely depend upon him to overhaul your car with bushings made of highest grade bronze.

But if you have any reason to believe that he does not regard the bushing problem as serious, then, for the sake of your pocketbook and your future peace of mind, insist upon him using Non-Gran.

By so doing you will save hundreds of dollars in future repair bills because your car will be equipped with the same flawless, long wearing bushings that enable quality-built cars to deliver from two to five times the service of ordinary cars.

Non-Gran differs radically from all other bearing bronzes.

Non-Gran excels any known metal used for bushings in its combination of wear-resisting qualities, toughness, unfailing uniformity, molecular cohesion and freedom from flaws.

Practically all manufacturers of high-grade cars and motors make their bushings of Non-Gran.

These men know that a car can last only as long as its wear-subjected, non-adjustable bushings. Consequently, they take no chances but use the best metal they can get—Non-Gran.

STAR HAND-MADE TIRES

Are You Ready To *Control* the Sale in Your Territory!

The successful tire merchant of tomorrow must absolutely control in his territory the selling of the goods he offers and be in a position to make a profit consistent with his efforts. The margin of profit now received from the quantity tire manufacturer does not exceed the overhead expenses of a well conducted distributing agency and he finds himself simply swapping dollars with the manufacturer. More and more service is being demanded by the tire buyer and in order to extend this necessary service the dealer must receive a larger margin of profit.

During 1917 it is estimated that over $350,000,000 will be spent in the purchase of tires for pleasure cars alone. It will be the golden opportunity for the beginning of a permanent business with continuous profit for tire dealers who sell the right tire at the right price and with a substantial net profit. Our organization has established a fixed policy for selling its entire output through

Exclusive Dealers

There will be no branches and we offer a most unusual proposition for the dealers who become associated with us for putting unlimited effort behind their sales—receiving in return absolute territorial protection.

The **"ALL STAR"** tread (and its kindred styles) promises to be a sensation in the tire field and will be produced by Akron's most experienced capital, its best manufacturing brains and by the most expert labor with years service in the perfection of tire making.

If you are ready to accept this exclusive agency for the newest **Star** in tiredom, write us immediately. We pledge you the most liberal proposition ever made to tire dealers; we pledge the men who buy a better tire—a value received in full; and the most perfect tire that money, brains, material and workmanship can build. The various styles of tires and tubes will be complete and with

5000 MILES GUARANTEED SERVICE

Quick action necessary to secure your territory.

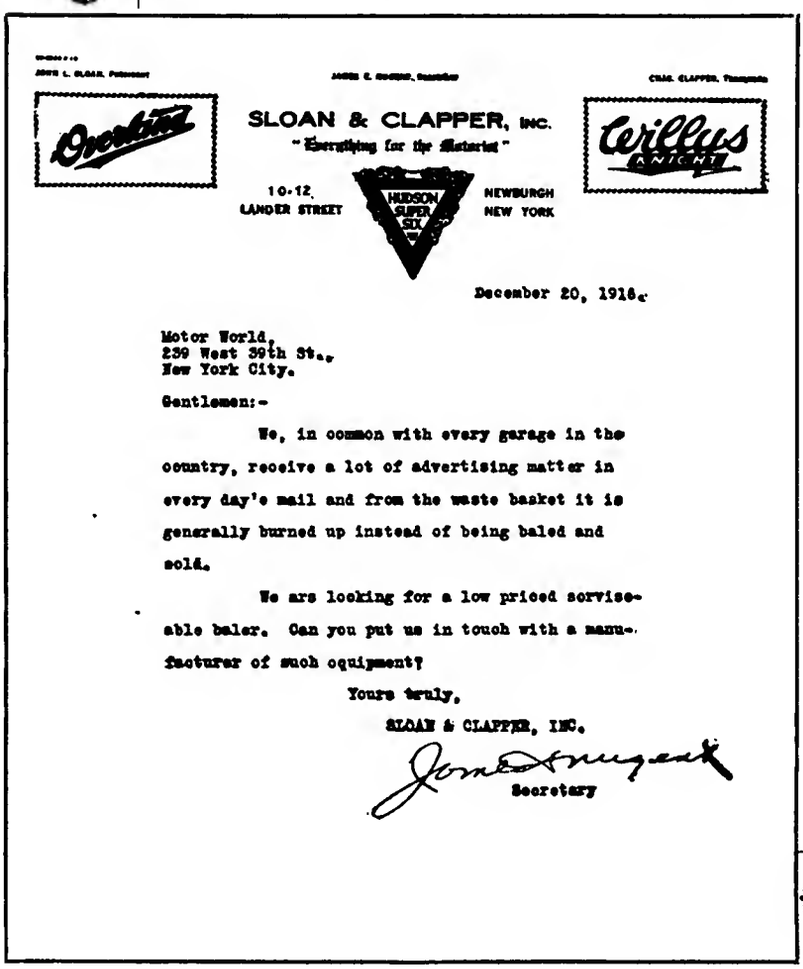
What Constitutes 100 Per Cent Business Success?

(1) To produce an article that is salable	40%
(2) To organize channels for selling and distribution	25
(3) To create demand that will absorb the product, with a fair percentage of profit for the manufacturer	35
	100%

The advertising man represents 35% in the success of every business. Greatest success in the car and accessory industry is where the advertising man lives up to the limit of his possibilities—where he measures up to the full 35%.



SLOAN & CLAPPER, INC.
"Everything for the Motorist"
10-12 LANDER STREET NEWBURGH NEW YORK

December 20, 1916.

Motor World,
239 West 39th St.,
New York City.

Gentlemen:-

We, in common with every garage in the country, receive a lot of advertising matter in every day's mail and from the waste basket it is generally burned up instead of being baled and sold.

We are looking for a low priced serviceable baler. Can you put us in touch with a manufacturer of such equipment?

Yours truly,
SLOAN & CLAPPER, INC.
Secretary

The advertising man has two major responsibilities: (1) to prepare forceful and impelling "copy," and (2) to present that copy to potential purchasers in such manner as will insure direct interest in the product advertised by those to whom the copy appeal is directed.

The reproduced letter on this page bears a significant message to those advertising men who are anxious to become 35 per centers. It proves the unwisdom of contributing to that seemingly inexhaustible flood that goes over the desks and into the waste baskets in thousands of establishments in every section of the country.

And now that we have given you the more important facts about the AMERICAN SIX, let us tell you something of the Sales Policy behind it

LIKE the car itself, the sales policy behind the AMERICAN SIX has been carefully developed by men of experience who are using all the lessons of the past to provide the largest and most permanent satisfaction for the future. Three cardinal principles will dominate the selling policy of the AMERICAN SIX.

FIRST—*To build up a real Merchandising organization*—an organization of automobile merchants who recognize opportunity, know possibilities, and look to the future not less than the present. In the AMERICAN SIX Dealer-organization the man counts most. Ample capital and complete sales arrangements have their places in our estimation but they are secondary to the integrity and intelligence of the man.

SECOND—*To create a permanent organization. From the* profit standpoint permanence is as vital to you as it is to us. We are building an organization for tomorrow as well as today, and we want our Dealers to share in all the future profits to be derived from the increased sales and production of the AMERICAN SIX. We will stand by our Dealers.

AND FINALLY—*We propose to co-operate with our sales organization to the best of our ability.* We recognize that the Dealer is the best judge of sales conditions in his territory and therefore we cannot do his selling. But, in-so-far as we can, we will lend our aid and co-operation in service and merchandising. To this end an extensive advertising campaign in the *Saturday Evening Post* and other influential national publications is already under way, and by every other effective means this Company is pledged to put its full resources behind its Dealers.

New York Show
4th Floor D1 & D2

Chicago Show
Greer Building G12

To a Limited Number of automobile merchants whose ideas harmonize with ours and who see in the AMERICAN SIX a permanent and profitable opportunity we are now ready to offer a contract for its sales representation.

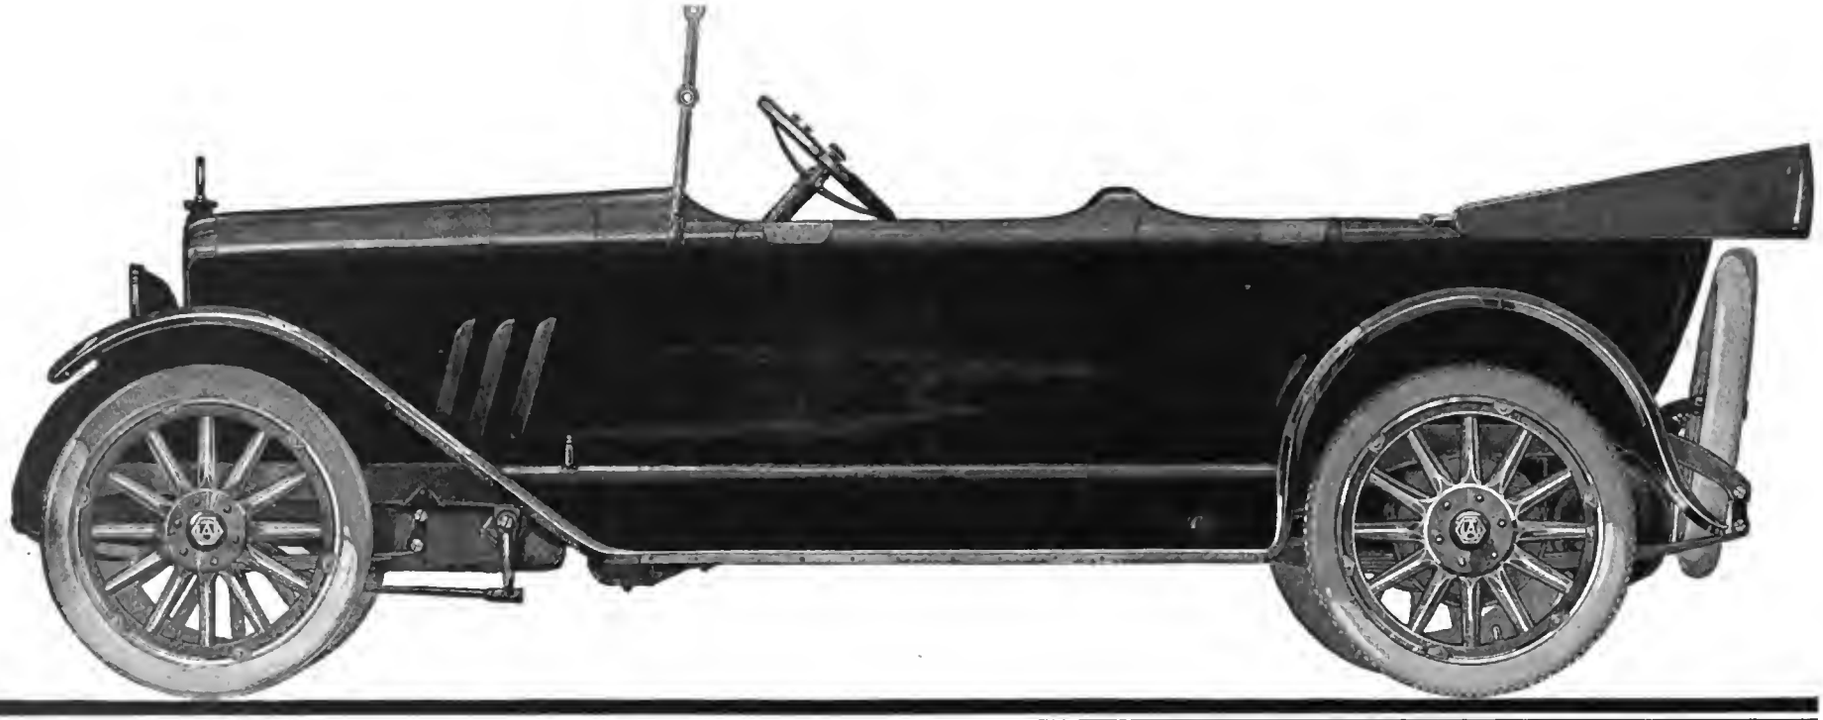
We will build only 3000 cars this season. You may have your share of this total—provided you act promptly. Applications for territory will be considered in the order of their receipt.

Production of the AMERICAN SIX is so far advanced that we can assure deliveries in quantity by January—demonstrators immediately.

The AMERICAN SIX will be displayed at the New York and Chicago Automobile Shows. Reservations of Territory may be entered now.

A Car to Compare with Costlier Cars

AMERICAN SIX $1285



A Car to Compare with Costlier Cars

AMERICAN SIX

IN THESE DAYS almost any automobile manufacturing concern can sell its *first year's* output. The real test comes in the *second* year. If the car is right, if its performance measures up to its promise, other things being equal, it will have a *good* second year—and just as likely many better years to come. But if it doesn't meet the test, look out for trouble. *The AMERICAN SIX is built for the Second Year.* Looking at it, you say "This is a *fine*-looking car." But there is more to it than looks. Down inside, where the wear and tear comes, it is built right. Mechanically and structurally, it is as good as it looks.

And the *Reason* is this: The AMERICAN SIX was planned and is built by *men who know;* there has been no guess work in its development. Behind it is an organization of engineering and manufacturing experts whose skill and ability are known and recognized wherever automobiles are made. This is a sure guaranty that the AMERICAN SIX is not only a good-looking car but is also a *perfect mechanism,* smooth running and efficient in operation.

And it is to this fact that we look for *bigger* sales the SECOND year and in all the years thereafter.

A car is only as good as its engine

The AMERICAN SIX power plant is a revelation of efficiency. The motor block casting—suspended at three points—is designed for even cooling of *all* parts of the cylinder walls by having water surrounding each piston pocket. The 1 9/16 inches valves are a size usually found only in far larger motors, and the valve seats are so thoroughly water-cooled that pitting is made impossible. The 1¾ inches crank-shaft revolves on three wide plain bearings. The circulating splash type lubrication is certain and positive. Oil is easily put into the engine base through the accessible breather top. The water-pump, distributor generator and tire pump are driven by one shaft. To assure lightness the upper portion of the motor casting is aluminum and the base pressed steel. The bore is 3 inches, the stroke 5 inches. Heated air enters the Zenith carburetor and the vaporized fuel is sent directly into a manifold integral with the engine block. In operation this powerful and efficient motor, built under the immediate direction of the engineers of the American Motors Corporation, is quiet and smooth running, flexible and economical in the consumption of gas. It puts the AMERICAN SIX in a class by itself.

Brief Particulars of the AMERICAN SIX

EQUIPMENT:—Engine-driven tire pump; Boyce motometer; one-man top, quick detachable curtains; rain-vision windshield; dash lamp lighting speedometer, ammeter, carburetor adjustment, lighting and ignition switches; starter button on toe-board; button of motor-driven horn at steering wheel center; complete set of tools.

GASOLINE SYSTEM:—Tank at rear and Carter gravity tank over engine.

RADIATOR:—Cellular, shallow but high and broad.

IGNITION:—Generator-storage battery, Gray & Davis coil and distributor.

ELECTRICAL SYSTEM:—Gray & Davis two-unit, starting motor has Bendix drive to fly wheel, generator on pump shaft, 6-volt, 100 ampere hour Willard battery; double bulb headlights, wiring of one-wire type.

CLUTCH:—Three dry-plate discs, ball bearing throw-out collar.

TRANSMISSION:—Selective sliding gears, three speeds and reverse.

AXLES:—Front, one-piece drop forged I-beam; rear, three-quarter floating, spiral bevel gears, gear ratio, 4 5/12 to 1.

WHEELS:—32″ with 4″ straight side tires on demountable rims, extra rim in tire carrier at rear.

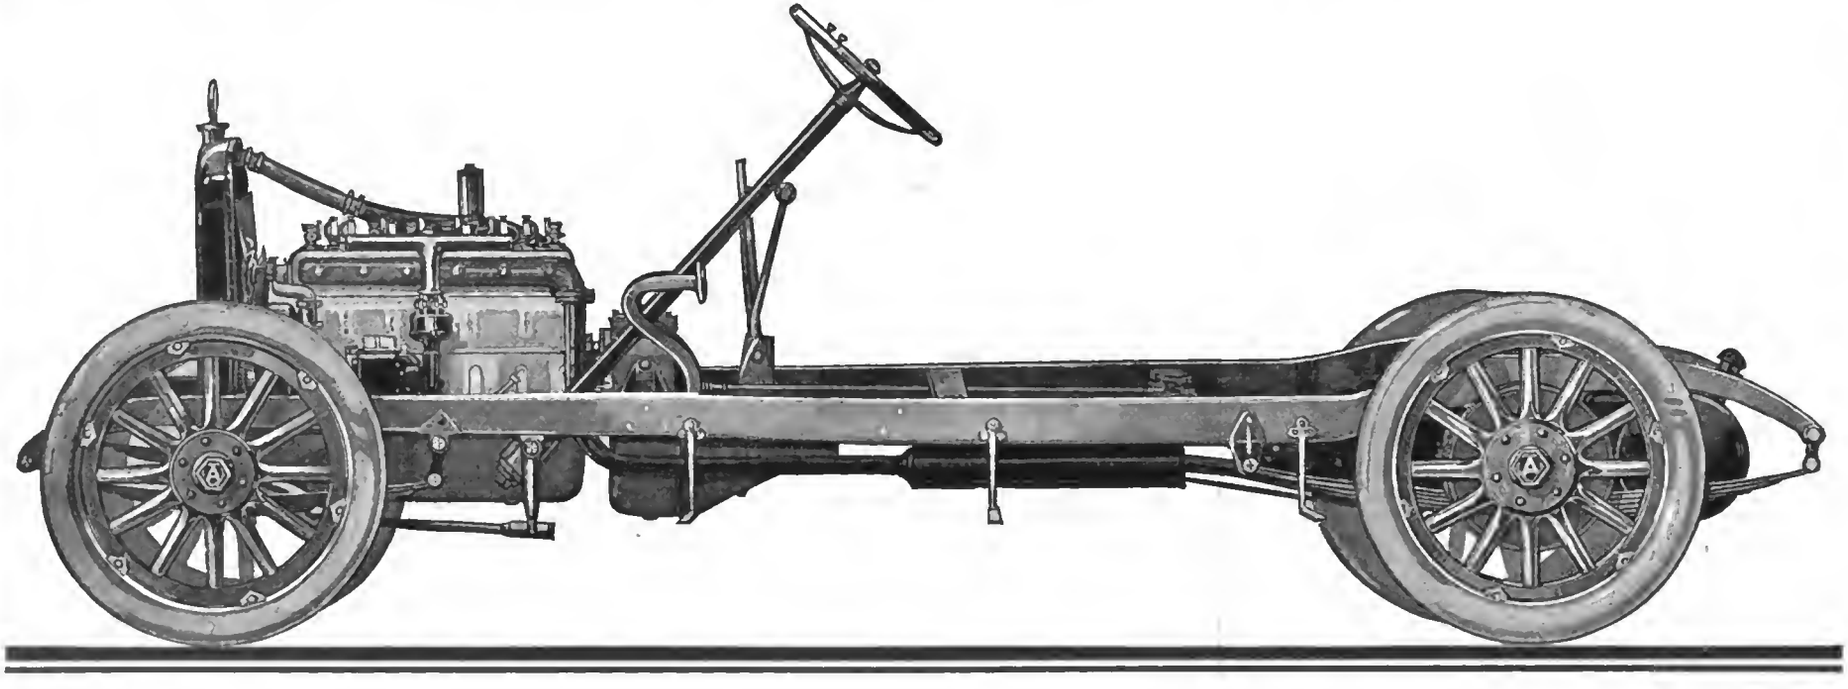
WHEELBASE:—122″; tread 56″.

BRAKES:—On rear wheels; hand emergency expanding, foot service contracting, drum 14″ diameter, 2½″ wide.

SPRINGS:—Semi-elliptic, front 38″ x 2″, rear 52″ x 2″, Hotchkiss drive.

CONTROL:—Left drive, center control.

WEIGHT:—Car and equipment, 2700 pounds distributed equally front and rear.



WHEN you are going into business with other men it is a good plan to know who they are. These three men are a big part of the organization that builds and sells the AMERICAN SIX. There are other good men in the American Motors Corporation but, first of all, you will want to know Speirs, Chevrolet and Brock

PRODUCER

JOHN C. SPEIRS, General Manager and Construction Engineer, is recognized in the automobile industry as "a man who makes a reality out of visions." He is a practical plant executive of vast and diversified experience without a superior—and mighty few equals—in the entire motor vehicle field. Speirs knows thoroughly every best method of making an automobile that gives service and lasts long. From the inception of automobile building in this country he has been directing the work of men and building the materials that went into the making of good cars—Locomobiles, Autocars, S. G. V's and Mercers—and his ripe experience is entirely at the command of the AMERICAN SIX. Speirs is in direct charge of the factory and all matters of production.

ENGINEER

LOUIS CHEVROLET, Vice-President and Chief Engineer, is widely known as an automobile expert and engineer. His technical knowledge and training have been enriched in that severest laboratory of automobile engineering—the racing course, where he won his early fame. He is the holder of many famous trophies, having finished in first place ten times out of twenty-five starts in national road races since 1909. In the course of this experience Chevrolet has racked automobiles over rough roads and smooth, to the tops of mountain peaks, and at breath-taking speed over all sorts and conditions of speedways and dirt tracks and, although his personal interest is largely confined to automobile construction, even now he occasionally takes his place at the wheel in important racing events.

MERCHANDISER

MARCUS I. BROCK, Director of Sales, is one of the business veterans of the great—although young—automobile industry in this country. He had charge of the sales department of the Autocar Company in the earliest days of motoring in America. He also performed a similar service for the E. R. Thomas Company and for some time was Assistant General Manager of the Association of Licensed Automobile Manufacturers. Brock is known to the trade as a builder of dealer organization—not as a driver—in his relations with merchants who have been agents for the cars he was selling. And in his present capacity he is welding together a permanent selling organization of automobile merchants who look to the AMERICAN SIX for fair dealing and substantial profits now and in the future.

To Dealers

AS stated on the first page of this announcement, applications for the limited territory to be allotted for the AMERICAN SIX are now being considered. You will have ample opportunity to see the AMERICAN SIX at the NEW YORK and CHICAGO AUTOMOBILE SHOWS, but reservations of territory may be entered now. Address all communications to MARCUS I. BROCK, Director of Sales

Driving Through Air ~

What Makes the Owen Magnetic Run So Smoothly?

Men who have ridden in Owen Magnetic cars owned by their friends are constantly coming to us asking, "What makes this car FEEL so differently in the way it rides? What makes it FLOAT along the road as though it were being drawn forward by some force outside of itself?"

The answer is, because when you ride in an Owen Magnetic, you are driving by magnetism through air space.

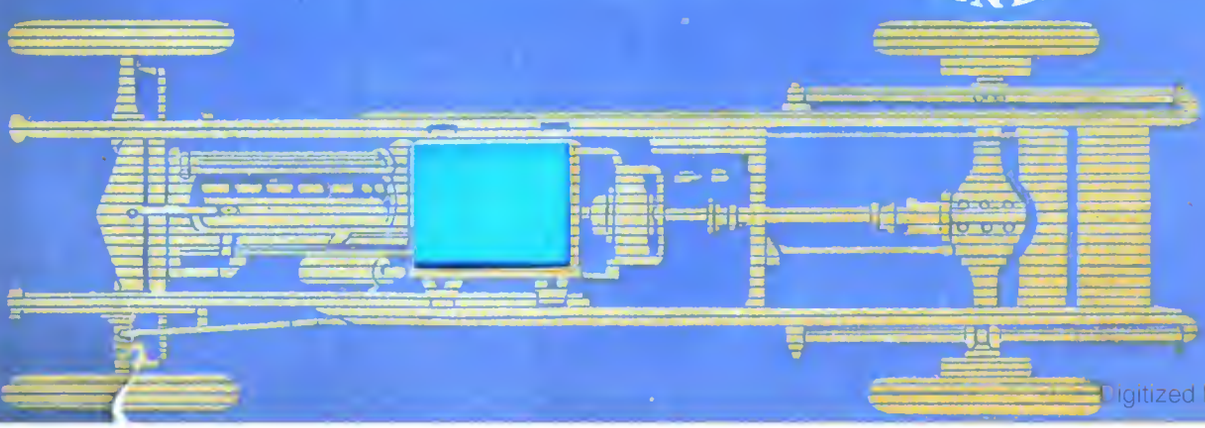
Unique Comparisons

By referring to the drawings at the bottom of these pages you will see that we have an explanation of the operation of this transmission as it appealed to a youth of fifteen. Here is shown a magnet mounted on a pedestal that can be revolved by its hand crank. Between the ends of the magnet a piece of steel attached to a shaft is mounted on a similar pedestal.

The Cause of Smooth Action

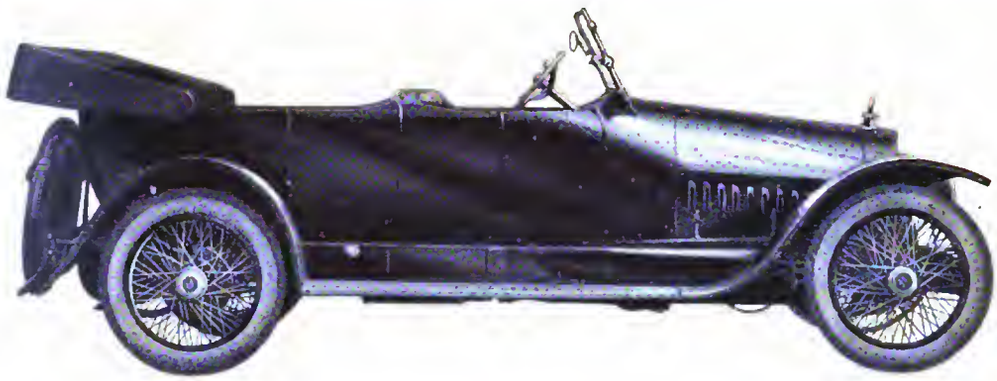
Now if you turn the hand crank and so revolve the magnet you will find that the piece of steel also revolves, although there is an air space between the steel and the magnet. You will notice that even if you should start the hand crank

OWEN MAGNETIC



Here you see the princi ple of the Owen Magneti Transmission reduced t its simplest form. A magnet turning a piec of steel with it, as it re sponds gradually to it magnetic power.

DRIVING THROUGH AIR



with an abrupt jerk, the piece of steel would not start with a jerk, but will begin to move gradually, starting with an imperceptible gradation of movement—so gentle—so slight—that the eye scarcely can register it. That is because there is no rigid mechanical connection between the magnet and the steel—because the steel is revolved by an invisible, intangible magnetic force flowing across an air space.

The Mission of the Magnet

Now turn again to the illustration at the bottom of the page and you will find instead of a hand crank to revolve the magnet, we have a gasoline engine. Then note that the piece of steel is still between the ends of the magnet, but is now mounted on the drive shaft of the car. Here you will see that the engine revolves the magnet, the magnet revolves the steel, and of course revolves the drive shaft with it—and you will see also that when the magnet revolves, although it may start with a jerk, the piece of steel—and therefore the drive shaft—cannot start with a jerk, but will be gradually, softly drawn around with an imperceptible motion by this elastic magnetic field acting across an air space. You will note that there cannot be a sudden jump in driving effort from engine to drive shaft, to rear wheels, to tires, as when the clutch is let in and a rigid connection made between power plant and rear wheels as in the ordinary type of car.

Owen Magnetic Means Car Longevity

There is just the gentle drawing forward, due to the magnetic force, acting across an air space, which starts the drive shaft revolving and in turn starts the car forward so smoothly that it is actually in motion before the passengers can feel the motion—and its speed accelerates with such a smooth but perfect gradation, that there is no jerk, no jar, to mar its exquisite softness of riding—no harsh impact of power impulse to wear out differentials, axles, their bearings, and also the tires.

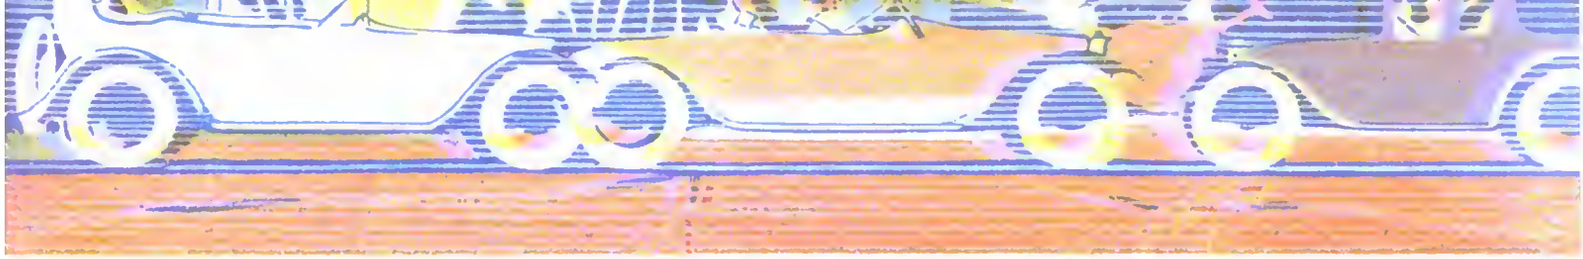
Coasting Qualities

Only when the engine is running faster than the propeller shaft is driving effort applied to the wheels. With the throttle closed the engine slows down to its idling speed and the car coasts perfectly free. The power is again applied by merely opening the throttle when the engine will increase its speed until it overtakes the propeller shaft and the magnetic lock again becomes effective.

Delightful Sensation — Safe

The coasting ability of the Owen Magnetic is not only a delightful sensation but is a wonderful aid in driving on slippery roads without the danger of skid-

Owen Magnetic Transmission permits the driver to run his car at any speed he desires, and control his clutch and brake as well, by simply moving a lever on the steering wheel. This gives an entirely new form of speed control, independent of the spark and throttle.



DRIVING THROUGH AIR

ding. Where there is a positive connection as in the ordinary type of car between engine and driving wheels, the engine upon closing the throttle acts as a brake on slippery roads—the change from driving effort to braking almost invariably means skidding.

In the Owen Magnetic car, closing the throttle does not produce a braking effect—it allows the car to coast perfectly free without driving effort or braking at the wheels. Because of this the danger of skidding on slippery pavements is very much reduced and the car can be driven with greater confidence and a greater sense of security than is true of the ordinary type of car.

Electric Brake

In the neutral position the motor is connected to act as an electric brake—here it becomes a generator, taking power to drive it and so braking the car. It will hold the car on any mountainous grade without wear of any parts. It cannot hold the wheels, thereby practically eliminating skidding. The electric brake holds the car down to an absolutely safe speed on the worst hills. The electric brake is an addition to the regular foot and emergency brakes.

Owen Magnetic Transmission Eliminates

The friction clutch, clutch pedal, transmission gears, fly wheel, separate starting and lighting systems and their clutches, gears, chains, connections and automatic devices are eliminated because the Owen Magnetic system does the work of all.

What It Does for the Engine

It cleans up the power plant, makes it more accessible. Makes all of its parts, such as valves, valve springs, carburetor, magneto, water pump, hose connection, tire pump and steering gear case most accessible.

In the Owen Magnetic Is Offered

ease of control, elasticity of power, constant torque, smooth riding at a thousand speeds—qualities which other manufacturers have sought in vain by multiplying cylinders.

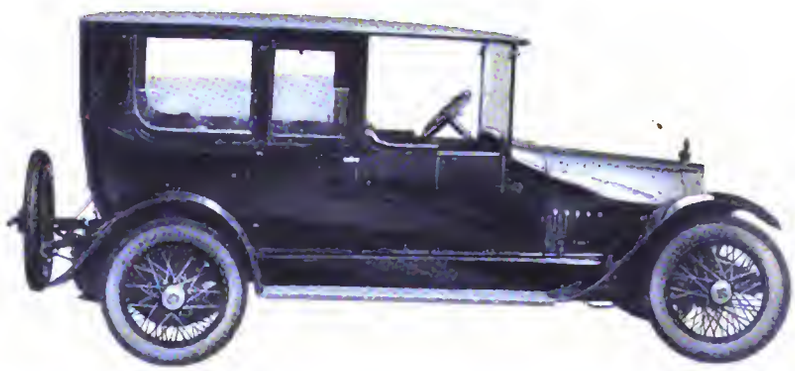
Unparalleled coach work, of the design and quality individual to only the highest priced foreign cars, characterizes the Owen Magnetic.

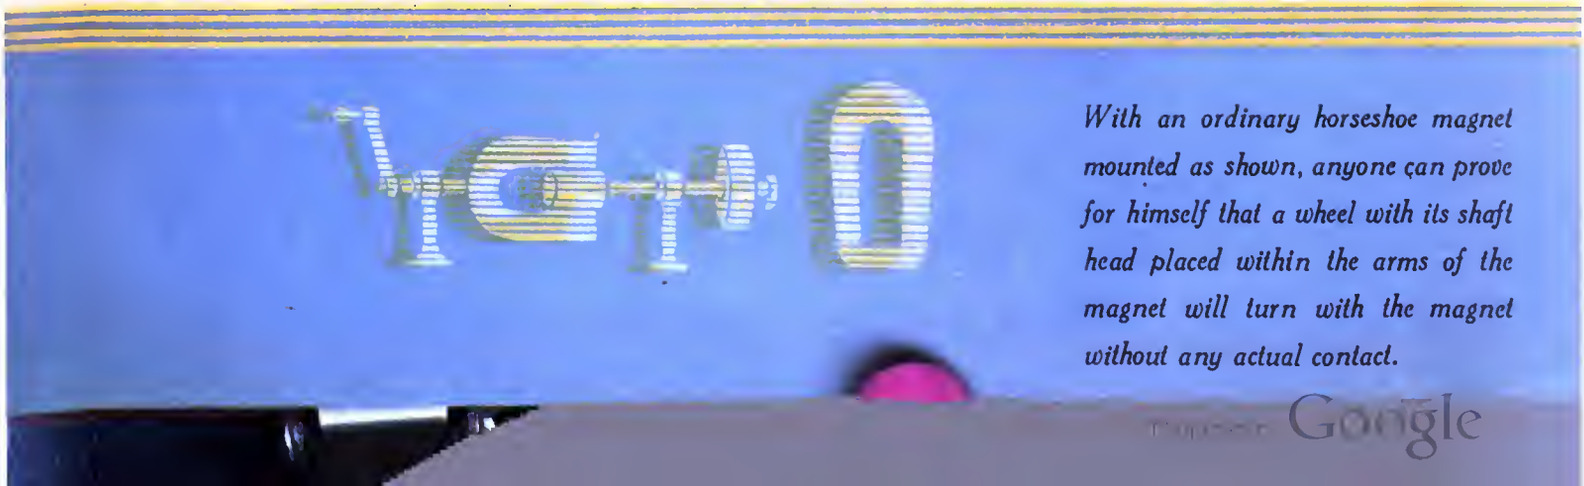
The Wonderful Control

The different controls of a motor car are accomplished on the Owen Magnetic by one small finger lever on the top of the steering wheel. This moves a drum controller to different positions and there can be no interference between any of these positions. You start, stop, increase, diminish or float along at any speed. No jerk nor jars like other cars. Only the smoothest riding action.

Complications Eliminated

There are no automatic cut-outs, regulators or roller ratchets, no chain or gear drives for any of the parts. Simply two ample sized dynamo machines direct connected and a drum controller, and require practically no





With an ordinary horseshoe magnet mounted as shown, anyone can prove for himself that a wheel with its shaft head placed within the arms of the magnet will turn with the magnet without any actual contact.

DRIVING THROUGH AIR

attention or adjustment. These replace the separate starting and lighting systems with their complicated means of driving and regulation—the friction clutch and its actuating mechanism—and the fly wheel.

Simple and Clean

The system is as simple and clean as it is possible to imagine. It accomplishes more desirable things than have ever before been accomplished with a motor car and with an infinitely less number of parts. Outside the simplicity of the system and the fact that it displaces forever the most complicated and objectionable parts of the prevailing type of motor car, there are many features that appeal to those that drive and ride in an Owen Magnetic car.

Action as Smooth as that from an Electric Motor

All power impulses of the gas engine are eliminated—the turning effort impressed upon the propeller shaft is exactly as uniform and smooth as that from an electric motor. No shocks nor jars can be transmitted through this absolutely elastic means of transmitting power.

Power Never Disconnected

From a standing start to maximum speed through all the range of power required from level road to the worst hill, the power between the engine and the propeller shaft is never disconnected, as is the case where clutch is thrown out, a gear change made and clutch engaged again. The car may be easily manipulated in traffic, on level roads, winding irregular grades, through the operation of the small finger lever which calls forth all the power of the engine for an instant or as long as is necessary.

It Performs Surprisingly

The car may be held on a grade by its engine power, the clutch generator slipping and holding with the aid of the electric motor ready to at once go forward upon opening the throttle. By closing the throttle slightly the car will move backward slowly and then at the will of the driver be stopped—then sent forward up to the maximum speed the grade will allow and all without disconnecting the power of the engine from the driving shaft.

Owen Magnetic Builders

The electric apparatus in the Owen Magnetic car is built by the General Electric Company, which concern has acquired a large interest in the patents covering this transmission. The combination of the General Electric Co. with The Baker R & L Company, manufacturers of chassis and body, whose history in building fine coaches for over sixty years is synonymous with quality, guarantees to the owner a product of the highest possible quality.

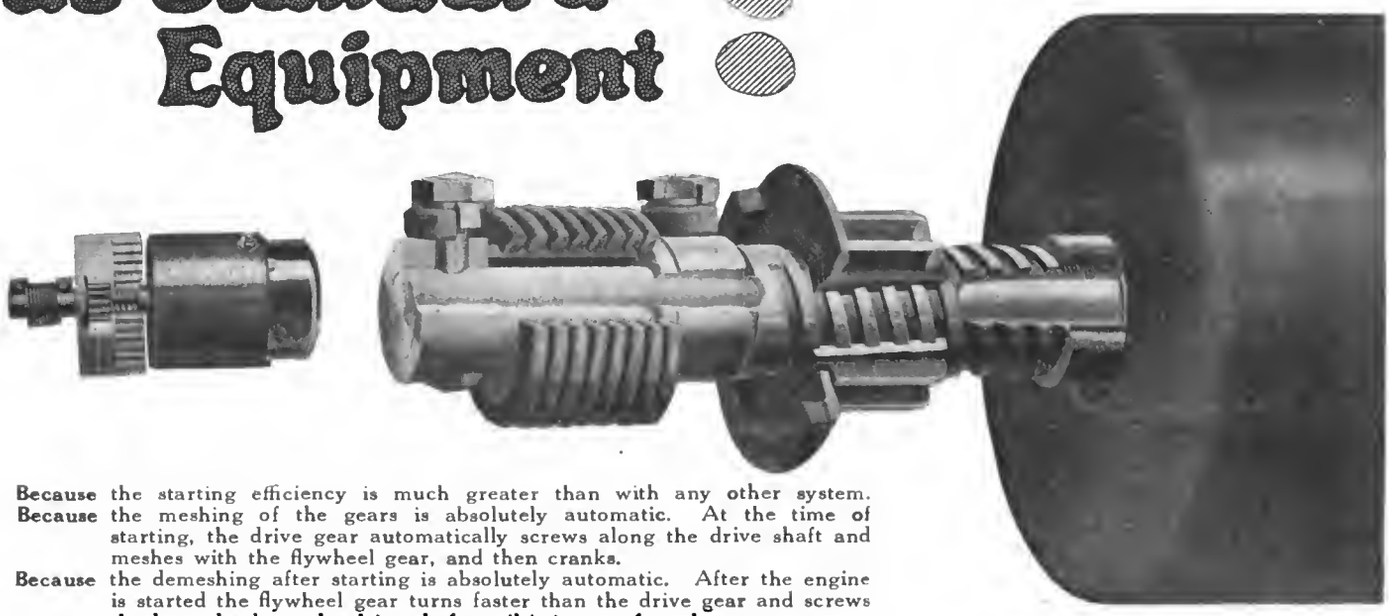
In the actual O... Transmission ... use an electro-magnetic field ... which can be ... solutely control... from the steer... wheel.

Why have 125 Car Builders adopted the ECLIPSE-BENDIX DRIVE as Standard Equipment?



Because the starting efficiency is much greater than with any other system.

Because the meshing of the gears is absolutely automatic. At the time of starting, the drive gear automatically screws along the drive shaft and meshes with the flywheel gear, and then cranks.

Because the demeshing after starting is absolutely automatic. After the engine is started the flywheel gear turns faster than the drive gear and screws the latter back on the drive shaft until it is out of mesh.

Because cast iron teeth without any chamfer not only make a great saving in cost, but are actually superior, being the simplest, most efficient and durable construction possible. The teeth are cut in the flywheel, which is a natural gear blank. Stripping of these teeth by accidental starting when the engine is running is impossible, because of the automatic demeshing action.

Because back-fires are automatically protected by the shock absorbing spring drive.

Because there is no over-running clutch to stick or slip.

Because there is no resistance or two-point switch to burn out.

Because there are no shifting levers and pedals, with their complications.

Because it is simpler and has fewer parts than any other starting system.

Because it eliminates chains, which stretch, break and get noisy.

Because it minimizes gear noise in cranking by driving through a spring.

Because it is absolutely silent when the engine is running, being absolutely disconnected.

Because it permits of using a simple, small generator for constant running.

Because it permits of cranking the engine with the most efficient of all starters—a separate electric starting motor—and also more evenly.

Because it makes the two-unit type of starting and lighting system superior to any other and the most popular of all.

Because it requires the minimum of care and attention during the life of car.

Because it is regularly supplied and used as standard equipment with the following starting and lighting systems, on over 125 different makes of motor cars, and also on a large number of marine and aeroplane motors:

A-B-C	Detroit	John O. Heinze	North Western	Splitdorf
Allis-Chalmers	Disco	Kemco	Remy	Wagner
Auto-Lite	Dyneto	Leece-Neville	Robbins & Myers	Ward-Leonard

What would have prevented most of the auto-mishaps you know of?

Wouldn't good brake lining have done it?

Careful drivers know or they are fast learning the false economy of friction-shy brake lining.

They are learning the advantage of Thermoid 100% brake lining—an advantage that may any time mean the difference between a close shave and a crumpled car—a narrow miss or a crushed body.

Thermoid HYDRAULIC COMPRESSED Brake Lining-100%

Brake lining that is not 100% is like a heart failure. A sudden shock—a Big Emergency—may mean death.

Thermoid Brake Lining has 100% gripping and holding power even when it is worn paper thin.

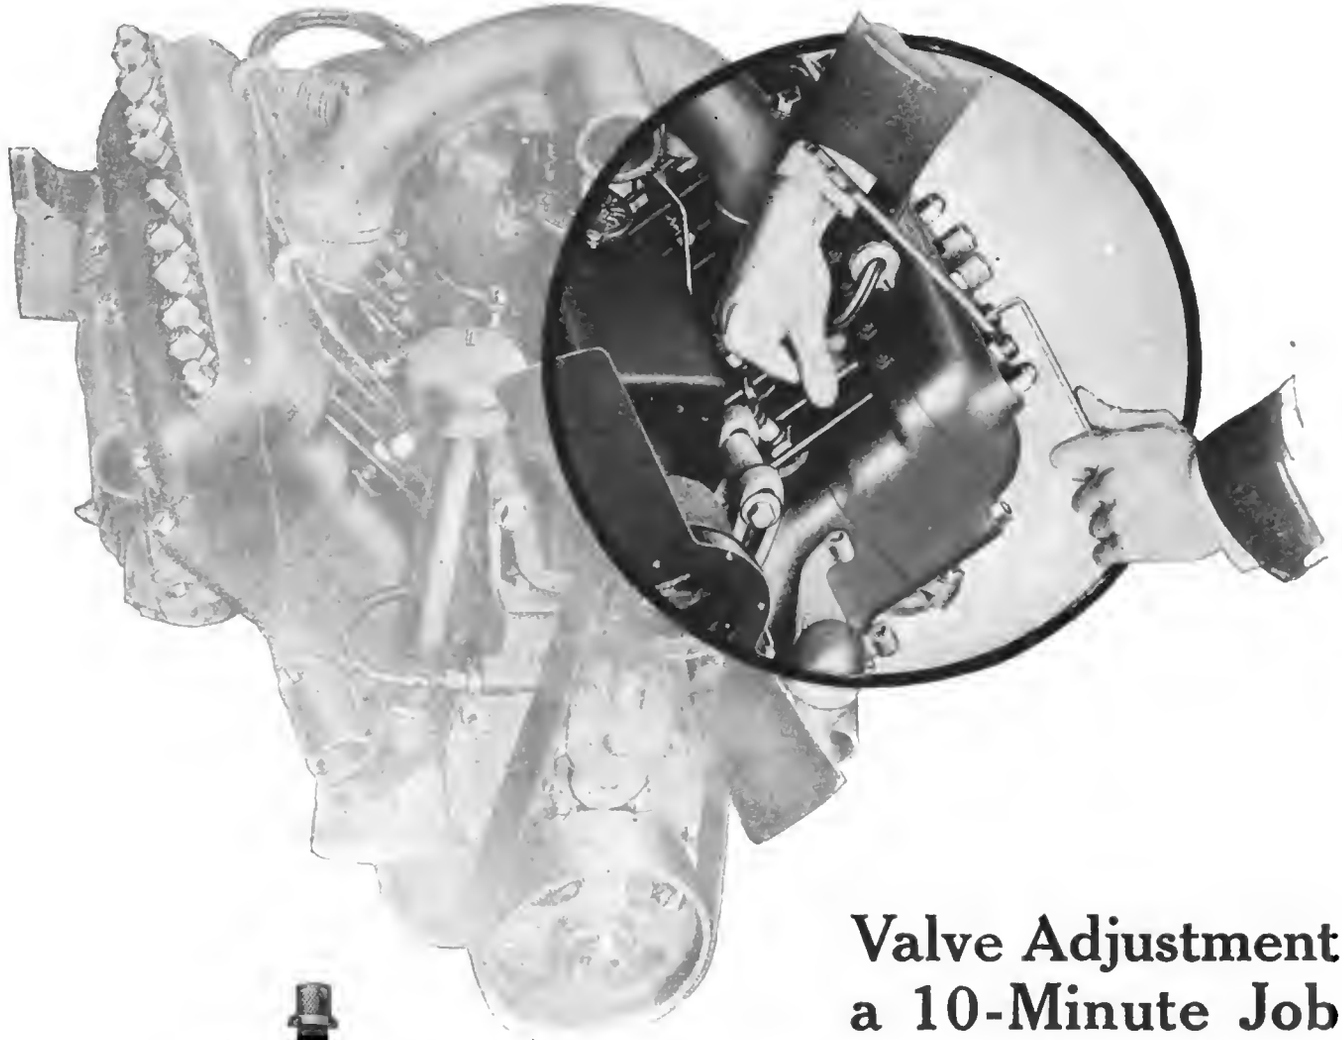
That means that, lined with Thermoid, brakes will hold, not only when the car is just being stopped but when it must stop quick or hit something.

Thermoid wears because it is cured under hydraulic compression into a solid substance of uniform density. It contains 50% more material foot for foot than do other kinds. Watch the brakes—remember that without a lining they are not brakes at all. Consider, too, how much better it is to see they are lined with Thermoid Brake Lining than to have a finely equipped motor crumpled into junk in an instant, or to have to race to a hospital with a child or adult that would not have been hit if the brakes had held.

Thermoid Brake Lining is absolutely guaranteed to give more satisfactory results and to outwear any other lining manufactured. Not affected by heat, oil, water, gasoline or dirt

OUR GUARANTEE:
Thermoid will make good or we will

Thermoid Rubber Company
Trenton, N. J.



Assembling of valve reciprocating parts. Note adjusting screw and spherical fulcrum at top, roller valve-lifter at bottom.

Valve Adjustment a 10-Minute Job

In Ferro V-Type Motors, the valve adjusting screws are on the top of the cylinder-head cover, right within easy reach.

All that is required for taking up valve clearance is to unscrew a cap, loosen a locknut and turn the adjusting screw.

The car-owner himself can adjust all the valves in ten or fifteen minutes.

This big improvement was made possible by placing the valves in the head and using detachable heads without valve cages.

It is but one of a number of features that make Ferro V-Type Motors so desirable.

Limousine Luxury With Your Present Open Car

Blackmore Door Curtain Openers give you all the advantages of a car enclosed in wood or glass. When curtains are attached, they enable you to open your doors all the way up. No buttons to fuss with, no curtains to bother you. No "ducking" or stooping to enter or leave the car. These patented Blackmore Openers are simple inexpensive steel supports for automobile door curtains. They enable the open body to offer every advantage of the closed limousine. Once you have attached them you can forget all about your curtains until spring. The openers can be instantly detached and put away with your curtains.

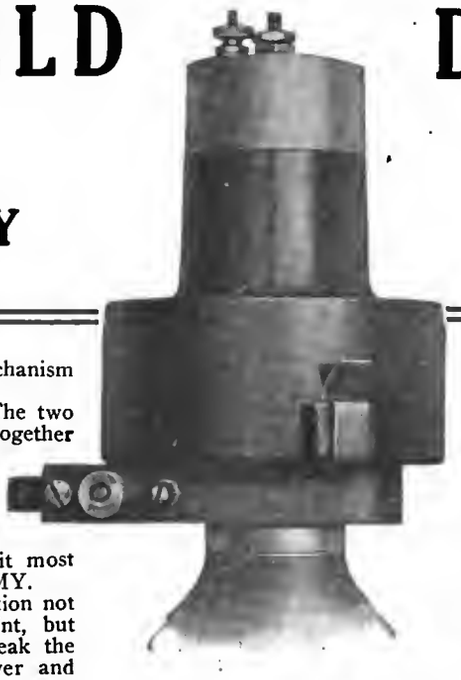
PITTSFIELD DISTRIBUTOR

SIMPLE DURABLE ABSOLUTELY FOOL-PROOF



An open circuit and a breaker mechanism independent of springs.

Look at these three illustrations. The two small platinum points are forced together and then forced apart by the revolving cam. The cam is so shaped that while the "make" or contact is firm it is of much shorter duration than the "break" action, thus leaving an open circuit most of the time. This means ECONOMY.

Notice particularly that the cam action not only drops the lower contact point, but pushes up the contact point, to break the contact; also that it lifts the lower and drops the upper to make contact. This means POSITIVE UNFAILING ACTION—MECHANICAL ACTION.

The cam action in Fig. 1 is designed for a 4-cylinder engine; the cam action in Fig. 2 is designed for a 6-cylinder engine; the cam action in Fig. 3 for an 8-cylinder engine. Count the cams!

Electrical and mechanical lags are practically eliminated by this simple, positive action, and timing synchronization made as nearly perfect as is humanly attainable.

The whole ignition outfit is simple, compact, and made into a single unit, including the coil.

A REAL RESOLUTION

that will in no way be original but nevertheless worth money to you, will be to resolve what hundreds of others are sure to do—always do—and that is; continue for another year to come to headquarters for service that puts money to your name in the bank.

HERE'S WHY

AXLES—Front and Rear, $15.00 up.

BODIES—Detroiter Roadster 1915, $45.00; 1914 Roadster for Ford, $15.00; Warren 1913 Roadster, $20.00; Crescent T C 5 passenger 1914, $50.00; 1913, $35.00; 1912, $25.00; Cadillac T C 5 passenger 1912, $00.00; 1911, $40.00; 1914 Phaeton, $65.00; Oakland 1911 close coupled, $20.00; 6-60 second hand, $40.00; Havers T C 5 or 7 passenger, $50.00; Detroiter T C 5 passenger 1914, $50.00; Carterear T C 5 passenger M/R 1913, $30.00; N/M 1912, $30.00; Keeton 1915 T C 5 passenger, $65.00; 1913 T C 7 passenger Franklin Front, $50.00; Abbott Cloverleaf Roadster, 4 passenger, $125.00

Many others in stock. Send for measurement chart.

CARBUBETORS—Kingston and Holley 1¼" top intake, $4.50; for Fords, $5.40; Bennett 1¼", $3.95; Stromberg Model K-1 1", $8.20; Rayfield Model C-3 1¼"; Stromberg Model L-2 1¼"; Zealth Model L-5 1¼"; Master 1½"; each $12.00.

COILS—Briggs, Michigan and Splitdorf, 4 cylinder, $6.00; Remy Models RD, RL, and S and Splitdorf, 6 cylinder, $6.00; Splitdorf Transformer Coils for any low tension magneto, $8.00.

FRAMES—All sizes at $10.00.

MOTORS—Continental 4 cylinder, 45-53 H. P., complete with Magneto, Coil, Clutch and Transmission, at $200.00; Northway, 35 H. P., Unit Power Plant, with High Tension Magneto Ignition and Lighting Unit, price $175.00; Krit 1915, Unit Power Plant, $125.00, two speed, $75.00; Perkins 4 cylinder, 18 H. P., $60.00; Jackson overhead valves, Unit Power Plant, $75.00; Crescent, 4 cylinder, 50 H. P., Unit Power Plant, price $150.00.

RADIATORS—V-shaped for Ford, Honeycomb, Brass, $23.50; German Silver, $24.50; Abbott Detroit, all models, $30 00; Studebaker, "25," $22.50; 6 cylinder, 1914, $25.00; Paige Model 25, $22.50; Oakland, many models, each, $22.50; Benham, $30.00; King Model E, 1916, $30.00; Everitt 30, $22.50; Crescent 4 and 6 cylinder, $30.00.

RIMS—Stanweld S. S. 36 x 4½, $5.00; 34 x 4½, $4.50; 32 x 3½, $2.50; Firestone Q. D. Clincher 36 x 4½, $2.40; 36 x 4, $2.30; 34 x 4 Universal, $2.30; Baker 36 x 4 and 34 x 4 S. S., each, $2.60; 32 x 3½ S. S., $2.55; Booth Clincher 36 x 4½, $4.00; 36 x 4 and 32 x 4, $2.30; Detroit 34 x 4 Clincher, 36 x 4 S. S. and 1912 S. S., each, $2.70; 32 x 3½ Clincher, 1912 S. S. and 30 x 3½ 1912 S. S., each, $2.40; Kelsey 32 x 3½ No. 20 Clincher and No. 30 S. S., each, $2.30; 34 x 4 No. 30 Clincher, $3.60.

TOPS—One man mohair with inside curtains and dust boot. Will fit Overland 75, Dort 1914, King 4 cylinder, Maxwell 25, 1914, Briggs-Detroiter, Dodge 1915. Regular $75.00 value; our price, $37.50. Many other sizes, some as low as $10.00. Send for measurement chart.

TIRE SAVER JACKS—Only $1.89 per set.

TRANSMISSIONS—Mnncle, 4 speed, center control, each $50.00.

AUTOMOBILE TURN TABLE—Ernst All Steel, 14 ft. Bargain.

WINDSHIELDS—Many models and sizes; plain vision and other types strictly up to date; to fit practically any make of car or truck. Prices from $8.00 to $13.00. Write for quotations and detailed specifications.

WHEELS—Both Front and Rear, all sizes, from $3.00 up.

SHOCK ABSORBERS—Mondex, per set, $12.00. Fittings extra.

MAGNETO REPAIRING—We can repair practically any make of magneto furnishing new parts where required.

Write for our Bargain Bulletin.

115 Grand River Ave., Detroit, Mich.

AUCTION

We will, commencing Wednesday, January 3d, 1917, and continuing Thursday, January 4th, 1917, at 10:00 A.M. each day at Waterloo, Iowa, sell at public auction entire plant of L. C. Erbes. Inventory value over $350,000.00.

Good Will and Service

At the commencement of sale, we will offer the good will and service of the Milwaukee Motor, consisting of Service parts, jigs and dies, blue prints, names of car manufacturers who have used Milwaukee motors in tbeir cars and list of car owners. Approximately 20,000 Milwaukee motors were manufactured and sold.

We will next offer Service of the Cutting and **Clark-Carter** cars, of which approximately 5,000 cars were manufactured. Also repair parts for Mason cars. The service of all the above is now being conducted and kept intact. Each service will be sold separately. The services are doing a prosperous and profitable business.

Immediately after sale of Service Departments, we will sell tbe following items:

150 Milwaukee unit plant motors complete witb transmissions and clutches.
40 assembled one ton truck chassis.
15 one ton trucks complete with bodies.
35 roadsters and touring car chassis.
All of tbe above cbassis are equipped witb Milwaukee motors.
200 touring car, roadster and truck bodies, upbolstered and in white.
400 sets Lewis springs, 100 sets Timken, Hess and Lewis front and rear axles, Warner transmissions, 500 truck and touring car frames, aluminum crank and transmission cases, 250 Warner and Lavigne steering gears.
300 sets 34 x 4, 36 x 4, 36 x 4½ wheels with Firestone, Stanwell and Baker demountable rims.
Latbes, drill presses, milling macbinery machines, large stock of tools, turret lathes.

Commencing Thursday, January 4th, at 10 A. M.
Supplies and Parts

An enormous quantity of standard brands and staple parts, consisting of leather, leatherette, linings, mohair, seat cover material, duck, etc. Sbeet celluloid, wire, cable and conduit, bows, one man top sets, curled hair, American and Berry body and coacb varnishes, finishes, paints and enamels, Bosch, Remy, Splitdorf, New Departure and F. & S. bearings, Remy coils, piston rings, motor parts, magnetos, earburetors, mufflers, 100 Northeast, Jesco and Apple starters, spot lights, crank cases, gauges, electric starters, batteries, pumps, draw shafts, gears, ball bearings, boods, fenders, crank sbafts, clutcbes, grease cups, axles, springs, transmissions, steering wbeels, frames, levers, tool sets, springs, leaves, apark plugs, apeedometers, cocks, tool boxes, spark coils, control levers, sprockets, chains, brass tubing, pipe, gear sbifts, crank shafts, valves, switches, 100 Rain-vision windsbields, 150 radiators, 500 motor horns, trucks, oval gas tanks, gasoline tanks, tires, die cast bearings, etc.

Also an enormous quantity of brass, aluminum and eopper castings, parts, and supplies, nuts and bolts, screws, washers, rubber goods, etc. A very large quantity of machine and rougb castings, motor castings, brass and copper scrap, junk, oils, greases, suppliea, etc. Also a large quantity of tool steel, sbaftings, pulleys, hangers, trucks, steel tanks, enameling ovens, cranes, scales, fire extinguisbers, cusbions, etc., in fact, parts and supplies of every description.

Terms and Conditions

Terms of sale strictly cash. Positively no checks will be accepted unless certified. All goods sold to be removed at tbe risk and expense of purchaser. All merchandise not removed at time specified by auctioneers will be re-sold and deposit of purchaser will be forfeited without further notiee.

Please Note.

Nothing will be sold at private sale at any time prior to date of auction sale set. Everytbing will positively be sold at this sale witbout any reserve or restriction. Sale will be beld at Waterloo, Iowa, on Wednesday, January 3d, and Thursday, January 4th, 1917. Excellent loading facilities. Trackage and sbipping platform adjoining building.

Patents and Patent Attorneys

Mr. Charles Binks of C. Binks, Ltd., Eccles, England,

is prepared to sell the American Patents and Rights of his Carburetors. Any one purchasing these rights can build up quickly in America as successful a business as is carried on in England. Patents consist of Motor Cycle and Car Carburetors for Petrol, Carburetors for Parraffin and Heavy Fuels for Cars and Trucks. Better results obtained than from any others. Winner of the English "Manufacturers Trophy" and *most* records. Price, $10,000 for the entire interest and future improvements. A certain fortune for a live manufacturer. $500 paid down will secure the option to purchase for one month. **C. Binks,** 67, Snowdon Road, Eccles, England.

THE ADVERTISERS' INDEX is published as a convenience and not as a part of the advertising contract. Every care will be taken to index correctly. No allowance will be made for errors or failure to insert.

From the southern cape of Africa to Russia's northmost road, then east and west until the globe is circled, there is but one carbureting device known everywhere—THE ZENITH.

For nine years this Plain Tube carburetor has been building a commanding reputation on Europe's foremost cars. In the far-off places and in the centers of the industry the Zenith is delivering uniform results continuously. Five separate Zenith factories are proof conclusive.

Over fifty American manufacturers in the motor industry now equip with Zenith for service on motor trucks, touring cars and aeroplanes. They know its sales and service value. It gives results—the answer.

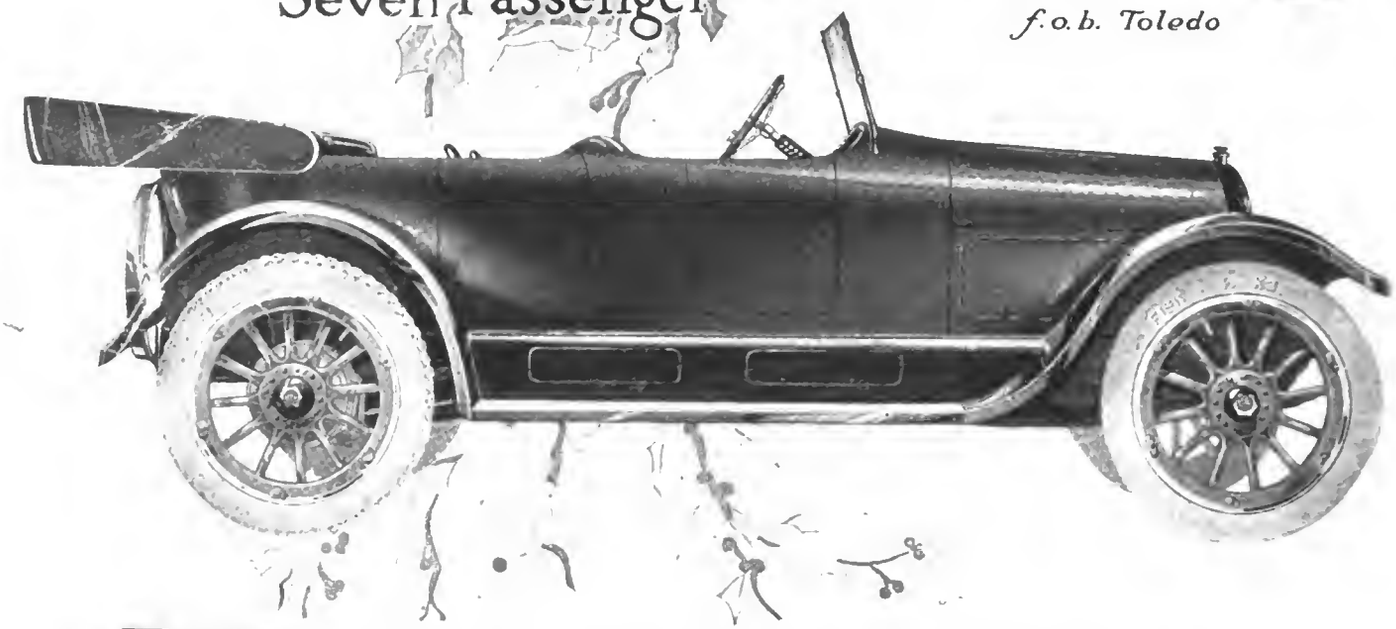
Willys SIX

Seven Passenger

$1325

f. o. b. Toledo



BETTER PERFORMANCE AT SPEEDS YOU NORMALLY USE

The Willys-Six, compared with any other six of its size, will give you

—higher power at normal driving speeds.

—faster pick-up at normal driving speeds.

—smoother climbing without rushing the hills.

—greater smoothness in high gear at very slow speeds.

The new Willys-Six attains a speed of 20 miles per hour at 768 r.p.m.—40 miles per hour at 1536 r.p.m.

In design, finish and appointments it is new, beautiful, complete and up to the minute.

It sets a new high mark in easy riding comfort.

Long forty-eight inch cantilever rear springs, perfect balance, long wheelbase—125 inches, big tires—4½x35 inches—provide the utmost ease and luxury of riding comfort.

And the low deep-cushioned seats are built over improved seat springs—each spiral separately encased and thus air cushioned and checked against rebound.

The price, $1325, is possible because Willys-Six shares the economies that we obtain by building a complete line of automobiles in our factory

—with *one* executive organization.

—*one* purchasing power.

—and selling them with *one* sales expense through *one* dealer organization.

The Willys-Overland Automobiles represent an exceptional buying opportunity for the public—an exceptional selling opportunity for automobile dealers.

The Willys-Overland Company, Toledo, Ohio
